THE

GARDENER'S AND BOTANIST'S

DICTIONARY.

[CLANDESTINA. See *Lathræa*.

CLARY. See *Salvia*.

CLATHRODES and CLATHROSTASTRUM. See *Clathrus*.

CLATHRUS. A genus of *Fungi*, instituted by Micheli.—Roundish, consisting of a reticular, windowed, hollow body, the ramifications connected on every side.

There are only four species recited by Linnæus. Mr. Hudson has eight species. Seven species are figured by Bolton in t. 93 and 94.

In Dr. Withering's Botanical Arrangement, the name *Trichia* is adopted from Haller, and he has eleven species, comprehending some of Linnæus's Mucors, the *Sphærocarpus* of Bulliard, and the *Lycoperdon rufum* of Dicleton.

The essential character here given is, that it grows in clusters, mostly fixed to a membranaceous base. Capsules globular or oblong. Seeds escaping from its whole surface, through openings made by the separations of the fibres. They are found chiefly on rotten wood.

CLAVA HERCULIS. See *Zanthoxylon*.

CLAVARIA. A genus of *Fungi*, one of the lowest order in the scale of vegetation, differing sometimes very little in substance from the rotten wood whence it issues. It is a tender, oblong body, of one uniform substance.

Thirteen species are recited in the *Systema Vegetabilium*: five simple, and the rest branched. In Withering's Botanical Arrangement there are twenty species, besides many varieties. They are figured by Schæffer, Micheli, Bulliard, Bolton, Dickson, &c.

In Dr. Withering's Work, the essential character is—Fungus oblong, upright, club-shaped. Seeds emitted from every part of its surface.]

CLAYTONIA. (*From Mr. John Clayton, who collected plants chiefly in Virginia, and sent them to Gronovius, who published them in his Flora Virginica.*) *Gronov. Lin. gen.* n. 287. *Rudb.* 505. *Sibrth.* 402. *Gærtn.* t. 129. *Juss.* 314.

Ord. 5. 1. Pentandria Monogynia.

Nat. order of *Succulentæ*. *Portulacæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* bivalve, ovate, transverse at the base.

COR. *Petals* five, oncumbent, with claws, emarginate.

STAM. *Filaments* five, subulate, erect, a little shorter than the corolla, each inserted into the claw of each petal. *Anthers* oblong, incumbent.

PIST. *Germ* roundish. *Style* simple, the length of the stamens. *Stigma* trifid.

PER. *Capsule* roundish, three-celled, three valved, cellific.

SEED. three, round.

VOL. I. PART II.

OBS. C. portulacaria, *having obovate petals, six style, and three simple stigmas: is removed from this genus.*

ESSENTIAL CHARACTER.

Cal. two-valved. *Cor.* five-petalled. *Stigma* trifid (or three). *Caps.* three-valved, one-celled, three-seeded.

SPECIES.

1. Claytonia virginica.
   Lin. spec. 294. *Retz. fasc.* [illegible]
   Gron. Virg. 102. *t.* 3. [illegible]
   Bart. Trav. 284.
   Leaves linear-lanceolate.
2. Claytonia sibirica.
   Lin. spec. 294. *Pall.* [illegible]
   Amœn. fasc. 4. 80.
   Linnæus. *All. specific.*
   Leaves ovate.

DESCRIPTION.

1. Has a small tuberous root, which sends [illegible] stalks up the spring, about three inches high, each two or three succulent narrow leaves [illegible] inches long, of a deep green colour. At the top of the stalk four or five flowers are produced in a loose bunch. Petals spreading, white spotted with red on their inside. The flowers appear in april, and the seeds ripen in june. It grows naturally in Virginia, whence it was sent by Mr. Clayton, and cultivated by Mr. Miller before the year 1759. The leaves are linear, and the calyxes obtuse. There is a variety with lanceolate leaves, and acutish calyxes.*]

2. This is a low plant, seldom rising more than two or three inches high. The root is tuberous, as in the other.

[Root-leaves petioled, nerved, very smooth. Scape declined. Stem-leaves two, opposite, sessile, between which are two one-ranked racemes, whilst tender these are revolute, and one of them is two-leaved. Flowers red. Stamens inserted into the claw of the petals.†]

PROPAGATION AND CULTURE.

The plants are both propagated by seeds, and also from offsets sent out from the roots: the seeds should be sown on a shady border of light earth, or in pots filled with the like mould, soon after they are ripe: for if they are kept out of the ground till spring, the plants will not come up till the next year; whereas those which are sown early in the autumn, will grow the following spring, so that a whole year is gained. When the plants come up, they will require no other

* Host. Aust.

† Linn. Syst.

care but to keep them clean from weeds; and in the autumn, if some old tanners bark is spread over the surface of the ground, it will secure the roots from being injured by frost, but in mild winters they will not require protection.

The best time to transplant the roots is about Michaelmas, when they are inactive; but as they are small, a great care is not taken in opening the ground, the roots may be buried and lost, for being of a dark colour, they are not easily distinguished from the ground.

[Clavisenia Portulacaria. See Portulacaria.

CLEAVERS. See *Galium Aparine*.]

CLEMATIS. (*From κλημα, sarmentum, because it climbs trees, by means of its plant-twigs, like vine of the vines.*)

Hall. 13 7. Polyandria Polygynia.

Nat. order of *Multisiliquæ*—*Ranunculaceæ*. Juss.

GENERIC CHARACTER.

Cal. none.

Cor. *Petals* four, oblong, lax.

Nect. *Filaments* very many, subulate, shorter than the corolla. *Anthers* growing to the side of the filaments.

Pist. *Germs* very many, roundish, compressed, ending in awl-shaped styles, longer than the stamens. *Stigmas* simple.

Peric. none. *Receptacle* headed, hairy.

Seeds very many, roundish, compressed, furnished with the style in various forms.

Obs. Clematitis T. *Petals* intermediate petals; *the seeds have* [illegible] *long whisky bristle.*

Flammula *has eight petals; the seeds orbicular, with a very long feather.*

Vincella *has five oval, deltoid petals; the seeds have a naked crested point.*

C. virginiana & dioica *are both dioecious.*

ESSENTIAL CHARACTER.

Law. cadmea. 345.

Leaves palmate, leaflets lanceolate, three-parted, petioles very long.

DESCRIPTION. *Linn.*

The Virgin's Bowers are chiefly climbing shrubs, some of them however are erect. Leaves opposite, simple, ternate or unequally pinnate. Flowers paniculary, more frequently terminating, solitary, but more frequently in corymbs; in many species abortive. In a few furnished with a turbinate bifid calyx, in most with a little from the petals.

1. This has a climbing stalk, rising to the height of eight or ten feet, sending out branches from every joint, whereby it becomes a very tickle bushy plant. Leaves sometimes simple, sometimes subsequently ternate, serrate. [According to Linnæus they are usually simple, petioled, grow several together from the same joint.] The flowers come out opposite to the leaves. The flowers are produced from the side of the branches; they are large, of a herbaceous colour, and under each is a ternate, pentaphyllous, or nine calyxes.] They appear at the end of December, or beginning of January, & grows naturally in Spain [where it was observed by Clusius in 1565. In 1596 it was cultivated by Gerarde,] who calls it *The Vine of Canada*. Johnston names it *Hortus Spanicus Pomponii*, *Dod.* and Parkinson, *Spanish Pomponius*.

2. Stems very slender and weak, dividing at the joints, whereby they come out into many ties, which will rise to the height of eight or ten feet. The leaves branch out into many divisions, each having a slender petiole, with three at the entire leaflets, four leaflets generally arise from the same joint, two on each side; the two below have three of these divisions, so that they are composed of nine leaflets; but the two upper have only two opposite leaves on each side, between these are three slender petioles, each supporting one flower. [According to Linnæus, the lower leaves are conjoined, the middle three-lobed, the upper pinnate, the floral leaves ovate. Petioles thorny behind, very obtuse, channelled on the side.] Flowers of a dark wine-cup purple, or blue, or bright purple or red. It grows naturally in the woods of Spain and Italy [and was cultivated in 1569, by Mr. Hugh Morgan.] Gerarde calls it blue or red-flowering Indian Bower, from its appetite to make bowers of arbours in gardens.]

There are four varieties cultivated in the nurseries. 1. Single blue. 2. Single purple. 3. Single red. 4. Double purple. They flower in June and July, but the seeds seldom ripen in England. The last continues to the end of August.

3. Rises only three or four feet high. The leaves have one leaflet, three or each footstalk. The flowers come out at the joints of the stem, are white, and make no great appearance. It flowers in May, and grows naturally on the mountains of Italy. Mr. Miller received it from Monte Baldo.

4. [Stems many, slender, farmentose, round, striated, prostrate or climbing. Leaflets three-lobed, varied to the petiole, smooth, paler underneath, entire, sometimes gashed, but commonly sometimes bifid, and waved; the nerve of the three-lobed one from the middle, but nearer to the inner side. Petioles solitary, axillary, with one pair of simple leaves in the middle; flowers solitary, nodding, corniculate, green on the outside, never opening except at the end, where the petals are bent back; they are of a greenish white on the outside, and very pale green within. The filaments scarcely emerge from the corolla, are bristle-shaped, hang at first green then brown, [and] the anthumic, of a brownish green colour.]

Native of Carolina and Virginia. It is in Banister's catalogue of the plants of Virginia sent over in the year 1680. In 1732, it was cultivated by Peter Collinson, M. D. at Eltham; and Mr. Miller received the seeds from both countries. It flowers from June to September, and if the autumn prove warm, perfects seeds well ripen.

5. This has weak stalks, which rise near four feet high, and by their scalpers fasten themselves to neighbouring plants. The flowers come out singly [on] the sides of the branches upon thick footstalks, one or two pair of leaves [at the joints] and sharp-pointed. [The] is emitted, and has [a]

[Thunberg] [Japan] [Native of] [Florida and Japan.] [It flowers] [in gardens at the] [September.]

5. This has weak climbing [stalks.] Leaves of seven or eight feet, when [full grown] leaves produced on short petioles, which are angular and thorny-pointed.

[According to the description of Dillenius, they resemble the upper leaves of smallage in shape, but they are glaucous on both sides, and have much softer and thinner hairs so that they are easily either seen or felt: the petioles and ends of the twigs have also the same delicate pubescence. Flowers drooping; petals bent back, hoarily hairy, villose within of a yellowish green colour, with a tinge of purple on the upper side. Flowers collected into an oblong panicle, with [green] purple anthers yellow at the [top.]

6. Rises from [six] to twelve [feet] and was discovered by Tournefort in the Levant, where he found the seeds in the royal garden at Paris. It was cultivated [in] here in 1732, by James Sherard, M. D. at Eltham. [Stems.] Leaves ternate; leaflets cordate-ovate, crenate, trifled. Peduncles branching, subcompound. Flowers yellowish, glaucous.—Native of New Zealand; found in Charlotte Sound, november 1773.]

7. Stems climbing, very high. Leaves ternate; leaflets many but deeply [cut] angular, naked, cordate, veined; floral leaves simple, five together, or universal, quite entire, three-lobed or undivided. Peduncles simple and three-flowered in the [axils.] Corolla white, spreading, [quinque]-partite; petals ovate-oblong, not [connate], spreading. Stamens and

[Willdenow.] [Host. Austr.] [Host. Ital.] [Host. Austr.] [Host. Ital.] [Host. Austr.] [Host. Ital

pistils yellowish white. The petiolules twist about and serve as tendrils to elevate the plant. The female flowers have filaments, but the anthers are destitute of pollen".

Loureiro asserts that the flowers are hermaphrodites, and that the fruit are five in number, of an ovate and obtuse shape, with a straight hairy tail, about the same length with the stamens.

Native of North America, also of Japan and Cochinchina. Cultivated in 1769, by Mr. James Gordon. It flowers from June to August.

9. Stem striated, purple, smooth. Leaves opposite, petioled, biternate. Leaflets pedinled, pinnatifide, ovate, entire or lobed, villose, the middle one largest. Petioles pedoliate at the base, terminating in a branch, spreading out horizontally. Flowers axillary, pedunculed, solitary. Peduncles villose, one-flowered, longer than the leaves. Corolla large, hanging, funnel-shape; petals five, minute, yellowish. Stamens five, purplish. This differs from *C. virginiana* in having decompounded leaves, acute leaflets, and ovate [illegible]. Native of Japan.

10. Stem [illegible] produced almost [illegible] 96, by John Fothergill, M. D. [illegible] part of the year.

Stem [illegible] striated purple villose. Leaves [illegible] pinnate joint, petioled. Leaflets on short [illegible] petiolules, equally serrate from the middle to [illegible] ovate, villose, the middle one largest. Petioles [illegible] villose, the middle one larger. Peduncles [illegible] axillary, pedunculed, capillaceous, [illegible] flowers from the joints, pedunculed, [illegible] purple. Peduncles [illegible]-flowered, the length of the leaves. This differs from *C. virginiana* in having the leaflets not cordate, but drawn to a point at both ends, the flowers cylindric, not ovate and [illegible]. Native of Japan.

11. This has slender [illegible] climbing [illegible], rising to the height of ten or twelve feet. Leaves trifoliate, [illegible] on each side the stalk, the leaflets are [illegible] ovate and entire, having three or five longitudinal [illegible]. The peduncles are produced at the [illegible] the petioles, one on each side [illegible] horizontally, extending [illegible] divide and branch [illegible] pairs of small footstalks [illegible] which divides again [illegible] a single flower [illegible] four or five inches [illegible] top, so that they [illegible] petals which are reflexed [illegible] all stand erect [illegible] about eighty seeds disposed in a head; [illegible] three-cornered and compressed, with [illegible] fringed with many white hairs".

Native of the West Indies, and also of Cochinchina, climbing very high without tendrils. It was sent to Mr. Miller from Jamaica, by Dr. Houstoun.

12. This shrub climbs as high as twenty feet by means of the twisted petioles. The younger shrubs are slightly hairy, flexible and purple; the old ones are the thickness of the finger, deeply grooved, and of a whitish colour. Leaves opposite, spreading, on long petioles; they consist of two pairs of leaflets with an odd one, leaflets ovate, acuminate, sometimes cordate, entire, serrate, or lobed, of a yellowish green colour, somewhat shining, veined on the under side. Flowers in axillary racemes, conjugate, leafy, dividing into three, then into two smaller branches; sweet-scented. Petals four, cross-shaped, (sometimes five, fourth, emarginate, spreading, a little rolled back) yellow, on the upper side of a pale sulphur colour, underneath greenish. Filaments the length of the corolla, upright; anthers oblong, whitish". Seeds about twenty, covered with a membranaceous thin reddish coat, with whitish hairs scattered over it, and ending in a very long plumose tail, when the coat, which is not open of itself, is taken off, the seed appears to be cuneiform, tangibly tenacious, and of a pale yellow colour.

9. This in its appearance is very like the common

[illegible] and [illegible] ¹ Hort. Ken. ² Hunting. ³ Hunting. ⁴ Loureiro. ⁵ Gærtner.

sort, but the leaves are broader, and grow by threes on the same foot-stalk, whereas in that there are five or seven leaflets on each leaf. The flowers appear at the same time, but the seeds do not ripen in England, unless the season be very warm. There is little beauty in this sort. It is a native of North America".

12. This is rather creeping than climbing. It is lower and more tender than the foregoing; leaves smaller, with five and seven pinnæ, or three-lobed, or three-leaved; leaflets ovate-lanceolate, with few gashes, and one or two teeth. Pedunicles compound, branching. Stipules numerous, ferrate. Petals lanceolate, white, marked with lines, burning'. Native South of Spain, Italy, the Grisons, &c. It flowers from July to October. Cultivated 1597, by Gerarde.

13. Perennial. Leaves opposite, leaflets usually five pairs, sessile, linear, [illegible] rigid, trifacial, [illegible] undivided, but sometimes [illegible] or trifid. Flowers as in the next species. Magnol and Ray determine it to be a variety of *C. Flammula*, but I, says Linnæus, should rather suppose it to be a variety of *C. [illegible]*, changed by the soil'.—Near Montpellier, Nice and Venice.

14. Perennial. Stems herbaceous, annual, round, scarcely branched, from three to five feet high, terminating in a panicle at top. Leaves opposite, pinnate; leaflets from two to four pairs, with an odd one at the end, petioled, lanceolate or ovate, acute, the upper surface smooth and green, the lower somewhat villose and glaucous; they are entire, seldom two-lobed. Stipules minute at the division of the peduncle. Petals white, oblong, four in number, sometimes five, obtuse, somewhat villose, a little longer than the stamens. Seeds few (from one to three or four, seldom more), dark brown, smooth, orbicular, much compressed, with a long, yellowish, plumose tail.

Linnæus remarks, that the umbels of flowers are upright and full.

The flowers come out in June, and the seeds ripen in September.

[Native of France, Switzerland, Silesia, Austria, Carniola, Hungary, Tartary. Cultivated in 1597, by Gerarde.

15. The variety which Mr. Miller makes a species, under the name of *C. Bipinnata*, differs only in having but two or three pairs of leaflets, which are narrower and [illegible] further asunder; thicker stalks, and larger flowers.

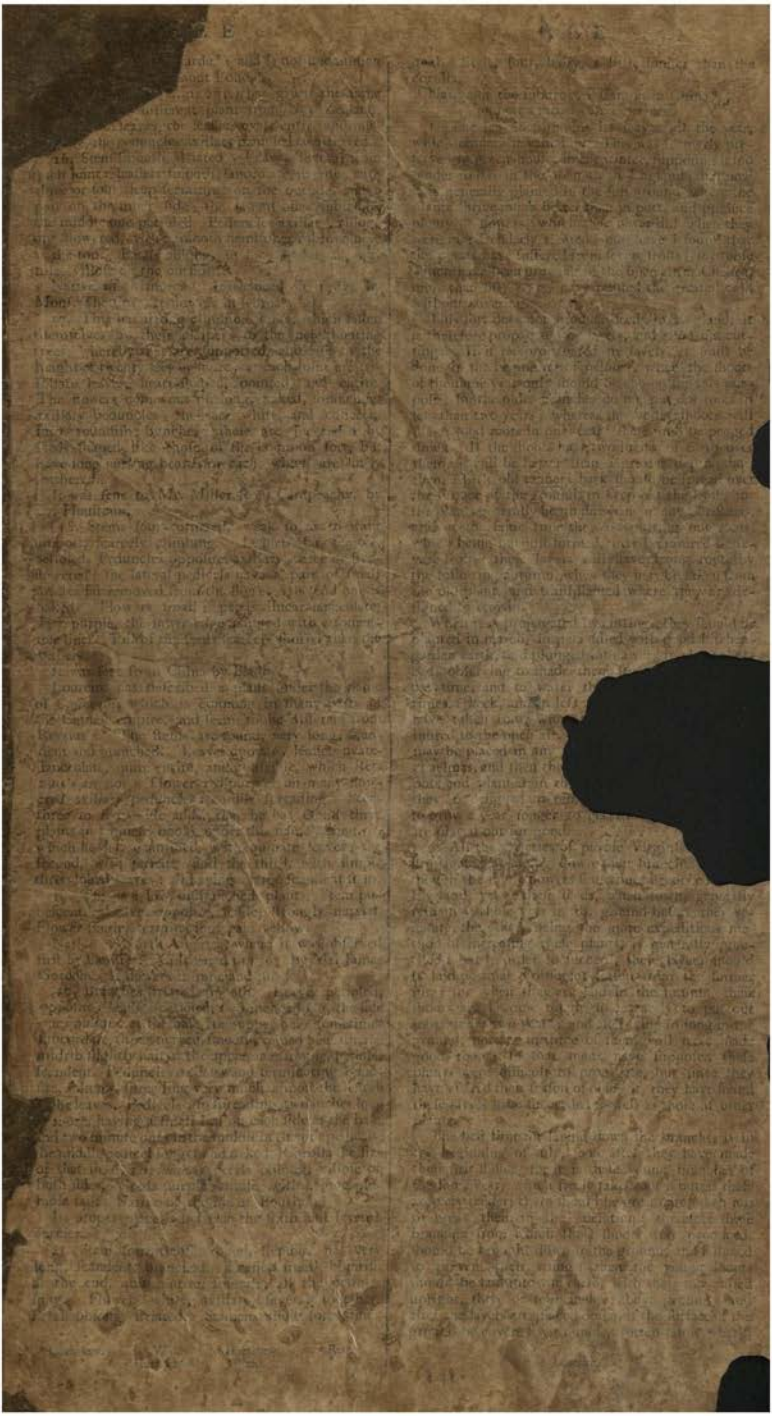
This plant, as well as most of the other species, is acrid, carrosive, and inflames the skin, whence the name *Flammula*. It is recommended by Baron Stoerck in invetcrate syphilitic diseases, in ulcers, cancers, and severe head-aches. It acts as a diuretic or diaphoretic. The character of *Cicuta* rests wholly on Stoerck's authority. He used an extract of the leaves; but he chiefly recommends an infusion of the fresh leaves, two or three drams to a pint of boiling water, four ounces to be taken three times a day, whilst the powdered leaves are applied as an escharotic to the ulcers. It may be used also for raising blisters, where cantharides cannot be obtained.

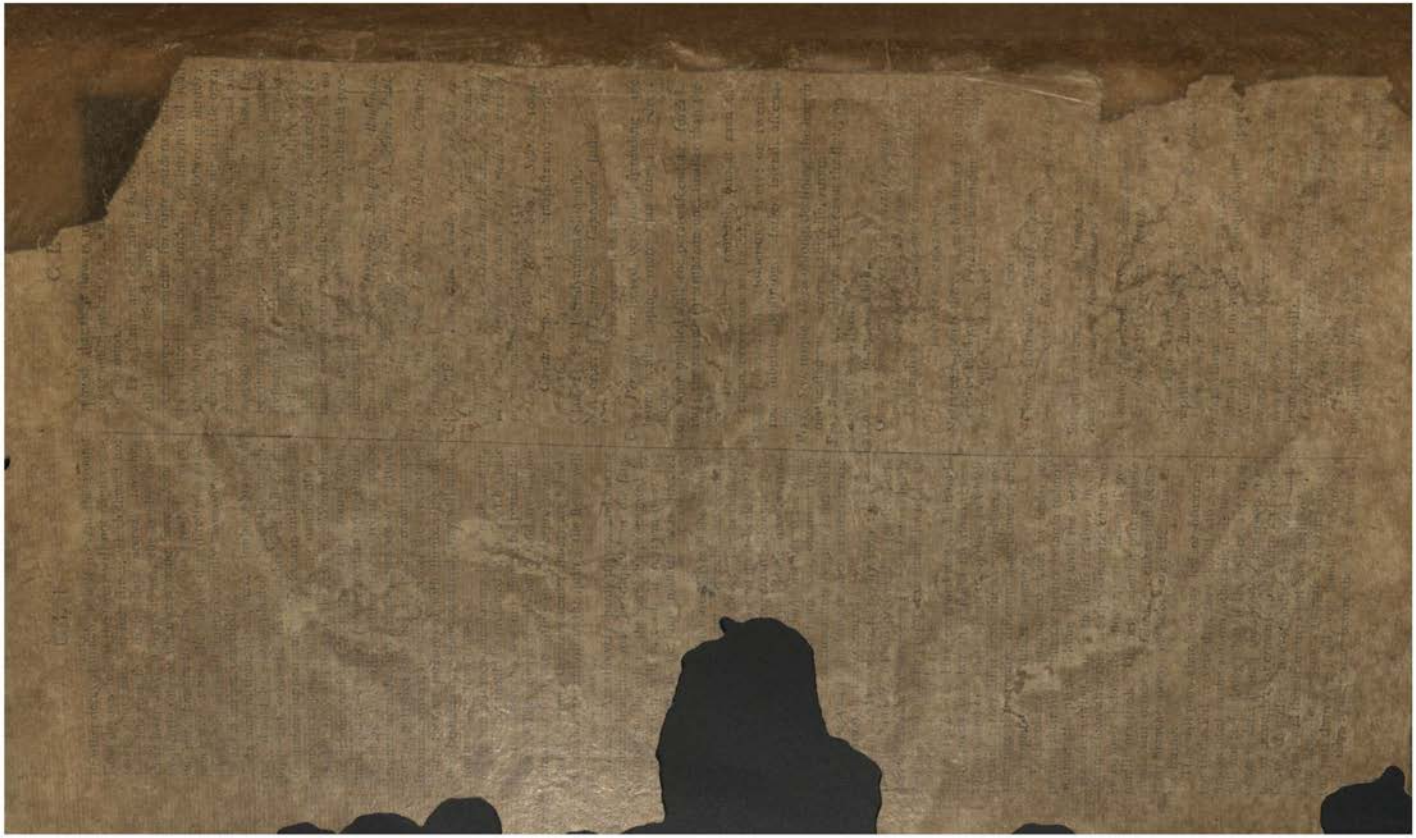
17. Perennial. Stems several, annual, a foot and half high or more, striated, erect, a little [illegible], somewhat pubescent at top, terminated by a nodding flower, and sometimes branched in the upper axils. Leaves opposite, ovate, sessile, quite entire, nerved, veined, acute, smooth, except about the edge and on the dorsal nerves, which are slightly villose. Scopoli remarks, that the two upper leaves, before the corolla is unfolded, are erect, keeled, and touching each other resemble an oblong bladder. Peduncles erect, pubescent, sustaining one elegant flower, but void of scent; petals large, lanceolate, blue, nerved, acute, waved, thick, spreading very much. Filaments very pale yellow, villose all over, and twice as long as the petals. Seeds roundish, compressed, somewhat villose, ending in a long plumose tail.

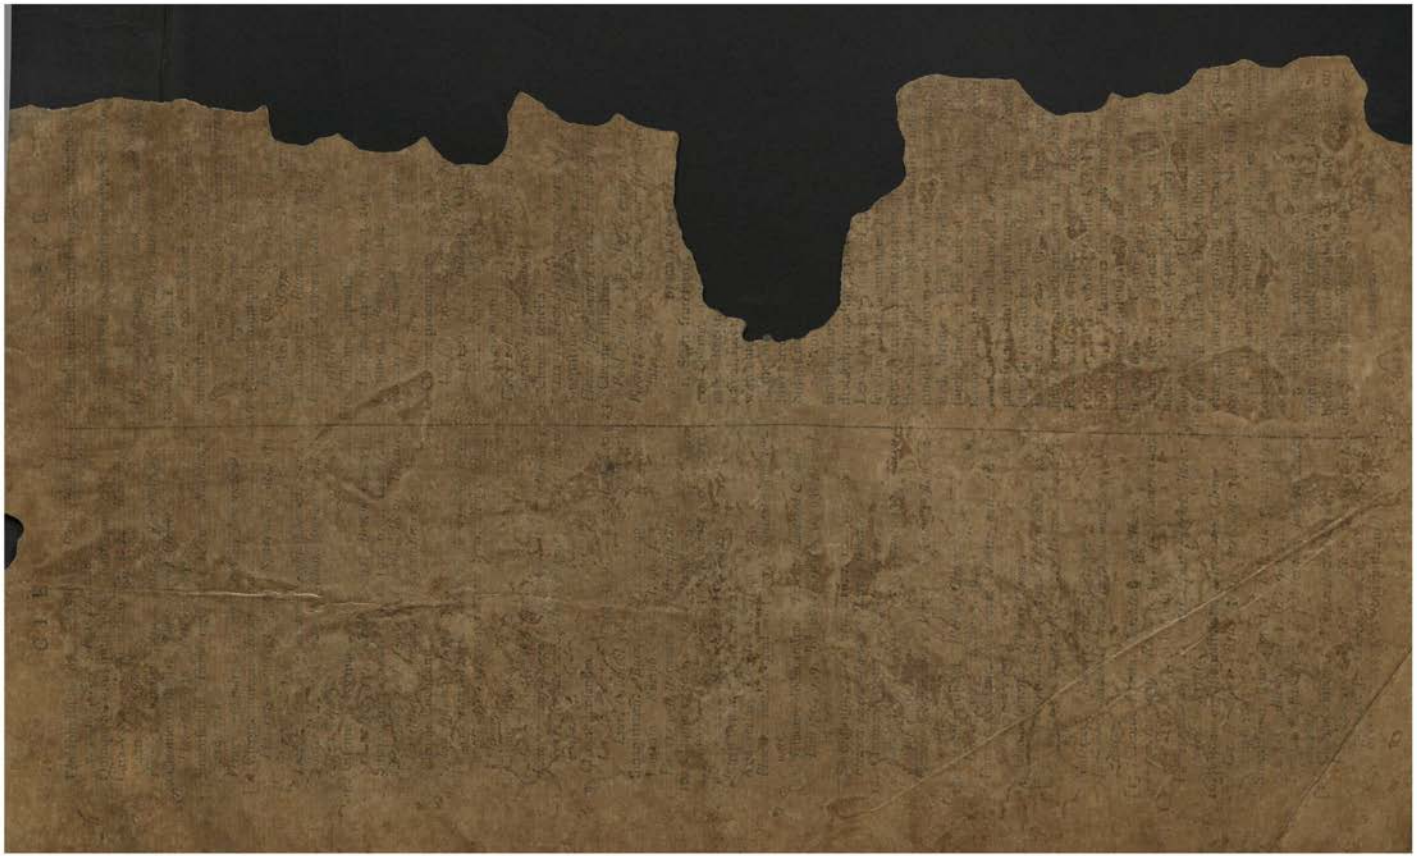
Native of Germany, Austria, Carniola, Hungary. It flowers in July, or from June to August. It was col-

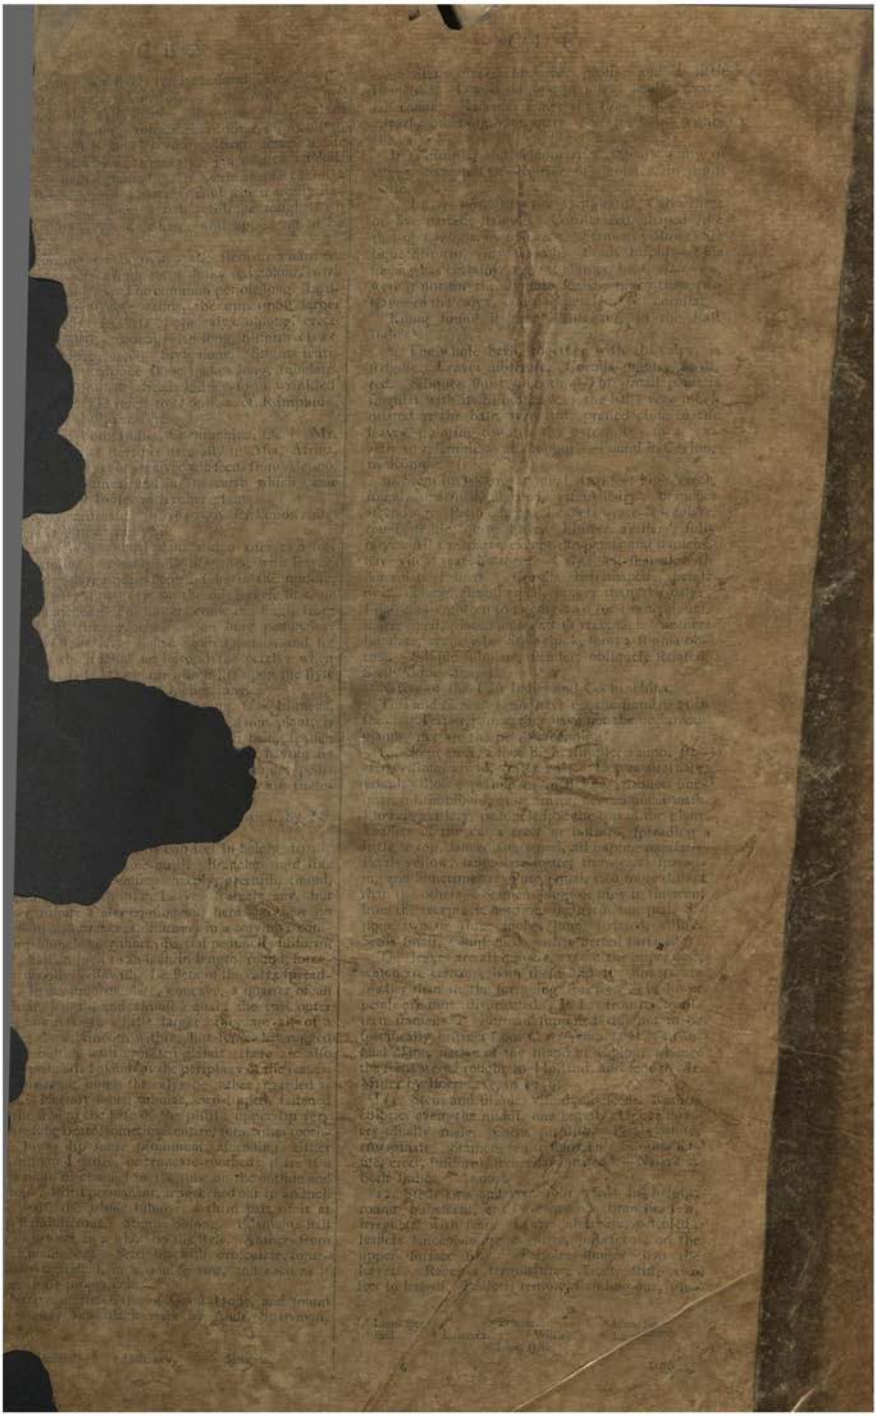
¹ Crantz. ² Miller. ³ Hort. Kew. ⁴ Linn. spec. ⁵ Jacquin. ⁶ Hort. Kew. ⁷ Jacquin.

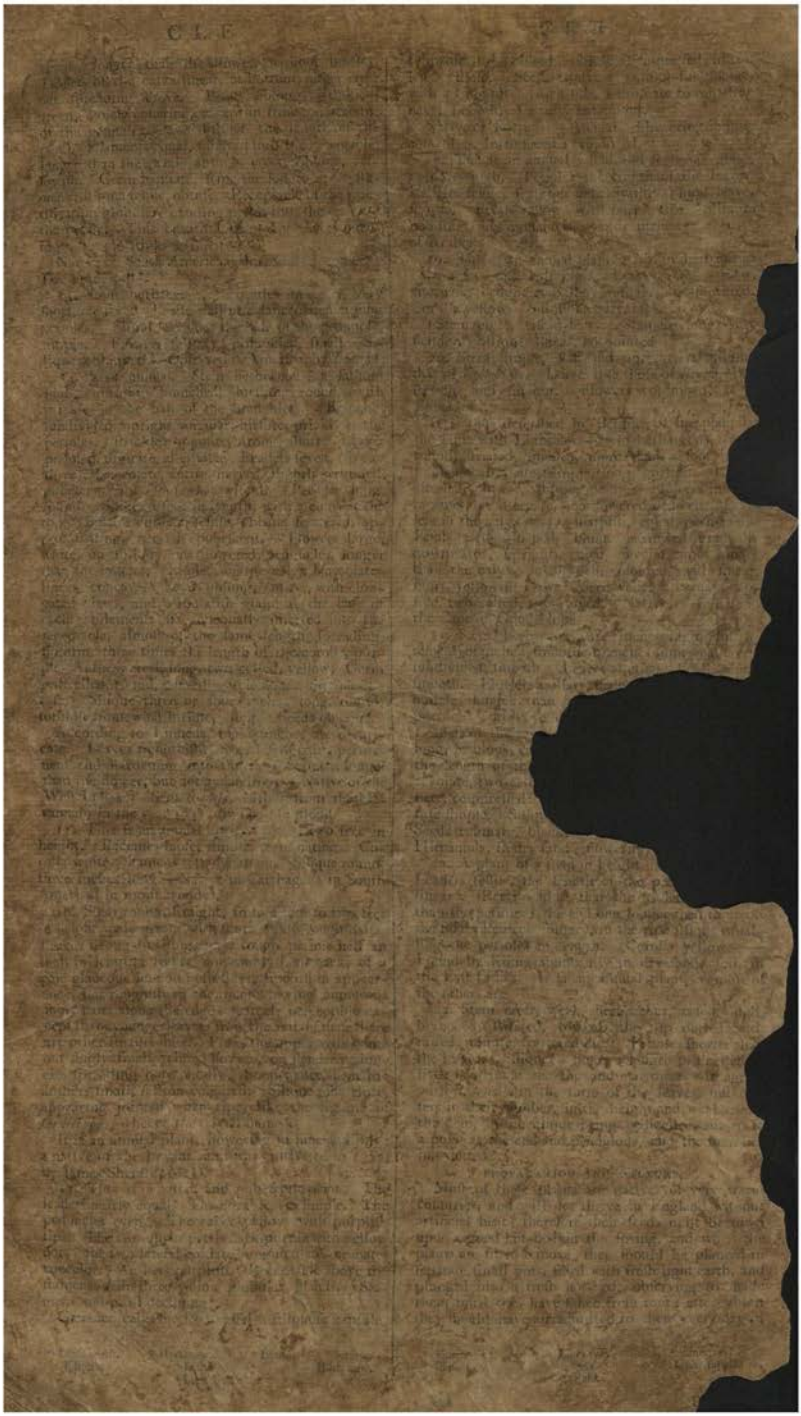
[illegible] quated

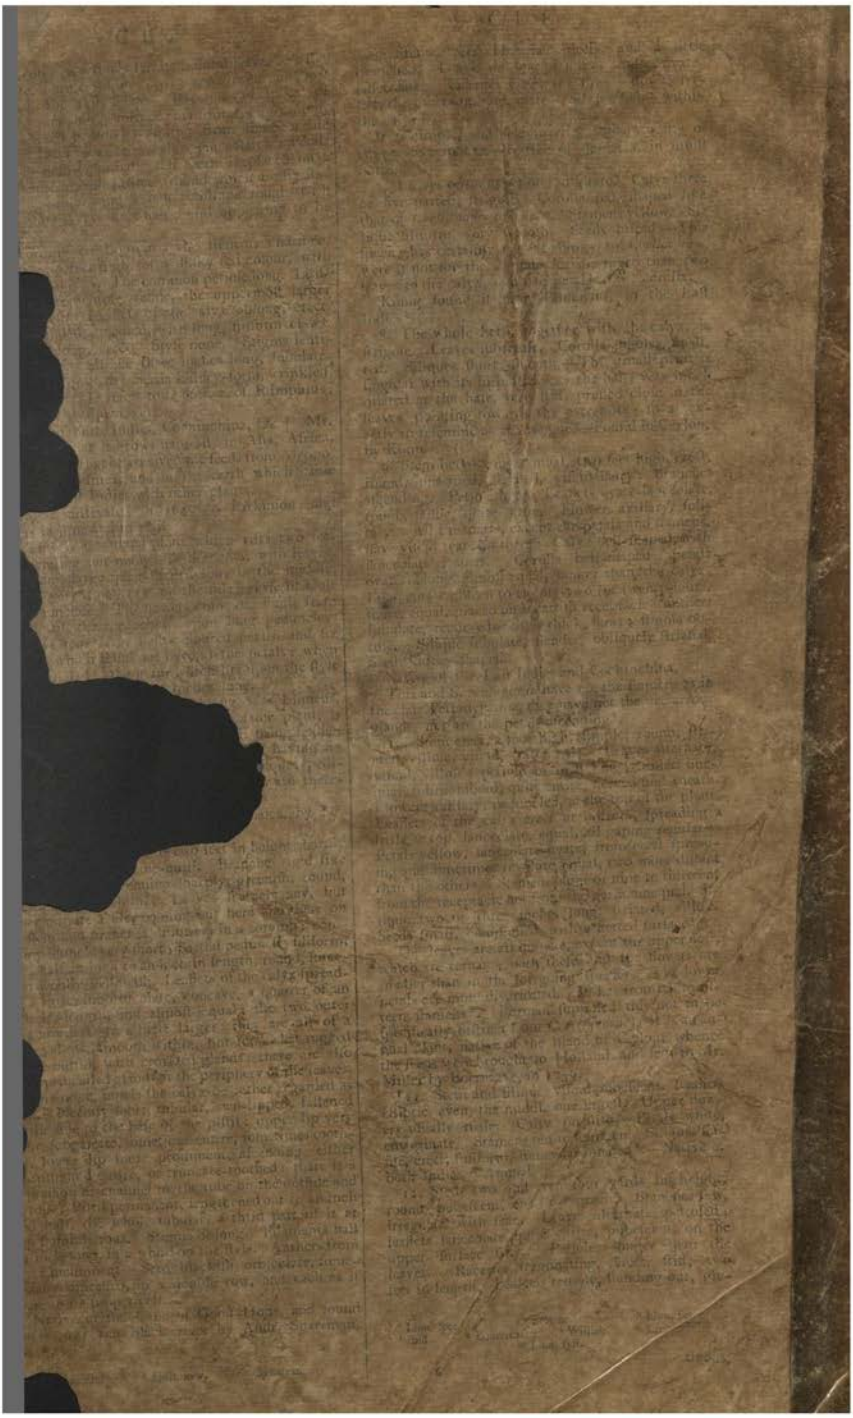


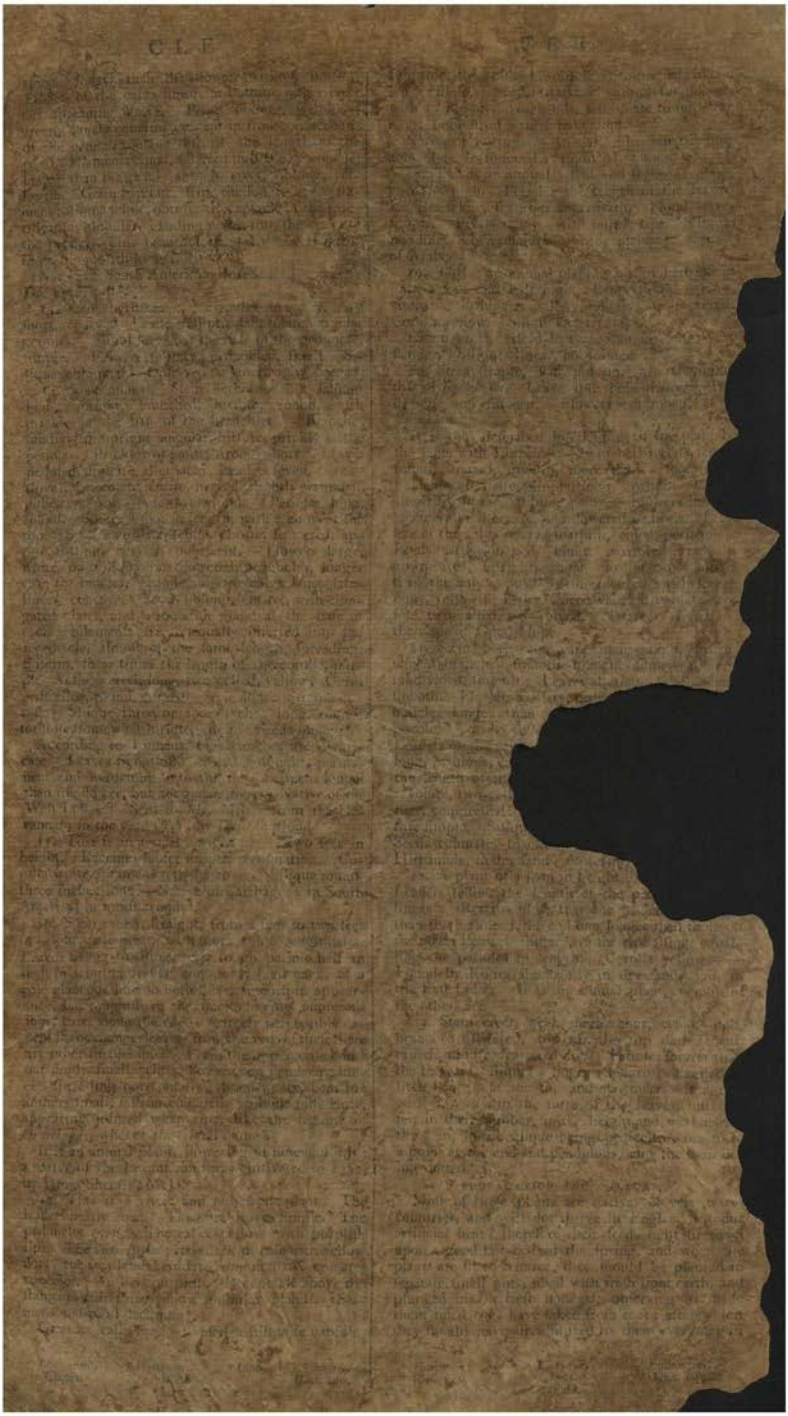


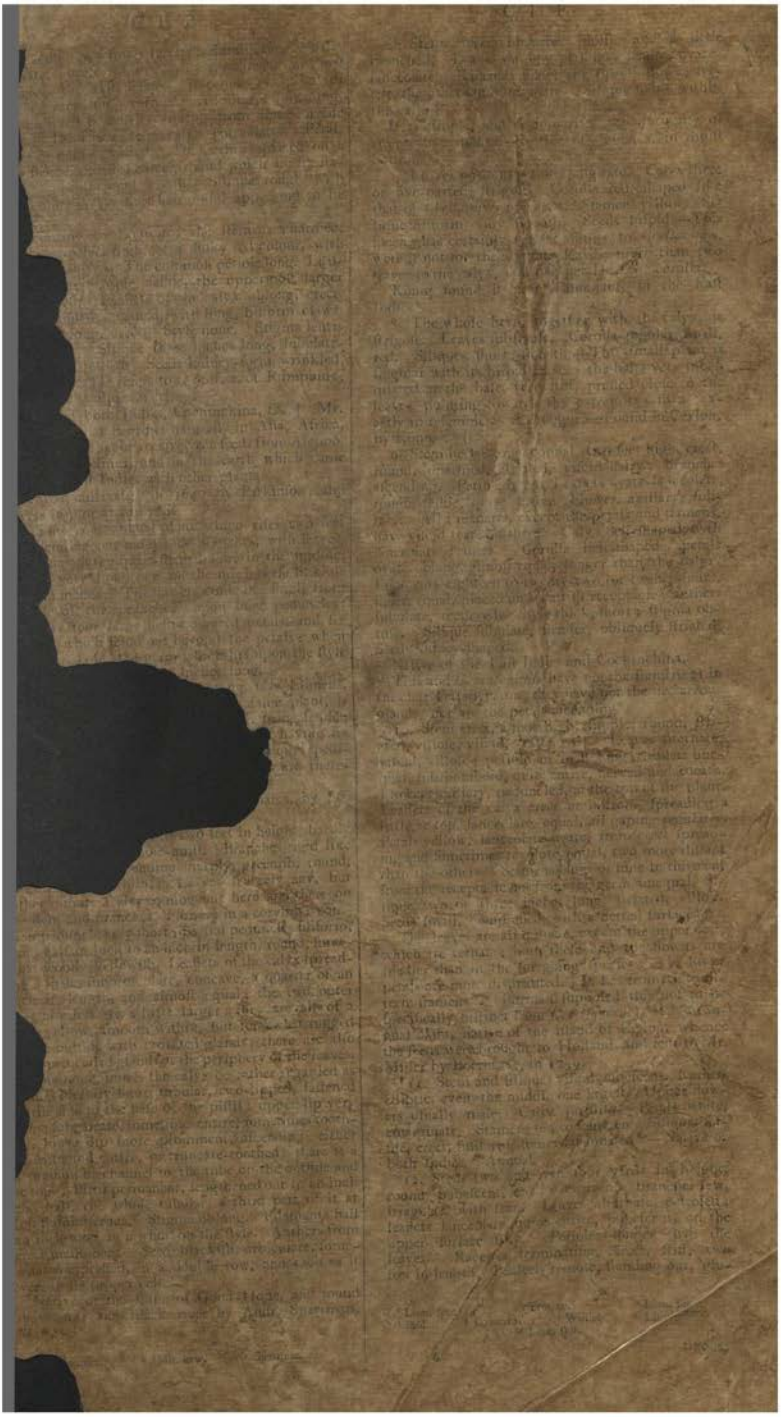


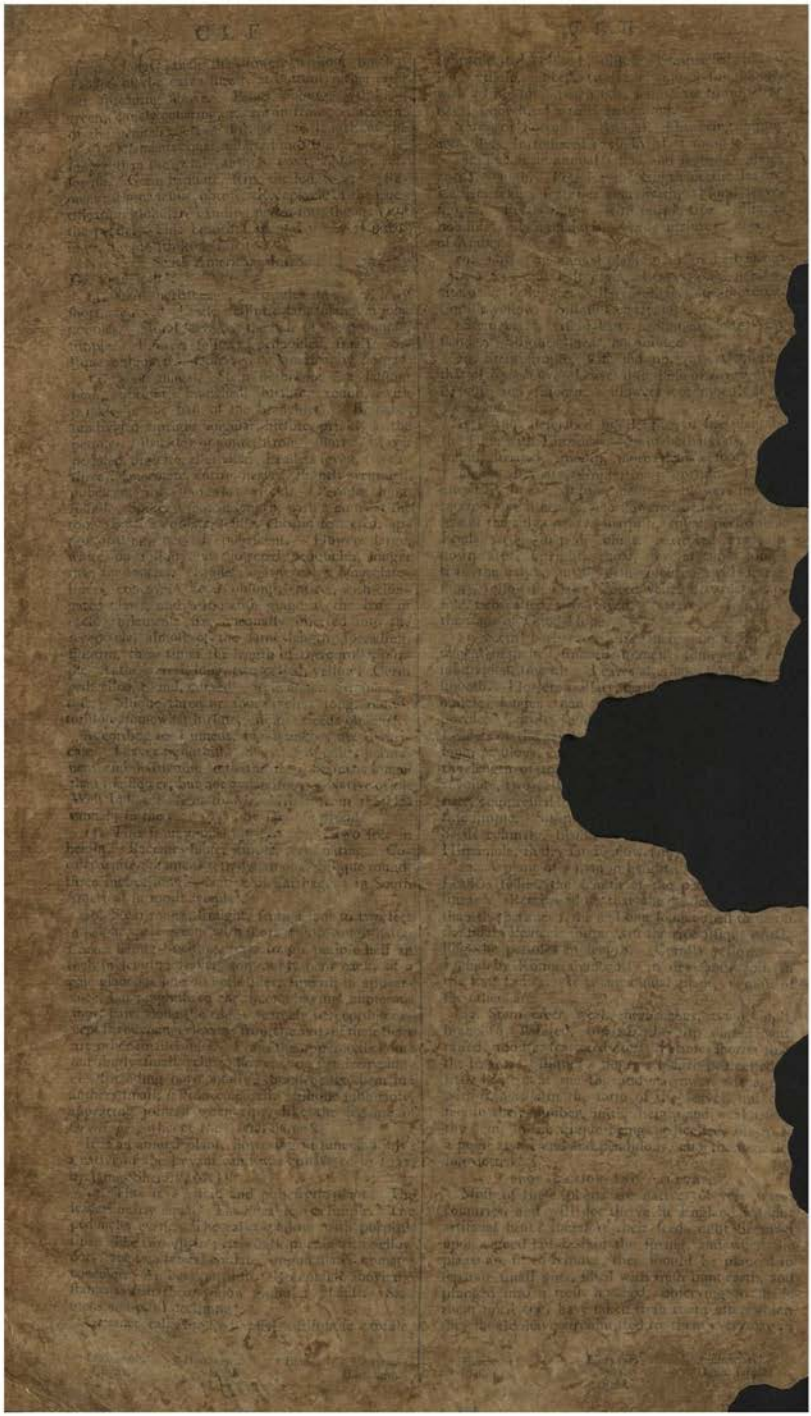


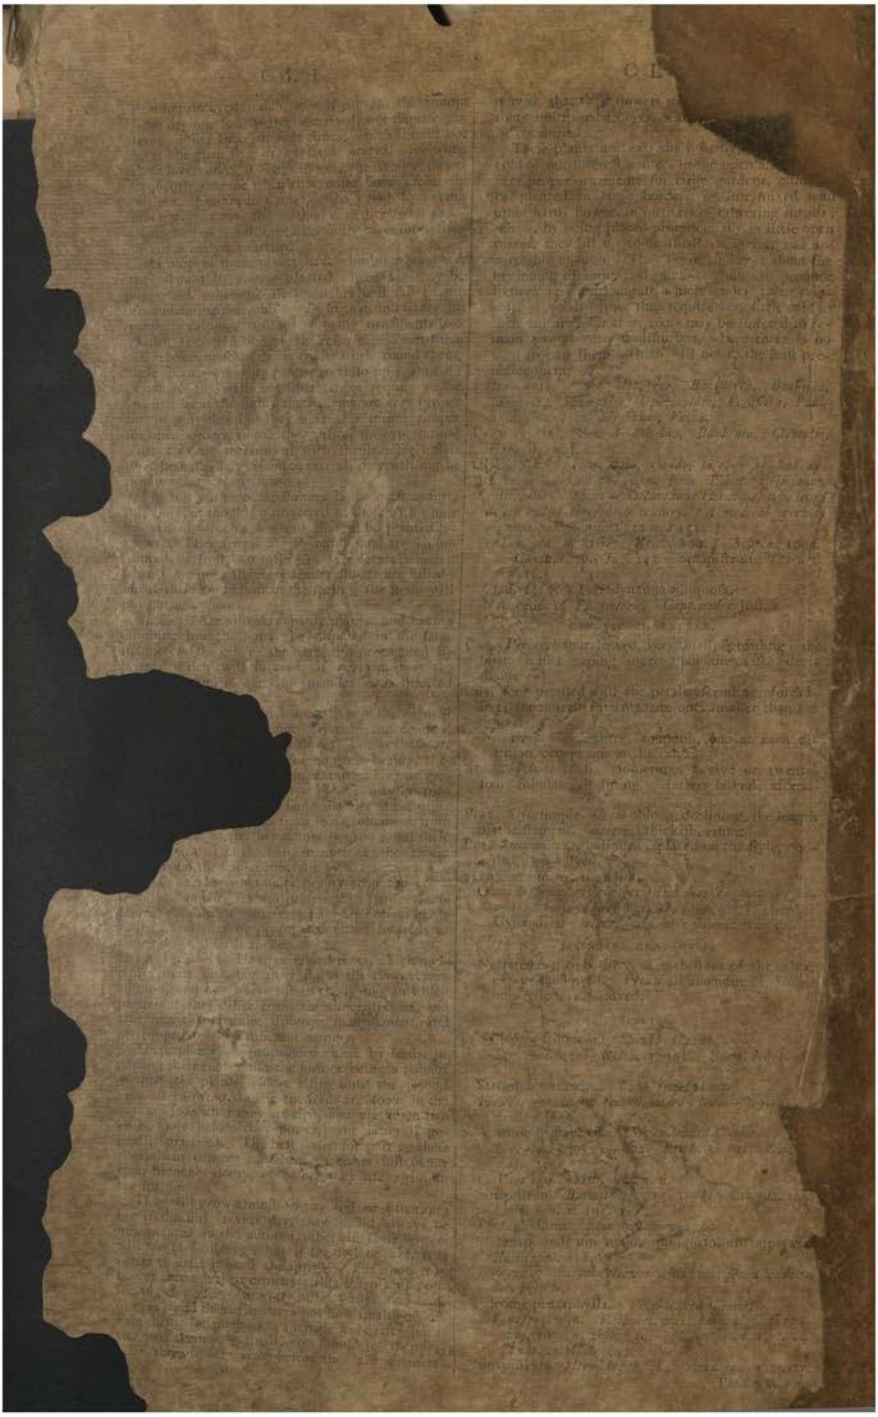


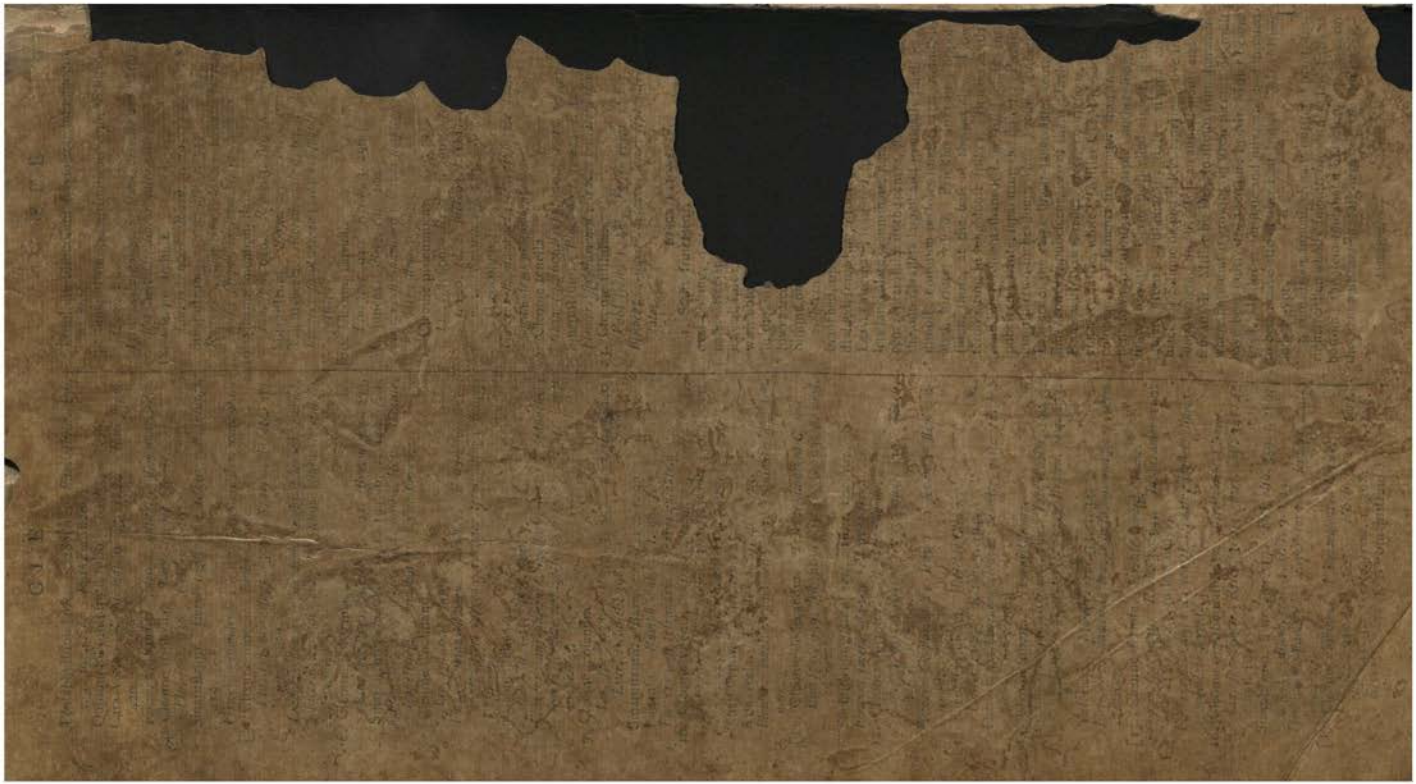












pitals yellowish white. The petioles swift about and serve as tendrils to elevate the plant. The female flowers have stamens, but the anthers are deficient of pollen.

Leaving aliens that the flowers are hermaphrodites, and that the seeds are six in number, of an ovate-oblong shape, with a straight hairy tail, about the same length with the stamens.

Native of North America, also of Japan and Cochinchina. Cultivated in 1760, by Mr. James Gordon. It flowers from June to August.

3. Stem striated, purple, smooth. Leaves opposite, petioled, ternate-ternate. Leaflets petioled, pinnatifide, ovate, entire or seldom gashed, villose, the middle one larger. Petioles foliate at the base, semicylindric, spreading out horizontally. Flowers axillary, pedunculed, nodding. Peduncles villose, one-flowered, longer than the leaves. Corolla large, hand-some, spreading; petals acuminate, yellowish. Stamens numerous, purplish. This differs from *C. viticella* in having decompound leaves, acute leaflets, and ovate [illegible]. Native of Japan.

Introduced about 1776, by John Fothergill, M.D. Flowers in the middle part of the year.

4. Stem flexuose striated purple villose. Leaves [illegible] from each joint, petioled. Leaflets on short petioles, acuminate, equally serrate from the middle to the end, ternate villose, the middle one larger. Petioles capillary, axillary. Flowers from the joints, pedunculed, solitary, purple. Peduncles one-flowered, the length of the leaflets. This differs from *C. virginiana* in having the leaflets not cordate, but drawn to a point towards both ends, the flowers cylindric, not ovate and [illegible]. Native of Japan.

5. This has slender tough climbing stalks, rising to the height of ten or twelve feet. Leaves exfoliate, growing out on each side the stalk; the leaflets are lanceolate, ovate and entire, having three or five longitudinal [illegible]. The peduncles are produced at the [illegible] of the petioles, one on each side, [illegible] horizontally, extending [illegible] divide and branch [illegible] pairs of small four-[illegible] which divides again [illegible] a single flower [illegible] four or five inches [illegible] top, so that they [illegible]s, these are white, [illegible] petals which are re-[illegible]urns all stand erect.

[illegible] about eighty seeds disposed in a heady [illegible] three-cornered and compressed, with [illegible] fringed with many white hairs.

Native of the West Indies, and also of Cochinchina, climbing very high without tendrils. It was sent to Mr. Miller from Jamaica, by Dr. Houstoun.

11. This shrub climbs as high as twenty feet by means of the swelled petioles. The younger stems are slightly furrowed, flexible and purple: the old ones are the thickness of the finger, deeply grooved, and of a whitish colour. Leaves opposite, spreading, on long petioles; they consist of two pairs of leaflets with an odd one, leaflets ovate, subacuminate, sometimes [illegible] ternate, serrate, or lobed, of a yellowish green colour, some what shining, veined on the under side. Flowers in axillary racemes, conjugate, leafy, dividing [illegible] into three, then into two smaller branches: sweet-scented. Petals four, cross-shaped, (sometimes five, [illegible] enterminate, spreading, a little reflexed back) [illegible] on the upper side of a pale sulphur colour, [illegible] greenish. Filaments the length of the corolla, upright, antners oblong, whitish. Seeds about twenty, covered with a membranaceous tube [illegible] coat, with whitish hairs scattered over it, and ending in a very long plumose tail; when the coat, which does not open of itself, is taken off, the seed appears to be elliptic, slightly lens-shaped, and of a pale yellow colour.

8. This in its appearance is very like the common [illegible]

sort, but the leaves are broader, and grow by threes on the same foot-stalk, whereas in that there are five or seven leaflets on each leaf. The flowers appear at the same time, but the seeds do not ripen in England, unless the season be very warm. There is little beauty in this sort. It is a native of North America.

[12. This is rather creeping than climbing. It is lower and more tender than the foregoing; leaves smaller, with five and seven pinnæ, or three-lobed, or three-leaved; leaflets ovate-lanceolate, with few gashes, and one or two teeths. Peduncles commonly, branching. Stipules numerous, setaceous. Petals lanceolate, white, marked with fibres, burning! Native South of France, Italy, the Crimea, &c. It flowers from July to October. Cultivated 1597, by Gerarde.]

13. Perennial. Leaves opposite, leaflets usually five pairs, ternate, linear, [illegible] rigid, subsessile, entire, undivided, but sometimes lobed or trifid. Flowers as in the next species. Magnol and Ray determine it to be a variety of *C. Flammula*, but J. Bauhin, Tournefort, &c. should rather suppose it to be a variety of *C. recta*, changed by the soil.—Near Montpellier, Nice and Venice.

14. Perennial. Stems herbaceous, annual, round, scarcely branched, from three to five feet high, erect, ending in a panicle at top. Leaves opposite, pinnate; leaflets from two to four pairs, with an odd one at the end, petioled, lanceolate or ovate, acute, the upper surface smooth and green, the lower somewhat villose and glaucous; they are entire, seldom two-lobed. Stipules minute at the division of the peduncle. Petals white, oblong, four in number, (sometimes five) obtuse, somewhat villose, a little longer than the stamens. Seeds few (from one to three or four, seldom more), dark brown, smooth, orbicular, much compressed; with a long, yellowish, plumose tail.

Linnæus remarks, that the umbels of flowers are upright and full.]

The flowers come out in June, and the seeds ripen in September.

[Native of France, Switzerland, Silesia, Austria, Carniola, Hungary, Tartary. Cultivated in 1597, by Gerarde.]

2. The variety which Mr. Miller makes a species, under the name of *C. Flammula*, differs only in having but two or three pairs of leaflets, which are narrower and stand further asunder, slighter stalks, and larger flowers.

[This plant, as well as most of the other species, is acrid, corrosive, and inflames the skin, whence the name *Flammula*. It is recommended by Baron Stoerck in inveterate syphilitic diseases, in ulcers, cancers, and severe head-achs. It acts as a diuretic or diaphoretic. The character of *Cinaria* rests wholly on Stoerck's authority. He used an extract of the leaves; but he chiefly recommends an infusion of the fresh leaves, two or three drams to a pint of boiling water, four ounces to be taken three times a day, whilst the powdered leaves are applied as an escharotic to the ulcers. It may be used also for raising blisters, where cantharides cannot be obtained.

15. Perennial. Stems several, annual, a foot and half high or more, striated, erect, a little villous, somewhat pubescent at top, terminated by a nodding flower, and sometimes branched in the upper axils. Leaves opposite, ovate, sessile, quite entire, nerved, veined, acute, smooth, except about the edge and on the dorsal nerves, which are slightly villose. Scopoli remarks, that the two upper leaves, before the corolla is unfolded, are erect, keeled, and touching each other resemble an oblong bladder. Peduncles erect, pubescent, sustaining one elegant flower, but void of scent: petals larger, lanceolate, blue, nerved, waved, toothed, spreading very much. Filaments very pale yellow, villose all over, and twice as long as the petals. Seeds roundish, compressed, somewhat villose, ending in a long plumose tail.

Native of Germany, Austria, Carniola, Hungary. It flowers in July, or from [illegible] to August, was cul-

Generic characters.

Calyx. Perianth one-leafed, five-parted, bell-shaped, permanent, ovate, acute, broader than the tube of the corolla, reticulated.

Corolla. One-petalled, irregular, ringent. Tube slender, cylindrical, much longer than the calyx, inclining. Border divided into five unequal segments, the three upper ones shorter, the two lower ones longer, spreading.

Stamens. Filaments four, slender, much longer than the corolla, spreading, the upper figure of the corolla, two of them shorter. Anthers incumbent.

Pistil. Germ roundish. Style filiform, length and situation of the stamens. Stigma simple, bifid.

Pericarp. Drupe (Berry) roundish, placed on a large calyx. Berry one-celled, four-seeded, often splitting into four parts.

Seeds. Seed one in each berry, roundish, as one-celled, convex and wrinkled on one side, angular and hollow on the other, fastened at the same place. Gærtn.

Specific characters.

1. Clerodendrum infortunatum.

Calyx five-cleft, bell-shaped. Corolla with a filiform tube, and a funnel-shaped, five-parted, equal border. Stem very nearly quinary. Berries two-celled, four-seeded, often splitting into four parts when ripe. Gærtn.

Leaves wedge-form ſerrate at the end.

DESCRIPTIONS, *&c.*

The Cliffortias are ſhrubs from the Cape of Good Hope. Leaves ſimple or ternate, ſheathing at the baſe. Flowers axillary, ſubſeſſile.

1. This is an erect ſhrub, three feet high, little branching. Branches ſimple, ſubpubeſcent. Leaves alternate, ſubpetioled, obtuſe, by no means ſtiff. Stipules under the leaf, membranaceous, ſemibifid, acute, withering. Flowers from the axils of the leaves. Calyx three-parted. The male flowers only have been obſerved; theſe agree with the other ſpecies of Cliffortia, though the habit is different, and rather reſembles that of Mint[a].

This, and moſt of the other new ſpecies of the Supplement, were found at the Cape of Good Hope by Thunberg.

2. A ſhrub, with alternate declining branches, clothed with truncated membranes and ſtipules. Leaves alternate, ſheathing very ſhortly at the baſe, roundiſh, having ſeven or nine teeth terminated with ſpines, ſpreading, recurved at the end, flat, cartilaginous about the edge, nerved, ſmooth, biennial, horizontally deciduous, leaving a reddiſh permanent ſheath. Stipules at the baſe of the leaf in front, above the ſheath, acuminate-thorny, ſpreading, permanent. Flowers lateral, axillary, ſeſſile, ſolitary, green. Filaments white, anthers yellow[b].]

Stem weak, four or five feet high. Leaves grayiſh. Before the calyx opens, it forms a bud, in ſhape and ſize like thoſe of the Caper. The flowers appear in june, july, and auguſt; but the leaves continue in verdure through the year. The plants in the European gardens, both of this and the following ſort, are all male. [Cultivated 1714, in Chelſea garden.

3. Branches alternate, frequent, aſcending, below aſh-coloured, ſmooth, above brown, tomentoſe: branchlets alternate, very frequent, ſhort, covered with lanceolate, acuminate, imbricated [illegible] other reſpects naked, except at [illegible] where they are leafy. Leaves ovate-lanceo[illegible]th a ſpine at the end, ſomewhat gaſhed, the [illegible] ſurface ſmooth, even and ſhining, the lower ſix-nerved and villoſe; they are ſeſſile and approximating. Spikes of flowers roundiſh, at the ends of the branchlets, intrenched in leaves. Bracles ſmaller than the leaves, involving each flower, trifid, hirſute on the outſide, ſpiny, with a ſharp, membranaceous, hairy leaflet near the baſe on each ſide. The female flowers have a double perianth: the lower two-leaved, inferior; leaflets linear, obtuſe, broader at the baſe, concave, claſping, hairy, tender, longer than the germ: the upper three-leaved, ſuperior; leaflets ovate, acute, mucronate-hairy, green, ſmooth, reflex-ſpreading, the length of the germ. Germ ovate, obtuſe, attenuated at the baſe, ſubgibboſe, ſtreaked and angular[c].

Introduced in 1786, by Mr. Francis Maſſon[d].

4. Stems like thoſe of Knot-graſs, filiform, uſually proſtrate, even, branching. Branches ſhort, ferruginous, herbaceous. Leaves alternate, ſubpetioled, ſtriated, acute, naked, ſerrate; the ſerratures ſetaceous, unarmed. Stipules two-parted, ferruginous, ſcarioſe. Flowers axillary, ſeſſile, trifid.—The female has not been obſerved.—Found at the Cape by Sparrmann[e].

5. Stems many together, two feet high, ſcarcely branching, ſtriated, covered with leaves, which are approximating, erect, convolute, ſmooth, ſtriated, acute. Petioles connected with the leaves by a joint; the edges elongated into ſubulate, erect diviſions[f].

6. This is a ſmaller ſhrub than the ſecond and third ſorts. Branches naked, upright, leſs divided, alternate, gray, pubeſcent, round. Leaves numerous, imbricate-faſcicled, lanceolate-linear, quite entire and reflex at the edge, acuminate, ſeſſile. It differs from *C. ruſcifolia*, in having leaves only one fourth of the ſize, with a ſingle nerve, hairy and

[a] Linn. ſuppl. [b] Linn. mant. [c] Berg. cap. [d] Hort. kew. [e] Linn. ſuppl. [f] Ibid.

ſeſſile:

ſeſſile; whereas in that they are ſmooth and toothed at the baſe, with three nerves at the back [a].

7. Of this we have no deſcription. It was found at the Cape, with many of the others, by Thunberg.

8. An erect ſhrub, rather large. Leaves alternate, ſeſſile, conjugate, very finely crenulate, ſmooth. Flowers axillary, ſolitary, trifid.

9. Leaves converging, and guarding the flowers in the cavity which they form, like *Hedyſarum pulchellum*, beautifully adorned on the outſide with radiating nerves [b].

10. Stems ſlender, woody, procumbent, ſilky with hairs, and ſending out ſlender branches on every ſide. Leaves ſeſſile, hairy, the middle leaflet much broader than the two ſide ones, which are lanceolate. Flowers axillary, on very ſhort peduncles, ſhaped like thoſe of the ſecond, but ſmaller; they appear in july and auguſt. We have only male plants in the Engliſh gardens.

[Cultivated by Mr. Miller before 1759.

11. Stem ſhrubby, ſarmentoſe, filiform, four feet high, irregular: branches alternate, ſhort, ſimple, round, pubeſcent. Leaves alternate, ſubſeſſile, ſubequal, very narrow, unarmed, hoary-pubeſcent. Petiole very ſhort, ſtipular, membranaceous, dilated, emarginate, naked. Flowers lateral, axillary, ſeſſile, ſolitary, white.—The female has not been obſerved [c].

12. A ſhrub with round branches, ſparingly branched. Stipules (at firſt petioles) ſheathing, ſcariole, ſubovate, having two teeth, ſmooth, permanent. Leaves ſeſſile, carinated, on a very ſhort, ſheathing petiole. The fructification not having been obſerved, we can only conjecture the genus from the ſtructure. The ſtrobiles are galls, not fruits [d]. Juſſieu doubts whether this ſpecies with its ſtrobile-ſhaped galls, and ſo different in habit, be really a Cliffortia.

13. An erect lowly ſhrub, with diſtich branches. [illegible] ſeſſile, obovate, nerveleſs, very obtuſe, quite [illegible] like thoſe of *Peplis* (Purſlane), ſmall. [illegible] in the axils of the leaves, ſeſſile, not longer [illegible] leaves. The leaves are often in pairs.

14. A ſhrub, with ſmall, ovate-lanceolate, hairy leaves, very different from the other Cliffortias.

15. A ſhrub [illegible]mbling Juniper, erect, three feet in height, branching very much. Leaves faſcicled, acerote (like thoſe of Juniper) linear, channelled, mucronate, ſubferrate, on a broadiſh petiole, ſo ſhort as ſcarcely to be obſervable. Flowers axillary, ſeſſile.—Obſerved at the Cape by Sparrmann.

16. A ſhrub, a foot in height, erect, branching, ſtrict. Leaves often three from each bud: leaflets ſharpiſh, incurved. It reſembles *C. farmentoſa* in the leaves, but they are ſmooth in this ſpecies.

17, 18. There is much ſimilitude between theſe and *C. filifolia* [e].

19. Native of the Cape, (with all the former) Mr. Fr. Maſſon. Introduced 1787. It flowers in april [f].]

PROPAGATION AND CULTURE.

2. This plant is eaſily propagated by cuttings, which may be planted in any of the ſummer months; if theſe are planted in ſmall pots filled with light earth, and plunged into a very moderate hot-bed, they will ſoon take root, provided they are ſcreened from the ſun, and duly watered; when they have taken root, they muſt be gradually inured to bear the open air, to which they ſhould be expoſed, to prevent their drawing up weak: therefore they ſhould be placed abroad till they have obtained ſome ſtrength, then they may be each tranſplanted into a ſeparate ſmall pot, and placed in the ſhade until they have taken freſh root; after which they may be placed with other of the hardy kinds of exotic plants in a ſheltered ſituation till october, when they ſhould be removed into the green-houſe, or placed under a common hot-bed frame, where they may be ſcreened from the hard froſt, but enjoy the free air at all times when the weather is mild.

When the plants advance in height, their ſtems and branches muſt be ſupported, otherwiſe they will trail upon the ground. In ſummer they muſt be placed in the open air, with Myrtles and other hardy green-houſe plants; and in winter the plants may be treated in the ſame manner as thoſe, but muſt have little water in winter. This plant has endured the cold of our ordinary winters, when planted near a ſouth-weſt wall without covering, but in ſevere winters it is always deſtroyed.

3. This is more tender; therefore it ſhould be placed in a warm green-houſe in winter, and during that ſeaſon ſtould have little water. In ſummer it may be expoſed to the open air in a ſheltered ſituation, but ſhould not remain abroad too late in autumn; for if there ſhould be much rain at that ſeaſon, it might endanger the plants. We have only the male plant in Europe, and it is difficult to propagate.

10. This requires the ſame management as the ſecond, and is equally hardy; but muſt not be over watereid in winter. As there are only male plants in Europe, it is only propagated by layers, and theſe are two years before they take root. The leaves continue green all the year, and being ſingularly ſhaped, they make a variety in the green-houſe during the winter ſeaſon.

[The other ſorts, coming from the ſame country, and being ſhrubs of the ſame nature with theſe, whenever they are introduced among us, will be propagated in the ſame manner, and require the ſame treatment.

CLIMBER. See *Clematis*.

CLINOPODIUM. (Κλινοποδιον, *Dioſcor. From* κλινη *and* πους, ποδος, *a bed, bed's-foot.—The flowers growing in whorls, one above another, like the old-faſhioned turned feet of beds.*)

Lin. gen. n. 725. *Reich.* 783. *Schreb.* 980. *Tournef.* 92. *Juſſ.* 115. *Rai meth.* 64.

Claſſ. 14. 1. Didynamia Gymnoſpermia.

Nat. order of *Verticillatæ*. *Labiatæ* Juſſ.

GENERIC CHARACTER.

CAL. *Involucre* many-briſtled, length of the perianth, placed beneath the whorl.

Perianth one-leafed, cylindric, very ſlightly incurved, with a two-lipped mouth; upper lip wider, trifid, acute, reflected: lower lip diviſed, ſlender, inflected.

COR. one-petalled, ringent; *Tube* ſhort, gradually widened into the throat; upper lip erect, concave, obtuſe, emarginate. Lower lip trifid, obtuſe; middle ſegment wider, emarginate.

STAM. *Filaments* four, under the upper lip, of which two are ſhorter than the others. *Anthers* roundiſh.

PIST. *Germ* four-parted. *Style* filiform, the ſame ſituation and length with the ſtamens. *Stigma* ſimple, acute, compreſſed.

PER. none. Calyx contracted round the neck, gibbous round the body, containing the ſeeds.

SEEDS four, ovate.

ESSENTIAL CHARACTER.

Involucre many-briſtled, under the whorl.

Leaves oblong, nerved, wrinkled, tomentose underneath, spike whorled, terminating.]

DESCRIPTIONS, *&c.*

1. Root perennial, fibrous, sending up several stiff square stalks a foot and half high, from which come out a few lateral branches towards the top. The flowers come out in round whorls; one of these terminates the stalk, and there is generally another which surrounds the stalk at the joint immediately below it. The whorls grow very close, and each peduncle sustains several flowers, which are usually purple, but sometimes white: they appear in june.

[The whole plant is hairy. Stems reddish. Leaves distant, ovate, sometimes cordate-ovate, or ovate-acuminate, serrate, or crenate, sometimes nearly entire, on short petioles. Forty flowers are found in one whorl; calyx very hirsute; colour of the corolla bright red; tube long; lower lip crenate.—It is fond of a calcareous soil.—The smell is slightly aromatic, and not unpleasant.]

β. Stems not more than half the height of the common sort, and dividing into many long side branches; leaves smaller and rougher; whorls produced half the length of the branches, whereas the common sort has rarely more than two; the bractes are also much longer. This flowers in june and july, and has a perennial root.

γ. Root perennial. Stems straight, hairy, almost round, joints four or five inches asunder, with two oblong leaves at each, hairy on their under side, on short foot-stalks; at the bottom of these a slender branch comes out on each side, half an inch long, having two or four small leaves shaped like the others. The flowers are produced in small whorls, standing thinly; they are white, and the bractes are longer than the calyxes. It flowers in august.

Both these were sent to Mr. Miller from Carolina by Dr. Dale.

δ. Root perennial. Stems a foot and half high. Leaves oval, with many transverse deep furrows, dark green, opposite, five or six inches asunder. There are commonly two or four side branches from the main stem, produced towards the bottom; and the whorls of flowers are produced at every joint towards the upper part of the stem, which are pretty large and hairy. The flowers are somewhat larger than those of the common sort, of a deeper colour, and stretch a little more out of the calyx; but the greatest difference between them is, that in this the leaves and whorls are placed at a greater distance; nor do the plants continue so long. It is a native of Egypt.

It flowers in june, a fortnight or three weeks before the common Field Basil, and the seeds ripen in september.

2. Root perennial. Stems about two feet high, putting out a few short side branches towards the upper part. Leaves oblong, oval, the size of those of Water Mint, opposite, sessile, soft to the touch, with a strong odour between that of Marjoram and Basil, the upper surface pale green, the under hoary and woolly; the edges are slightly indented. Whorls flat, smooth, generally three, the upper smaller and terminating, the lowest larger than the middle one. Flowers pale purple, the stamens standing out beyond the corolla; the bractes large, lanceolate, indented. Native of North America, where in some parts it is called Snake-weed, being looked upon as a remedy for the bite of the rattle-snake. In England it flowers in july. Mr. Miller frequently received the seeds from Pennsylvania and Carolina. [Sherard had them from Virginia and Maryland; and it was cultivated in the Eltham garden in 1732.]

3. Root perennial. Stems closely covered with brownish hairs, and between two and three feet high. Leaves very unequal in size, serrate, rough on their upper side, hairy on the under. Peduncles slender, hairy, about three inches long, sustaining small heads of flowers shaped like those of the Scabious; corolla white, smaller than that of the foregoing; bractes radiate. It flowers in september, but never ripens its seeds here. Native of Carolina, whence the seeds were sent to Mr. Miller by Dr. Dale. [It was cultivated in the Eltham garden, and before that, in the royal garden at Hampton Court, in 1690[a].

4. Jacquin makes this a distinct genus, under the name of *Hyptis*, from the inverted (*vulva*) form of the corolla. He thus describes it.

Stems suffruticose, two or three feet high; from these in the spring arise herbaceous stems, which are quadrangular, roughish, two feet high, branched. Leaves opposite, petioled, ovate, but with the base acute, veined, unequally serrate, acute, both sides appearing hairy with a magnifier, deep green; the lower ones wrinkled, the largest seven inches long. Peduncles solitary, quadrangular, slender, when full grown two or three inches long, bearing at the top numerous flowers collected into a close semiglobular head, supported at bottom by an involucre of many lanceolate leaflets. Calyx somewhat hispid. Corolla white, with a tinge of flesh-colour; tube somewhat hairy on the outside, but the back of the helmet more so; border spreading much, often reflex and inverted, upper lip trifid, lower (which is uppermost by the inversion of the corolla) semibifid. The whole plant is inodorous[b].

Native of Jamaica, Barbadoes, and St. Domingo. Cultivated in the Eltham garden in 1732.

5. Stem suffruticose, two feet and an half high, erect, quadrangular, four-furrowed, simple, villose. Leaves ovate-oblong, obtuse, slightly serrate, many-nerved. Flowers violet-coloured, in interrupted whorls, forming an oblong spike, with sharp, hirsute involucres. Calyx two-lipped, quite entire, unequal, very hairy. Upper lip of the corolla concave, equally trifid; lower reflected, quite entire, longer. Native of Cochinchina[c].]

PROPAGATION AND CULTURE.

These plants may be propagated by seeds, and also by parting their roots; the latter is generally practised in England, because the foreign sorts do not perfect their seeds here. The best time to transplant and part their roots is in autumn, that they may take root before winter. If these are planted in a dry soil, they are (except the third sort,) hardy enough to thrive in the open air in England, and require no other care but to keep them clean from weeds, and every other year they may be transplanted and parted. The third sort must be planted in pots, and in winter sheltered under a frame, where the plants may enjoy the free air in mild weather, but screened from frost, otherwise they will not live in this country.

Leaves ternate; raceme erect; flowers pendulous.]

DESCRIPTIONS, &c.

1. This riſes with a twining herbaceous ſtalk to the height of four or five feet, in the ſame manner as the Kidney-bean, and requires the like ſupport; for in the places where it grows naturally, it twiſts itſelf about the neighbouring plants: the leaves are winged, compoſed of two or three pair of leaflets, terminated by an odd one; theſe are of a beautiful green, and are placed alternate on the ſtalks; from the appendages of the leaves come out the pedunculs; each of theſe is encompaſſed by two very fine leaves about the middle, where they are bent, ſuſtaining a very large, gaping, beautiful flower, whoſe bottom part ſeems as if growing to the top.

The flowers have a green membranaceous calyx; the corolla is of a blue colour, and ſtains paper, like Indigo, but as a dye it is not permanent. It is a native of the Eaſt Indies and Cochinchina, but the ſeeds were firſt brought to Europe from Ternate, one of the Molucca iſlands, and this induced Tournefort to give the name of Ternatea to this genus. There is a variety with white flowers, and another with blue flowers, which are very double.

[This production of double flowers is a ſingularity in the leguminous claſs of plants.

The legume is narrow, elongated, a finger's length and more, lenticular-compreſſed, without knots or riſings, ſubpubeſcent, pale, terminated by the longiſh, ſubulate ſtyle, many-celled, two-valved: partitions thin. Seeds ſolitary, ſeven to twelve, ovate-kidney-form, cut off at one end, compreſſed a little, ſomewhat gibboſe on both ſides, ſmooth, cheſtnut-brown [a].—Cultivated 1739, by Mr. Miller [b]. Breynius received the ſeeds from the Eaſt Indies in 1667.]

2. This has a twining ſtem like the foregoing, which riſes five or ſix feet high, having at each joint one ternate leaf on a long petiole. The flowers come out ſingly from the axils on long peduncles, encompaſſed about the middle with two ſmall oval leaves; the flowers are very large, the ſtandard being much broader than that of the firſt ſort, and the two wings are larger; the flowers are of a fine blue colour, and make a fine appearance. They appear in July, and in warm ſeaſons the ſeeds will ripen in autumn, ſoon after which the plants decay. Native of Braſil.

There is one with a double flower of this ſort, which I raiſed in the Chelſea garden ſome years paſt, from ſeeds ſent me from India; but the plants did not produce ſeeds here, and being annual, the ſort was loſt. [The leaves of the figure in hort. malab. are obovate.

3. Stem herbaceous, filiform, ſubdivided, ſcandent and twining, round, ſtriated, pubeſcent. Petioles of the leaves longiſh, pubeſcent. Leaflets oblong, acuminate, with a blunt tip, entire, nerved, ſmooth, ſometimes pubeſcent, on ſhort petiolules. Peduncles longer than the petioles, erect, angular, ſtriated, hirſute, bearing three or four whitiſh flowers on pedicels. Perianth double; outer two-leaved; leaflets ovate-acute, concave, keeled, pubeſcent; inner tubular, two-lipped, the two upper teeth ſhorter, approximating, the three lower longer, acute, the middle one three times as long as the others. Corolla reſupinate: ſtandard blue, with oblique purple ſtreaks, at the back part duſky, and tomentoſe. Seeds ſmooth, and of a gray colour [c].

The two membranaceous bractes are ſmaller and leſs conſpicuous in this ſpecies. Leaflets in appearance ſmooth, but roughiſh to the touch. Two flowers uſually come out together. Legumes leſs ſwelling than in the firſt ſpecies. Seeds brown, with duſky red ſpots [d].

This ſpecies being tender, and flowering here with difficulty, the flowers frequently come out ſingly in our ſtoves; which accounts for the difference between Mr. Miller's deſcription and the Linnean character. Dillenius alſo obſerves that the flowers are very apt to fall off. Native of Virginia; alſo of Jamaica, and other iſlands of the Weſt Indies.] Mr. Miller ſays, that the ſeeds were ſent him from the Bahama iſlands.—[Cultivated 1732 by James Sherard, M. D. [e].]

4. The ſeeds of the fourth ſort were ſent me from Carolina, where the plants grow naturally. This riſes with a twining weak ſtalk about five feet high, having trifoliate leaves like the former, whoſe leaflets are narrower, and of a grayiſh colour on their under ſide; the flowers come out by pairs; their calyxes are cylindric. The flowers are ſmall, and of a pale blue colour within, but of a dirty white

[a] Gærtner. [b] Hort. kew. [c] Swartz.
[d] Dillenius. [e] Hort. kew.

on the outſide. This flowers in auguſt, but rarely ripens any ſeeds in England.

[5. Perianth four-toothed, the upper and lower ſegment larger; it is covered with two very ſmall, deciduous bractes. Corolla five-petalled, all the petals oblong and narrow, the ſtandard broader than the reſt, and incumbent. Legume cylindric. Seeds roundiſh. Racemes with two flowers or more[1].

Native of Jamaica, chiefly in the lower hills. It is eaſily diſtinguiſhed by its long reddiſh flowers, milky branches, and ſmooth leaves. It is a weakly climber, and raiſes itſelf by the help of the neighbouring buſhes, to the height of eight or nine feet[2].]

PROPAGATION AND CULTURE.

The ſeeds of theſe plants muſt be ſown upon a good hot-bed early in the ſpring; and when the plants are two inches high, they ſhould be carefully taken up, and each planted in a ſmall pot filled with light freſh earth, and plunged into a hot-bed of tanners bark, obſerving to ſhade them till they have taken freſh root, and refreſh them with water as they may require it. After they are well rooted in the pots, they muſt have air every day in proportion to the warmth of the ſeaſon, to prevent their drawing up weak; their waterings ſhould be repeated two or three times a week, but they ſhould not have too much at each time. As theſe plants have climbing ſtalks, they will ſoon grow too tall to remain under common frames, therefore they muſt then be removed into the ſtove, and plunged into the bark-bed; but if their roots have filled the pots, they ſhould be removed into larger, and afterward they muſt be treated in the ſame manner as other plants from the ſame countries.

All theſe ſorts are annual with us in England, ſo that unleſs the ſeeds ripen, the ſpecies are loſt; and as the two ſorts with double flowers have not formed any pods in this country, ſo far as I have been able to learn, therefore the ſeeds of theſe muſt be procured from the countries where they naturally grow. Indeed theſe are ſuppoſed to be only varieties, which accidentally ariſe from the ſingle. If this be true, I cannot account for the ſucceſs of thoſe plants which grew at Chelſea, for they were all of the ſame double kind, without the leaſt variation; and this was not from a ſingle experiment, but in three different years when I received the ſeeds, the plants did all of them produce double flowers.

Forſt. flor. auſtr. n. 391.
Leaves oppoſite, obovate and elliptic, quite entire, veined; flowers axillary, ſolitary, ſubſeſſile, four-petalled.

DESCRIPTIONS, &c.

Theſe are trees, abounding in a tenacious, glutinous juice. Peduncles ſometimes axillary, but commonly terminating, ſuſtaining one, two or three flowers; on bracted pedicels.

1. Height from twenty to thirty feet. Much reſembling the next ſpecies, but the leaves ſometimes emarginate, and more roundiſh. Flowers large, roſe-coloured and very handſome, but without ſcent. Stigmas, cells and valves ſeven or nine. The whole ſurface of the genitals, and eſpecially of the nectary, is covered with a gelatinous gluten. Fruit green[a]: the ſize of a middling apple, with eight lines running like meridians on a globe, from the ſtalk to the crown of it. When the fruit becomes ripe, it opens at theſe lines, and divides into eight parts, diſcloſing many mucilaginous ſcarlet ſeeds, reſembling thoſe of a Pomgranate; the mucilage being waſhed off, the ſeeds appear white and hard, and contain a kernel: they are contained in the hollow furrows of an octagonal core. The whole tree is exceedingly beautiful, and the ſtructure of the fruit is a moſt exquiſite piece of mechaniſm.

Native of the Bahama iſlands, St. Domingo, and other American iſlands between the Tropicks, on rocks, and frequently on the trunks and limbs of trees, occaſioned by birds ſcattering or voiding the ſeeds, which being glutinous like thoſe of Miſſleto, take root in the ſame manner; but the roots, not finding ſufficient nutriment, ſpread on the ſurface of the tree till they find a decayed hole or other lodgment, wherein is ſome ſmall portion of ſoil: the fertility of this being exhauſted, a root is diſ-

[1] Linn. ſpec. [2] Browne. [a] Jacquin.

charged out of the hole till it reaches the ground, though at forty feet diſtance; here again it fixes itſelf, and becomes a much larger tree. The reſin is uſed to cure ſores in horſes, and inſtead of tallow for boats [1].

Catesby aſſigns the number eight to the diviſions of the capſule, but Jacquin affirms that they vary from ſeven to nine. Catesby's figure is a very good one in all reſpects, except that the corolla is repreſented too flat.

2. Height thirty feet, an elegant tree, and paraſitical on other vaſt trees, like the foregoing: the trunk is frequently a foot in diameter, and ſupports a ſpreading head. The whole abounds in a very tenacious, balſamic juice, of a green colour, but becoming of a browniſh red on being expoſed to the air. Leaves obovate, quite entire, obtuſe, ſhining, coriaceous, firm, marked with obliquely tranſverſe parallel nerves, without any connecting veins, on ſhort petioles, oppoſite, placed chiefly at the extremities of the ſmaller branches. Peduncles ſhort, thick, commonly three-flowered, and terminating. Flowers inelegant, and without ſcent, white, all hermaphrodite, but with the anthers more or leſs polliniferous. Fruits when ripe, ſcarlet. Seeds white, involved in a ſcarlet pulp; the birds are very fond of them, and when the capſules burſt open, hang over them on the wing, and pluck out the ſeeds with the pulp adhering.

It is common in the woods of Martinico, where it is called *Aralie*. The Caribbs uſe the juice for paying their boats *.]

3. The third ſort is pretty common in the Britiſh Iſlands of America, where the trees grow to the height of twenty feet, and ſhoot out many branches on every ſide; with thick, round, ſucculent leaves, placed oppoſite. The flowers are produced at the ends of the branches, each having a thick ſucculent cover: theſe are of different colours in different plants, ſome being red, others yellow, ſome white, and ſome green. After the flowers are paſt, they are ſucceeded by oval fruit, which are alſo of different colours in different plants.

[Browne ſays, that in Jamaica it riſes only to the height of fourteen or fifteen feet, that it grows moſtly on the lower hills, delighting in dry ground, but thriving in moſt light ſoils.

According to Jacquin, it much reſembles the foregoing ſort, the flowers are yellow and inodorous, and ſeem to be ſome female, others hermaphrodite. Browne deſcribes the perianth as conſiſting of ſix or eight roundiſh ſcales, in four rows; the corolla of four thick, oblong-ovate, ſcrew-ſhaped petals; the filaments two, ſometimes three, at each of the interſtices between the petals; the germ thick, roundiſh, obtuſely quadrangular, with twelve diſtinct ſtigmas in a circle round the top of it; the capſule thick, roundiſh, many-valved, twelve-celled, containing many roundiſh ſeeds in a ſaffron-coloured pulp.

Wherever the trunk or larger branches are wounded, they throw out a thick relinous gum, which is ſometimes uſed as a vulnerary among the inhabitants of Jamaica; but it has not any extraordinary ſmell, or pungent taſte.]

Cultivated by Mr. Miller in 1759. He informs us that there were ſome fine plants in the garden of Mr. Parker, near Croydon in Surry, which were brought over in tubs from Barbadoes: and that there are three varieties differing in the ſize and colour of the flowers and fruit.

4. This tree riſes to the height of twenty (or thirty) feet: it has very large oval ſpear-ſhaped leaves, ending in points, placed alternate on the branches, and having ſeveral ribs, which go off from the midrib alternate, riſing upward to the ſide of the leaves; and alſo a great number of ſmall veins, running horizontally between theſe ribs. The borders of the leaves are ſerrate, and their under ſides are of a ſhining brown colour. The branches are covered with a woolly down, and the flowers are produced in looſe ſpikes at the end of the ſhoots; theſe are ſmaller than thoſe of the foregoing, and are of a roſe colour.

[According to Jacquin, the corolla is white, and an inch and an half in diameter. The leaves are four inches long. It is a native of the moiſt mountainous woods of Martinico, where it has the name of *Paletuvier de montagne*.] Mr. Miller ſays, it was diſcovered by Dr. Houſtoun at Campeachy, whence he ſent dried ſpecimens and ſeeds.

[5. Native of New Caledonia. Found ſeptember the 9th, 1774.

6. Native of Tongatabu. Found october the 8th, 1774 [1].]

PROPAGATION AND CULTURE.

The beſt method of having theſe plants, is to procure them from the Weſt Indies, to be brought over in tubs; for the ſeeds ſeldom ſucceed, and the young plants grow ſo ſlowly, as not to make any figure for ſome years. In bringing them over, great care ſhould be taken, that they do not receive much wet, for having very ſucculent ſtems, moiſture will cauſe them to rot.

The plants are tender, and muſt be conſtantly kept in the ſtove, otherwiſe they will not live through the winter in England; they muſt alſo be watered very ſparingly, eſpecially in winter, for they naturally grow in thoſe parts of the iſlands, where it ſeldom rains.

They may be propagated by cuttings, which muſt be laid to dry when they are cut off from the plants for a fortnight or three weeks, that the wounded part may be healed over, otherwiſe they will rot. When the cuttings are planted, the pots ſhould be plunged into a hot-bed of tanners bark, and now and then gently refreſhed with water: the beſt time for planting theſe cuttings is in june or july, that they may be well rooted before the cold weather comes on in autumn. In winter theſe plants may be placed upon ſtands in the dry ſtove; but if in ſummer they are plunged into the tan-bed, they will make great progreſs, and their leaves will be large, in which conſiſts the great beauty of theſe plants.

Leaves elliptic-lanceolate, flowers lateral tomentoſe.]

DESCRIPTIONS, *&c.*

1. Stem ſhrubby, ſix or eight feet high, putting out many ſide branches which grow erect. Leaves of a grayiſh colour, and entire. The flowers come out from the joints, at the ſetting on of the leaves, towards the upper part of the branches; they are ſmall, and of a greenith white, appear from june to auguſt, and make no great appearance.—[Leaves rugged about the edge. Flowers erect, according to Linneus. Cultivated 1692, in the royal garden at Hampton Court [a].]—Mr. Miller informs us, that plants with male flowers had been long in the Engliſh gardens, but that thoſe which bear female flowers were introduced afterwards.

[2. Leaves alternate, linear-lanceolate, gradually narrowed to the end, mucronate, quite entire, even. Flowers uſually two together, pendulous, ſmall. Native of the Cape of Good Hope [b].]

3. This riſes about the ſame height with the firſt, but has a ſtronger ſtem. The leaves are much larger, ſea-green, and on petioles an inch long. The flowers are like thoſe of the firſt ſort in ſhape and colour, but thoſe on the male plants are ſmaller, and grow cloſer together than thoſe of the female, but both are ſuſtained upon ſhort foot-ſtalks. Theſe flowers appear at the ſame time as thoſe of the firſt ſort, and the ſeeds ripen in autumn. I have raiſed ſeveral of theſe plants from ſeeds, which have all proved female, the ſame as the parent plant.

[Capſule, as deſcribed by Gærtner, pedicelled or ſeſſile, globular, rugged, with raiſed dots, with three grooves and tricoccous; the cocci or component parts are of the ſubſtance of paper, gibbous on one ſide, angular on the other, ſemibivalve, the back of the valves ſeparating ſpontaneouſly from the partitions, which are membranaceous, permanent in the axis of the fruit, dark cheſtnut-coloured, thining, ſerrulate on the edge. Seeds ovate, dark cheſtnut-coloured, with a two-lobed white umbilical gland immediately below the tip on the inſide.

Cultivated 1739, by Mr. Miller:] who ſays that there were no plants in England with male flowers, till he received one from Dr. Job Baſter of Zirkzee in Holland.

[4. This is a very branching ſhrub. Branches round, ſmooth, tubercled with fallen leaves, uſually ſcattered, but ſometimes coming out three together. Leaves petioled, quite entire, netted-veined, oblong, a little narrowed towards the baſe. The flowers come out towards the ends of the branches and branchlets, and are ſubſeſſile. Calyx hirſute on both ſides, eſpecially without, aſh-coloured, with ſhort hairs; leaflets roundiſh, concave. Petals oblong, minute, ſmooth. Style trifid, involved in aſh-coloured hairs [c].

Found at the Cape of Good Hope by Thunberg.

5. A ſhrub, three feet in height, very branching, erect, tubercled with the ſcars of fallen leaves; branches round, pubeſcent. Leaves crowded, ſeſſile, ſomewhat acute, the ſize of Thyme leaves. Flowers lateral, ſolitary, ſeſſile, longer than the leaves, white: calyx five-toothed, tomentoſe on the outſide. Petals oval, the length of the calyx. Stigma bearded.—Sandy ſhores of the Cape; flowering in may.

6. Leaves on ſhort petioles, alternate, obtuſe or retuſe, the ſize of thoſe of Beech, the edge reflected, with prominent tranſverſe veins or nerves underneath. Racemes axillary, very ſimple, from the ends of the branches divided into three or four alternate peduncles; all filiform, longer than the leaves. Leaflets of the calyx acute. Petals very ſmall, three-toothed. No nectaries, but a ring ſurrounding the receptacle. In the middle a column, with five horizontal filaments, and verſatile anthers. Rheede ſays that the fruit is a berry [d]. Native of the Eaſt Indies.

7. This is a tree with round branches. Leaves alternate, petioled, ovate or cordate-lanceolate, blunt, quite entire, with orbicular ſcales on both ſurfaces. Racemes branched, axillary, and terminating. The male flowers have ten ſubulate ſtamens, the length of the corolla; with erect compreſſed anthers. Petals oblong, obtuſe, ſeſſile, ſpreading. Other flowers have twelve ſtamens, with a piſtil perfectly like that of an Euphorbia [e].]

According to Miller, it riſes with an upright ſhrubby ſtalk, not more than three or four feet high in England; but in places where it grows naturally, it riſes upwards of twenty feet in height, with the branches forming a large ſpreading head. The leaves are ſhaped like thoſe of the Black Poplar.

[On breaking the more tender branches, a large drop of a thick balſamic liquor oozes from the wound, whence it has the appellation of Balſam-tree. It grows frequently to the height of four or five feet. The leaves and tender tops are ſaid to heal ſores, and are frequently uſed in baths and fomentations [f].

[a] Hort. kew. [b] Linn. ſpec.

[a] Vahl. [c] Linn. zeyl. [d] Linn. amoen. & cliff. [f] Browne.

Swartz, who makes this a ſpecies of Croton, doubts whether the fourth Croton of Browne be the ſame plant.

Native of both Indies, and cultivated by Mr. Miller.

The *Cortex Caſcarillæ* is ſuppoſed to be the produce of this tree. At the end of the laſt century it was recommended by Stiffer as a powerful diuretic and carminative, and he uſed it with ſucceſs in calculous, aſthmatic, phthiſical, ſcorbutic, and arthritic complaints. Since that it has been uſed in Germany for the Peruvian bark in intermittent fevers: and the German phyſicians have given it much credit as an aſtringent, and have accordingly uſed it in hæmorrhages and various alvine fluxes[a].

8. Branches flexuoſe, tomentoſe. Leaves ovate or oval, rather large, quite entire, on ſhort petioles. Stipules ovate, acute, the length of the petioles. Flowers axillary, ſubſeſſile, not longer than the ſtipules, dark purple. Calyx one-leafed, bell-form at the baſe, five-parted, acute, permanent. Petals roundiſh, very ſhort, inſerted into the ſinuſes of the calyx. Style columnar, ſcarcely triſid at the end.—Native of the Eaſt Indies[b].

9. Native of the Cape. It reſembles *Andrachne ſcleroides*[c].

10. This bears a great affinity to *C. pulchella*, and ſhould be placed next before it. *C. lanceolata* however differs from that, in having the branches purple, and aſh-coloured-villoſe at top. Leaves broad-lanceolate, two inches long and more, without any dots beneath, few only above, and they viſible only with a magnifier. Calyxes villoſe-tomentoſe. Capſules not dotted. Male flowers copious, aggregate, ſubpeduncled, in the axils. Female flowers ſubſolitary, peduncled. Corolla, ſtamens and piſtil as in *C. pulchella*[d].]

PROPAGATION AND CULTURE.

1. 3. Theſe plants are eaſily propagated by cuttings during any of the ſummer months: if the cuttings are planted in ſmall pots, and plunged into a very moderate hot-bed, and ſhaded from the heat of the ſun in the middle of the day, they will ſoon take root, and ſhould then be inured to the open air, otherwiſe they will draw up very weak; afterward theſe plants may be each put into a ſeparate ſmall pot, and placed in a ſheltered ſituation, where they may remain until the middle of October, or later, if the weather continues mild, when they ſhould be removed into the green-houſe, and placed where they may have the free air in mild weather, for they only require to be protected from froſt, therefore require no warmth in winter; but if the green-houſe is ſhut up too cloſe, or the plants are much ſhaded by others, the tender ſhoots are ſubject to grow mouldy, which deſtroys more of theſe plants than the cold. In the ſummer they muſt be placed abroad in a ſheltered ſituation, with other hardy exotic plants.

As theſe plants are always green, they look well in the green-houſe during the winter ſeaſon; and in ſummer, when they are placed in the open air with other exotic plants, they make a pretty variety.

7. This plant will live through the winter in an airy glaſs-caſe, without artificial heat: but in that ſituation ſhould have very little water, for the plants abounding with a milky juice like the Euphorbia, muſt at no ſeaſon of the year have too much wet. If theſe plants, when young, are placed in a very moderate warmth in winter, it will greatly forward their growth, but they muſt not have too much heat, for that will force them too much; and when the plants have obtained ſtrength, they may be treated more hardily. This ſort may be propagated by cuttings during the ſummer ſeaſon; but the cuttings ſhould be laid in a dry place for a few days, when they are taken from the old plants, that their wounded parts may dry and be healed over before they are planted. Theſe muſt be planted in ſmall pots filled with light ſandy earth, and plunged into a moderate hot-bed of tanners bark; and if the ſeaſon is very warm, the glaſſes ſhould be ſhaded in the heat of the day, and raiſed up to admit freſh air to the cuttings every day; theſe muſt be ſparingly watered. When they have taken root, and begin to ſhoot, they muſt have a greater ſhare of air, and by degrees be inured to the open air; and when their roots have filled the pots, they ſhould be carefully parted, and each planted in a ſeparate pot of the ſame light ſandy earth; then they ſhould be placed on the back part of the ſtove, behind the other plants, where they may be ſcreened from the ſun till they have taken freſh root, after which they may be brought forward, and expoſed gradually to the open air. In the ſummer they ſhould have free air conſtantly in warm weather, but they muſt be ſcreened from heavy rain; and in winter placed in an airy glaſs-caſe, where they may enjoy the ſun, and during that ſeaſon have very little wet.

DESCRIPTIONS, *&c.*

1. It is a low annual plant, ſeldom more than four inches high: ſtems ſlender, [hardiſh upright, branched at bottom, tinged with red, covered with ſhort

ſhort whitiſh hairs. Leaves ſpatulate, alternate, ſeſſile, glaucous, with minute ſtars of hairs all over the ſurface. Flowers in terminating ſpikes, and very minute. Corolla yellow, the ſize of the calyx. Style ſcarcely viſible with a magnifying glaſs [a]. Silicle ſubobiculate, very ſlightly emarginate, leafy compreſſed, pubeſcent, ſurrounded with a paler or whitiſh, very finely ciliate edge, one-celled, not opening ſpontaneouſly, but eaſily diviſible into two very ſlender membranaceous valves. Seed ſingle, elliptic, compreſſed, ſmooth, tawny-coloured [b].

Villars doubts whether this plant be diſtinct from *Alyſſum minimum* of Linnæus.

Native of the South of France, Spain, and Italy. Flowering there from march to may; but with us from may to july. Cultivated 1739, by Mr. Miller [c].

2. Root perennial, woody, branched. Stems ſhrubby, diffuſed, leafy at the end. Leaves hirſutely hoary; the lower ovate-oblong, ſinuate, three inches long, and half an inch broad; the ſtem-leaves alternate, ſeſſile, linear-lanceolate, entire or toothletted. Flowers terminating and axillary, at firſt in a ſort of umbel, but afterwards panicled; calyx very ſmall, hairy on the outſide; petals yellow, emarginate, longer than the calyx. Silicles obcordate, alternate, pedicelled, two-celled with one ſeed in each cell; diſpoſed in a ſpike from two to three inches in length [d].

Firſt obſerved in the Levant by Tournefort.—Arduini had the ſeeds in 1755 from Leonard Seller, who cultivated this plant many years in his garden at Venice. He and Lamarck agree with Tournefort in referring this and the next ſpecies to the genus *Alyſſum*, and to make amends they tranſport the *Peltaria* to this genus. In this natural claſs, the diviſion of the genera is frequently arbitrary, and there would be no end to removals.

3. Stems much branching, diffuſed, evergreen. Leaves linear-lanceolate, whitiſh, not ſtiff. Racemes ſtriated. Calyx deciduous. Petals white, obovate, the claws and filaments dark purple. Anthers yellow. Filaments toothleſs; in which circumſtance alone it differs from the *Alyſſums*, with which it might very well be aſſociated [e].

According to Ray; root perennial. Branches ſtriated. Leaves an inch in length, taſting like Creſs. Corollas white, darker in the middle, reſembling thoſe of Water-Creſs.—It has the appearance of Wall-flower, but the branches are weaker, and both they and the leaves are much ſmaller.

Native of the South of France, Spain and Italy; common on the coaſt of the Mediterranean. Cultivated by Mr. Miller in 1759.]

PROPAGATION AND CULTURE.

Theſe are low plants, that have little beauty, and are preſerved chiefly in botanic gardens. The firſt is propagated by ſeeds, ſown on a border of light earth, where they are to remain. If ſown in autumn, the plants will grow larger, flower earlier, and ripen ſeeds with more certainty. If theſe be permitted to ſcatter, the plants will thrive without farther care.

3. The third ſhould be ſown upon a warm border in a dry ſoil, and does not bear tranſplanting well.

DESCRIPTION, *&c.*

1. This is an humble ſhrub, which ſeldom riſes more than two feet and a half high in this country, but ſpreads out on every ſide with many lateral branches, ſo as to form a thick buſh. The ſtems ligneous, and almoſt as hard as thoſe of the Box-tree, and the wood is of a pale yellow colour under the bark: the branches are garniſhed with thick ſtiff leaves, of an oblong oval ſhape, about an inch and a half long, and a quarter of an inch broad, of a dark green colour, having a ſtrong vein or rib through the middle. The flowers are produced ſingle from the wings of the leaves, toward the extremity of the branches; they are of a pale yellow colour. After the flowers are fallen, the germ becomes a fruit, compoſed of three ſeeds joined together after the ſame manner as thoſe of Euphorbia or Spurge; theſe are firſt green, afterwards turn of a brown colour, and when ripe are black.

[The fruit is thus deſcribed by the accurate Gærtner. It conſiſts of three ſmall berried drupes, gibbous on one ſide, and angular on the other, joined at a common axis, dark brown when ripe: fleſh thin, herbaceous: ſhell bony, thick, ſubglobular, wrinkled, with a groove and umbilical hole on the bells, two-celled, valveleſs: one of the cells, placed behind the other, both at the ſeat of the radicle, divided by a thin partition, ſo that the upper part of the ſhell appears to be four-celled. In each cell there is a ſingle, ſmall, ovate ſeed, doubled together like a worm, white with a brown caruncle at the inſertion of the navel.]

The flowers begin to appear in may, and are ſucceeded by others during the ſummer months: and, when the autumn proves favourable, theſe ſhrubs will continue in flower till the end of october.

As this is a low evergreen ſhrub, it may be very ornamental, if placed in the front of plantations or evergreen trees and ſhrubs: for as the branches grow pretty compact, and are well garniſhed with leaves, it will hide the ground between the taller ſhrubs better than moſt other plants: and, being durable, will not want to be removed.

[Native of the South of France, Italy and Spain; in hot, dry, barren and rocky ſoils.—Cultivated in 1596, by Gerarde [f].]

PROPAGATION AND CULTURE.

This was formerly preſerved in green-houſes, and thought too tender to live in the open air in England; but it has now long been planted in the full ground, where it reſiſts the cold of our ordinary winters very well, and is ſeldom injured but by extreme hard froſts; nor do theſe kill the plants which grow upon dry, rocky, or rubbiſhing ſoils, where their ſhoots are generally ſhort and firm: but in moiſt rich ground, where the ſhoots are more luxuriant, they are ſometimes injured.

It is propagated by ſeeds, which ſhould be ſown in autumn ſoon after they are ripe, and then the plants will come up the following ſpring: whereas thoſe which are not ſown till the ſpring, will remain a year in the ground, and often miſcarry; theſe ſeeds may be ſown in a bed of common earth, co-

[a] Carmilles. [b] Gærtner. [c] Hort. kew. [d] Arduini. [e] Linn. mant.

[f] Hort. kew.

vering them half an inch deep, and will require no other care but to keep the plants clear from weeds the following ſummer; and in the autumn following, the plants may be tranſplanted where they are to remain.

DESCRIPTIONS, &c.

[Some of the ſpecies approach to *Carduus*, others to *Serratula*, and *C. Acarna* to *Carthamus*: hence Lamarck has ſuppreſſed this genus, inſerting ſome of the ſpecies among the *Cardui*, and others among the *Carthami*; from which Linneus ſeparates the *Cnicus* principally becauſe the ſcales of the calyx are ovate and branch-ſpiny; whereas in *Carthamus* they are narrowed at the baſe, and have a leafy, ovate, ſpreading appendicle at the top[a].

1. Calyxes lateral, ſeſſile, uſually two together, with one between on a ſhort peduncle. A white line runs along the keel of the calycine ſcales[b]. There are very ſmall, bifid appendixes to the anthers, as in *Carlina vulgaris*[c]. The calyx is ſurrounded with bractes, ſcales branch-thorny. Leaves ſmooth, ſtem-claſping[d].—In the woods of Switzerland, near brooks, it grows to the height of ſix feet, with the leaves more thorny, and the branches, in the mature ſtate of the plant, more elongated and leafleſs: it is then very like to *Carduus tataricus Jacqu. auſtr. t.* 90[e]. Flowers pale yellow.

Native of moſt countries of Europe, except the moſt ſouthern; flowering in july and the autumnal months, in moiſt woods, meadows and marſhes.——The Ruſſians boil the leaves in the ſpring, and eat them as Coleworts. No cattle touch it for food, according to *Schreber*.—Cultivated in 1570, by Mr. Hugh Morgan[f].

Mr. Miller's deſcription of *Cnicus Eriſithales* ſeems to belong to this ſpecies.

2. Leaves pinnate-parted, ſeſſile, pubeſcent eſpecially underneath. Peduncles leafleſs. Flowers ſolitary, nodding, yellow; diſk convex, rather long[g].

Stem three feet high and more, angular, ſometimes a little tomentoſe, not branched, unleſs at the top, naked far under the flowers. Flowers three or four, frequently two oppoſite, ſeſſile, never guarded with bractes, ſeldom ſolitary, nodding in a ſtate of maturity: calyxes conic; ſcales lanceolate, awned but not thorny: florets purple, yellow, or white with purple ſtamens and piſtil[h].

Stem from three to five feet high, hairy. Lower leaves a foot in length. Flowers as far as ſix. Calyxes roundiſh, ſmooth; ſcales reflected at the end. Filaments hairy; anthers putting forth two little briſtles behind. Seed two lines long, ſtipital, with the angles obtuſe, crowned with a ring, whence ariſe

[a] Juſſieu and Cavan. hiſp. 40. [b] Linn. ſpec. [c] Leers. [d] Willdenow. [e] De la Chenal. obſ. bod. 8. 141. [f] Hort. kew. from Lobel. [g] Linn. ſyſt. [h] Haller.

feathered

feathered rays, as far as forty. Floſcules pale yellow, varying to red or purple and fleſh-colour.—The geſtation of this ſpecies laſts a month; the leaves on the ſtem ariſe to nine: the terminating ſegment of them is trifid, the lower pinnas are confluent with the ears, the branches bear two or three flowers, are long, and leafy; the leaves are lanceolate [1].

France, Switzerland, Auſtria, Carniola, Sileſia. It begins to flower in june.—Introduced 1787, by Monſ. Vare. Perennial [b].

3. This ſpecies reſembles *Carduus eriophorus*. Stem firm, deeply grooved, covered with a cobwebby pubeſcence. Leaves ſtem-claſping, lanceolate, deeply pinnatifid; pinnas ſimple and two-lobed ending in a ſtrong ſpine; not only the whole margin, but the ſurface of the leaf is ſtrigoſe and ſet with thorns. A large head of white or purple floſcules terminates the branches, and is guarded with linear ſtrigoſe bractes having ſmall ſpines about the edge. Scales of the calyx as in *C. eriophorus*. Biennial [c].

South of France and Piedmont.——It flowers in july and auguſt. Introduced 1775, by Monſ. Thouin [a].

4. Root perennial, black. Stem upright, hollow, from two to five inches high, thickened at top, very cloſely covered with white hairs. Leaves many both at the root and on the ſtem, ſharp, three inches long, ſome quite entire, others toothletted, unarmed, the ſides rolled back, grooved on the upper ſurface where the midrib projects on the under, hairy, eſpecially beneath and near the ſtem, deep green above, pale green underneath. Flower ſolitary, terminating, erect, very large in proportion to the plant, ſeſſile in the uppermoſt ſhorter leaves. Scales of the calyx lanceolate, acuminate, hairy, ciliate, pale green with a purple baſe, the inmoſt erect, the outer patulous at the tip. Corollets purple; tube long and ſlender, ſpread out into a wide and then an ovate form, ſegments linear, obtuſe, equal, ſhort; in the outer florets very much curved in, but in the central ones ſtraight. Anthers violet-coloured. Stigma bifid, purple. Calyx unchanged when in fruit. Hairs on the receptacle white, capillary, the length of the calyx. Seeds oblong, obſcurely angular, ſmooth, brownith, crowned with a ſeſſile, plumoſe, long egret. It flowers in july and auguſt.

Native of the mountains of Auſtria [a]. Found alſo on mount Grindoviz in 1761, by Scopoli, who ſays that his ſpecimens are leſs villoſe, the leaves fewer and with only a ſingle toothlet or two, the calycine ſcales puliſhed on the inſide, the ſeeds compreſſed, crowned with a pale egret three times as long as the calyx, and the receptacle rough with briſtle-ſhaped chaffa. He refers it to the genus *Cirſium*, and Jacquin to that of *Serratula*.

5. Stem herbaceous, winged by the leaves running down it, hoary, a foot high, but ſometimes much ſmaller. Leaves ſeſſile, ſcattered, extremely acute, hoary, keeled, having a few teeth about the edge, with two or three yellow ſpines in each. Calyx woolly; ſcales linear, ending in pinnate, innocuous, yellow ſpines; and intrenched in leaves that are very prickly, like the ſtem-leaves but ſhorter. Corollets purple. Seeds ovate, tharp at the baſe, ſomewhat compreſſed, ſhining, yellowiſh white, crowned with a feathered egret, half an inch long, ſpreading out into a ball [e].

This has the habit of *Carlina*, and the appearance of *Carthamus*. Stem ſimple, corymbed at the top. Leaves adnate, becoming hoary, ciliated with tranſverſe, yellow, double ſpines. Flowers terminating, afterwards axillary, ſeſſile. Calyxes oblong, imbricated with ſcales having harmleſs ſpines at the end, but pinnate with five ſpreading ſpinules. Corollas ſmall, purpliſh [f].

It is a native of the South of France and of Spain, and was cultivated in 1683, by Mr. James Sutherland [g].

[1] Scopoli. [a] Hort. kew. [b] Allioni. [c] Hort. kew. [d] Jacquin. [e] Cavanilles. [f] Linn. ſpec. [g] Hort. kew.

6. Stem unbranched, twelve to eighteen inches high; the top entirely covered with leaves, angular not winged. Stem-leaves moſt fiercely thorned; pinnas angular, many-lobed, the nerves continued into ſtrong thorns: the leaves on the top of the ſtem form a neſt for the flower, broader, ovate-lanceolate, pinnate, whitiſh yellow, pubeſcent. Calyx connate, with lanceolate ſcales, ending in a ſtout ſpine. Floſcules pale yellow [a].

The ſtem of our plant is twice as long as in Haller's figure, grooved, villoſe. Leaves ſubdecurrent, villoſe above, beneath having thick hairy nerves. Flowering heads as far as eighteen. Calycine ſcales ſmooth, erect [b].

Haller affirms that Gmelin's plant is not the ſame with his.—Native of Switzerland, Auſtria, and Carniola. Perennial. In gardens it riſes to the height of four feet.

7. Leaves large, long, winged, the colour and form of Artichoke leaves, hoary underneath. Stem three feet high, angular, putting forth few branches, and having at the top heads the ſize of a ſmall Artichoke, and of a tawny colour. Corollas purple. Native of the Pyrenees [c].

It flowers in july and auguſt, and was cultivated here in 1640 [d].

8. Stem two feet high, erect, ſubangular, the thickneſs of the little finger, ſcarcely lanuginoſe, one-flowered. Leaves very many, unarmed, ſeſſile, ſomewhat hoary; the upper ſmaller and more entire: root-leaves large, petioled; the ſegments lanceolate, ferrate. Flower one, terminating, ſeſſile; calyx large, globular, ſcales imbricate, looſe, ovate, gray; corolla large, violet; floſcules ſix-cleft, with linear, acute ſegments; ſtamens and ſtyle longer than the corolla, the former white, the latter violet. There are no barren floſcules.—Native of Siberia. Perennial [e].

9. Root perennial, large, and rough, ſending out many thick, black fibres, which ſtrike deep in the ground. The leaves which riſe immediately from the root are near a foot long, and ſix inches broad in the middle, diminiſhing gradually toward the point, but at the baſe ſwelling out almoſt heart-ſhaped; their petioles are bordered, and the borders are cut and curled, embrace the ſtalks half round, and end in ſpines; they are of a deep green on their upper ſide, but white on their under, and are ſharply ſerrate on their edges. The ſtalks riſe ſix or ſeven feet high, ſending out a few ſmall branches; they are ſtriated, of a brown colour, and at bottom have heart-ſhaped leaves, half-ſtem-claſping; the leaves toward the top of the ſtalk are long and narrow, ending in acute points. Each branch is terminated by one large head of flowers: calycine ſcales imbricate, ending in a ſharp ſpine; florets pale yellow, with an agreeable ſcent. It flowers the ſecond year from ſeed in july, and the ſeeds ripen in the autumn, when the plant decays.—Native of Siberia, whence the ſeeds were ſent to the imperial garden at Peterſburgh, and were communicated to Mr. Miller [f], who cultivated them at Cheſea in 1758 [g].]

The inhabitants of Siberia eat the tender ſtalks, boiled.

PROPAGATION AND CULTURE.

Theſe are perennial plants, which may be propagated by parting the roots: the beſt time for doing this is in autumn, that the plants may get good root in winter; for thoſe which are tranſplanted in the ſpring, do not flower well the firſt year, unleſs they are planted in a moiſt ſoil. As theſe plants grow very large, they are not proper furniture for ſmall gardens, where they will take up too much room; for they ſhould not be planted nearer than four feet from each other, for if they are too near any other plants, they will rob them of their nouriſhment; for the roots of theſe extend to a great diſtance, ſo that two or three for variety, are ſufficient for any garden, and may be planted at a diſtance from choicer plants.

[a] Haller. [b] Scopoli. [c] Morifon. [d] Hort. kew. [e] Linn. mant. [f] Mill. ſp. [g] Hort. kew.

They

They are alſo propagated by ſeeds, which may be ſown in the ſpring on a bed of common ground, and will only require to be thinned, and kept clean from weeds till autumn, when they may be tranſplanted where they are deſigned to remain.

DESCRIPTIONS, *&c.*

1. This is a lofty ſpreading branched irregular inelegantly formed tree, but rendered handſome by its leaves and fruits. Bark cinereous, thin, in the younger trees ſmooth, in older ones full of chinks. Timber hard ponderous red, but fit for little uſe except to burn on account of its fibrous texture, unleſs it ſhould be found ſerviceable in dying. Leaves quite entire, ending in a ſhort blunt point, coriaceous thick large alternate deep green, with the midrib and veins connected with it more or leſs ſcarlet, on ſhort petioles ſheathing at the baſe. Racemes ſimple round thick upright terminating ſolitary very long, when in fruit pendulous; the pedicels one-flowered numerous and ſhort. Flowers ſmall whitiſh, ſmelling like thoſe of the Cherry. Style ſingle, or divided deeply into three ſegments, or triple; which variation takes place alſo in the other ſpecies. Baſe of the filaments widening, and they are commonly connected there*.

The berries are of the ſize of Grapes, having under an outward reddiſh-brown or purpliſh membrane, a

* Jacquin.

ſoft

soft thin pulp, not unpleasantly astringent, covering a large round stone, containing a kernel [e].

Gærtner calls the fruit a superior drupe formed of the berried calyx, obovate, of a purple colour with a bloom becoming black when ripe, and wrinkled: pulp soft drying into a thin crust. Shell thin like paper, intimately united with the pulp and half-three-celled: partitions membranaceous narrow, to be found only at the bottom of the drupe. Seed single, subglobular, acuminate above, deeply umbilicate below, three-lobed, striated and wrinkled, of a ferruginous brown colour.

The fruit is a very great astringent, and may be used in emulsions, boluses or electuaries, but its action is not of long continuance: it has all the taste of Bistort. The berries have an agreeable flavour, but the pulp is not considerable. This tree is common in most of the sugar-colonies, and is generally found near the sea. It frequently grows to a considerable size, and is then looked upon as a beautiful wood for all sorts of cabinet-ware; but it seldom rises straight or regular [a]. The Spaniards call it *Uvero*, and the French *Raisinier du bord de la mer*.

Introduced 1696, by Mr. Bentick [a].

2. This is an upright tree, sixty or eighty feet high: the head has frequently no more than two or three thick branches, but little divided and irregular. The bole of the tree is sometimes forty feet in length, and puts forth a branch or two about the middle. The timber is deep red, heavy, very hard, and also incorruptible, but it is brittle; when used for posts, the part under ground becomes hard as stone. Leaves roundish, cordate, quite entire, very much veined and wrinkled, frequently extremely hirsute, sometimes however almost smooth, alternate, few, two feet in diameter, on a short petiole sheathing at the base.

It is common in the thick mountainous woods of Martinico [f]. Browne says, that in Jamaica it seldom rises above five or eight feet in height; and that the berries are not esteemed. Jacquin had not seen the flower or fruit, but was informed that the latter is eatable. The French inhabitants call it *Bois a grandes feuilles*. Jacquin cultivated it at Vienna about the year 1755; and Mr. Miller here in 1768.]

3. This grows to a very large size, and the leaves, flowers and fruits are all large: the leaves are very smooth and of a lucid green.

[Browne informs us that it grows to a considerable size in Jamaica, and is looked upon there as a fine timber wood.

It was introduced here before 1733, by William Houstoun, M. D. [a]

4. This tree grows to the height of twenty feet, is upright, and the boughs form a head. Leaves quite entire, wrinkled, petioled, alternate, half a foot long. Racemes terminating, solitary, simple. Flowers small, yellowish. The calyx becomes thick, succulent and snow-white, covering to the middle a three-sided, black, shining nut. The fruit is sweet and pleasant. The French call it *Raisinier de coude*.—Native of St. Domingo, Jamaica, and Martinico [a].

5. This is a small upright branching tree, ten feet high. Leaves veined coriaceous, only half the size of those on the first sort. Native of Port au Prince and Leogane in St. Domingo.

6. This is also a small, very branching, irregular tree, about twelve feet high, with smooth ash-coloured branches. Leaves quite entire, shining, coriaceous, veined, commonly slightly widening at the top, flat, alternate, petioled, numerous. Racemes simple, terminating, solitary, on alternate distich young twigs. Flowers small, white. The leaflets of the calyx increase and become succulent, closely embracing a dark shining nut, frequently naked at the end; however they continue permanent, not uniting into a drupe. Whence this species seems nearly allied to *Polygonum*. The fruit is astringent. Native of Carthagena. Flowering in auguſt [i].

7. A small branching tree, twelve feet high. Leaves quite entire, coriaceous, shining, somewhat rigid, almost veinless, yellowish green, petioled, alternate, numerous. Racemes simple, terminating, erect. Drupes roundish, dark purple, the size of a large pea; the pulp sweet and eatable. Native of Domingo, at Port au Prince.

8. A small upright branched tree, fifteen feet high. Leaves quite entire, subcoriaceous, veined, shining, alternate, half a foot long, commonly two or three on each flowering branchlet, on petioles sheathing at the base. Racemes terminating, simple, solitary, erect, scarcely an inch and half long. Flowers white. Almost the whole receptacle, with a small part only of the calyx, becomes a roundish drupe, of a dark red colour, and a sweetish but austere taste. Native of Carthagena.

9. This tree agrees very nearly in habit with *C. leoganensis*. The leaves are very deeply emarginate at the tip, commonly at an acute angle, and are scarcely coriaceous. Native of the West Indies. It is *Guajabasa foliis rotundioribus* of Houstoun's catalogue, and is in Mygind's herbarium.

10. This has the habit of *C. urvifera*. The leaves are very coriaceous, five inches long, waved on the edge; the petioles are slightly covered with a ferruginous toment. Bark of the branches cinereous. Wood red. It is named in Houstoun's catalogue G. fol. oblongis, and is also in Mygind's herbarium [k].]

11. This is of humbler growth than any of the former: the flowers and fruit are smaller than those of the other sorts. [It recedes from the other species, in having membranaceous not coriaceous leaves; the petioles surrounded with a membrane instead of a stipule, and not issuing from their back; racemes terminating and quite simple; flowers scattered and pedicelled [l].

The calyx is seldom divided into more than three parts, and the nut is triangular. The flowers are small and disposed in simple axillary spikes in all the species. The petioles of the leaves are strong and sheathed at the bottom [m].

Native of Jamaica.

12. Native of New Zealand; found at Charlotte Sound. It seems rather to be a *Polygonum* by the drawing in Sir Joseph Banks's collection.

13. Stem suffruticose, branching. Leaves subacuminate, quite entire, coriaceous, alternate. Flowers white in loose racemes. Calyx bell-shaped. Style cloven half way, nearly equal to the calyx, with three roundish stigmas. Fruit a roundish five-lobed berry, formed from the five segments of the calyx, blackish, pellucid and small, including one, three-sided, acuminate seed.

Native of Cochinchina, in hedges and among bushes.

14. This has the stem, leaves, and fructification as in the foregoing sort; but the flowers are more numerous and heaped together in sessile cymes.

In the hedges of Cochinchina [n].

All the species are either trees or shrubs bearing their flowers in racemes or bunches.] except the three last, they are natives of the West Indies; some on the sea shores, where they form almost impenetrable thickets. The fruit of the first sort is frequently eaten by the inhabitants, but especially by the negroes: the other sorts are chiefly food for birds.

PROPAGATION AND CULTURE.

The plants of all the sorts are easily propagated by seeds, when they can be obtained fresh from the places of their natural growth (for none of the sorts have as yet produced either fruit or flowers in England.) The seeds should be sown in small pots filled with earth from the kitchen-garden, and plunged into a hot-bed. If the seeds are good,

[a] Sloane. [b] Browne. [c] Hort. kew. [d] Jacquin. [e] Hort. kew. [f] Jacquin. [i] Jacquin. [k] Ibid. [l] Linn. amoen. [m] Browne. [n] Loureiro.

and the bed of a proper temperature of warmth, the plants will appear in five or ſix weeks, and will be fit to tranſplant in about a month after; when they ſhould be ſhaken out of the pots, ſeparating their roots carefully, and each planted in a ſeparate ſmall pot filled with the like earth, plunging them into a hot-bed of tanners bark, being careful to ſhade them in the day time, until they have taken new root; after which they ſhould be treated as other tender exotic plants, which require to be conſtantly kept in the bark ſtove.

DESCRIPTIONS, &c.

1. Root perennial. Stem angular, branching. Root-leaves kidney-ſhaped, entire, veined, ſmooth, fleſhy, obtuſe, with ſeven callous obſcure crenules, ſometimes ſlightly angular, on long petioles. Stem-leaves oblong, ſeſſile or claſping, the lower ones ſometimes on broad petioles, deep green, ſlightly toothed, or with a few large angular dents on the edges. Petals fleſhy, clear white with greeniſh claws. Silicles oval, gibbous, ſmooth, either not emarginate or ſcarce ſenſibly ſo, on long ſlender peduncles, ſpreading and ſometimes bent back: partition double, in each cell four rough ſeeds*.

Sea ſhores of the north of Europe: alſo on mountains. With us on the coaſt of Norfolk near Lynn and Yarmouth; near Hull, Boſton, Whapload, Holbeach; in Cornwall, Cumberland, Lancaſhire, Wales: and at a great diſtance from the Sea near Caſtleton in Derbyſhire, Penigent, Ingleborough, and Stanemore in Yorkſhire; near Settle, on the highlands of Scotland, and mountains of Wales.

Cochlearia officinalis, or Common Scurvy-graſs, has long been held in very high eſtimation as an antiſcorbutic and purifier of the blood. It has a ſomewhat unpleaſant ſmell, and a warm, bitter taſte. Its active matter is extracted by maceration both in watery and ſpirituous menſtrua, and accompanies the juice obtained by expreſſion. The moſt conſiderable part of it is of a very volatile kind; the peculiar penetrating pungency totally exhaling in the drying

* Linn. Woodw. Miſs. Withering. Lightf. Haller.

of

of the herb, and in the evaporation of the liquors. Its principal virtue reſides in an eſſential oil, ſeparable in a very ſmall quantity by diſtillation with water. Scurvy-graſs is antiſeptic, attenuant, aperient and diuretic, and is ſaid to open obſtructions of the viſcera and remoter glands, without heating or irritating the ſyſtem. It has been long conſidered as the moſt effectual of all the antiſcorbutic plants, of which we have the teſtimonies of the moſt celebrated phyſicians, and it has been obſerved that it naturally grows moſt in thoſe high latitudes where the ſcurvy is moſt prevalent. In rheumatic pains of long continuance, accompanied with fever, this plant, combined with Arum and Wood-ſorrel, is highly commended by Sydenham and Lewis. A remarkably volatile and pungent ſpirit, prepared from this herb, and called *Spiritus antiſcorbuticus*, was found by Werlhof to be a uſeful remedy in Palſy and other diſorders requiring an active ſtimulant, given in the doſe of thirty drops ſeveral times a day; but no preparation ſeems ſo beneficial by way of an antiſcorbutic as the freſh plant eaten as a ſalad, or its expreſſed juice drank. If the green herb be infuſed in ale or beer, and put into a bottle well corked, it will communicate to it all its antiſcorbutic virtue or volatile ſpirit in three or four days time. Mr. Ray from his own experience, recommends this ale to ſuch as are troubled with the ſcurvy, to be taken for their ordinary drink. He ſays that it is not ſo good if the Scurvy-graſs has been long infuſed in it; for thereby the earthy and fixed parts are forced from the herb, and communicated to the ale, and the volatile parts either fly away, or being jumbled with the more fixed parts, loſe a great deal of their virtue. The juice of ſcurvy-graſs with the bruiſed herb applied to the face has been recommended as a coſmetic, and ſhould be afterwards waſhed off with a decoction of bran.

2. Stem not branching. Runners procumbent. Both root and ſtem leaves haſtate or ovate, with an angle on both ſides of the baſe. Petiole not toothed or claſping at the baſe. Capſules ovate[b].

Mr. Lightfoot obſerves that the root-leaves are often rounded, as in the preceding, but they are ſmaller; the ſtalks are weak, and commonly trail upon the ground; the ſtem-leaves are haſtate, with an angle or dent on each ſide near the baſe, and ſtand on ſhort peduncles. He is diſpoſed to conſider this only as a variety, having obſerved the limits between it and the *officinalis* to vaniſh inſenſibly into one another.

Sea coaſts of Denmark, Sweden, and Britain, Portland, and about Plymouth. *Lobel.*—Wells in Norfolk. Iſle of Walney, Lancaſhire. Near Llanbadrick church, Angleſea, and in Scotland.

3. Leaves ſucculent, often reddiſh; all oval-lanceolate, many having no ſinuſes, but only ſuch an angle as Linneus deſcribes. Ray affirms that even the loweſt leaves are angular or indented. Dr. Stokes ſays that in his ſpecimens the root-leaves are oval and very entire; the ſtem-leaves ſlightly angular.—According to Mr. Woodward, the ſtem-leaves are arrow-ſhaped at the baſe and ſtem-claſping. Silicles roundiſh, fleſhy, much larger than in the firſt ſpecies, and terminated by a longer ſtyle[c]. —Mr. Hudſon doubts whether this may not be a variety of the firſt ſort. Mr. Woodward thinks it to be out of all doubt diſtinct from that; and affirms that at Yarmouth, where it grows abundantly, and elſewhere, it never appears to vary. Mr. Miller ſays that it flowers later in the ſeaſon.

Sea coaſt in muddy ſoils. Brims of the river Thames; Portſmouth, Briſtol, &c. *Ger.*—In the ſalt marſhes of Kent and Eſſex. Iſle of Wight. King's Weſton. Rocks of Inch Columb.

4. Root-leaves very ſmall, underneath very convex and fleſhy, veinleſs, very entire, on long petioles[d]. Stem-leaves haſtate, angular, on ſhort petioles. Not above two inches high. Only a ſtarved variety of the firſt ſort[e]. Mr. Hudſon alſo gives it as a variety: and Mr. Woodward thinks that this and the *officinalis* are certainly the ſame.]

Sea coaſts of Muſcovy and Davis's Straits. [Mountains of Caernarvonſhire, about Llanberys. Near Settle. On the highlands, and in the Orkneys.

Theſe three are ſaid to be biennial plants, whereas the firſt or common Scurvy-graſs is perennial. This ſeems ſcarcely probable.

5. Stems and leaves ſmooth, and lie flat upon the ground all round the root: the flowers grow in ſhort axillary tufts, are very ſmall, and have white petals[f].

Nectary of ſix glands, upright, green, blunt, as long as the anthers; four of them oblong, compreſſed, at the baſe of the petals; the other two cylindric, narrower, between the longer ſtamens. Anthers ſhed their duſt before the flower opens. Silicle kidney-heart-ſhaped, terminated by a ſhort conical ſtyle, depreſſed on the ſides, with furrows and ſharp ridges tending towards the edge, where they run out into ſharpiſh points: one of the cells not unfrequently empty, in which caſe the fertile ſeeds expand, filling up almoſt the whole of the ſeed-veſſel, and the ſtyle is bent down towards the empty cell. In this laſt reſpect it accords with *Myagrum*[g]. Lamarck regards the *Myagrum ſaxatile* as belonging to the genus *Cochlearia*. On the contrary the *Coronopus* recedes from the other ſpecies in its decumbent ſtems, pinnatifid leaves, glomerate flowers, and wrinkled creſted ſilicle.

By road-ſides, on rubbiſh, dunghills, &c. Annual; flowering from june to auguſt.

It is acrid, and taſtes like garden Creſs. The aſhes were an ingredient in Mrs. Stephens's once celebrated medicine for the ſtone[h].

6. Root perennial, creeping. Leaves very large, varying much, ſometimes deeply pinnatifid, ſometimes entire, and only crenated[i]. Flowering ſtem a foot or eighteen inches high, branching at top, almoſt naked. Flowers white, in looſe panicles. Silicle nearly ovate[k].—Sides of ditches, among rubbiſh, and in paſtures; flowering in may.

Horſe-radiſh is poſſeſſed of a volatile and pungent quality, which flies off in drying. It impregnates both water and ſpirit by infuſion or by diſtillation, very richly with its active matter. Horſe-radiſh is a moderate, ſtimulating, aperient, and antiſeptic medicine; it ſenſibly promotes perſpiration, urine, and the expectoration of viſcid phlegm, and excites appetite when the ſtomach is weakened or relaxed. It is principally uſed in paralytic and rheumatic complaints, in ſcurvies and impurities of the humors, in cachectic diſorders and in dropſies, particularly thoſe which follow intermitting fevers. Taken in conſiderable quantities, it provokes vomiting. Thomas Bartholin extols the virtues of horſe-radiſh in the ſtone from experience: he affirms that the juice of horſe-radiſh diſſolved a calculus or ſtony concretion that was taken out of a human body.

The ſcraped root is uſed for many culinary purpoſes. An infuſion of it in cold milk, makes one of the ſafeſt and beſt coſmetics.]

7. This ſort is a biennial plant, which uſually grows about a foot and a half high, with upright ſtalks; the flowers are produced in looſe ſpikes at the end of the branches; they are very ſmall, white, and are ſucceeded by ſhort oval pointed ſwelling pods, having no ſtyle at the end, and filled with round ſeeds. It flowers in may, and the ſeeds ripen in july and auguſt. [According to Linneus, it has the ſtature of Turritis.

Native of Germany, and the South of France. Flowering from may to july. Cultivated 1683, by Mr. James Sutherland[l].

8. Root perennial, ſtriking deep. Stems ſeveral, upright, round below, ſomewhat angular at top, herbaceous, annual, ſlightly villoſe, about a foot in

[b] Linn. [c] Woodw. Mſſ. [d] Lightf. [e] Ibid. [f] Stokes in Withering. [g] Lightf. [h] Ray. [i] Haller. [k] Hort. kew.

height. Branches ſtrike up from the axils of the upper leaves to the ſame height with the ſtem, ending in corymbed racemes, and all together forming a cloſe compound corymb. Proper peduncles ſlender. Leaves acute, with a very ſhort pile of hairs on both ſides and hoary, irregularly alternate. Calycine leaflets oblong, patulous, blunt, pale, half the length of the petals; which are white, very blunt, from a narrow claw ſpreading very much into an oblong lamina, and caducous. Siliclé cordate, ſubdidymous, acuminate with the ſtyle, ſmooth; having only a ſingle ſeed in each cell. Abundant about Vienna, even in the ſuburbs, flowering from may to july*. Alſo in ſeveral parts of Germany, Italy and France.]

PROPAGATION AND CULTURE.

1. This ſort is propagated in gardens for medicinal uſes, by ſowing the ſeeds in july, ſoon after they are ripe, in a moiſt ſhady ſpot of ground; and when the plants are come up, they ſhould be thinned, ſo as to be left at about four inches diſtance each way. The plants that are taken out may be tranſplanted into other ſhady borders, if there is occaſion for them, otherwiſe they may be hoed out (as is practiſed for Onions, Carrots, &c.) and at the ſame time all the weeds may be hoed down, ſo as to clear the plants entirely from them, that they may have room to grow ſtrong. In the ſpring theſe plants will be fit for uſe; and thoſe that are ſuffered to remain will run up to ſeed in may, and perfect their ſeeds in june. If this plant is ſown in the ſpring, the ſeeds ſeldom grow well; therefore the beſt time is ſoon after they are ripe. The plants rarely live after producing ſeeds, ſo that it ſhould be ſown every year, to have it for uſe.

The Sea Scurvy-graſs (n. 3) growing in ſalt marſhes, and being overflowed with ſea water almoſt every tide, can hardly be made to grow in a garden, or at moſt to laſt longer there than one year.

6. The Horſe-radiſh is propagated by cuttings or buds from the ſides of the old roots. The beſt ſeaſon for this work is in october or february; the former for dry lands, the latter for moiſt; the ground ſhould be trenched at leaſt two ſpits deep, or more, if it will allow of it. The manner of planting it is as follows: provide yourſelf with a good quantity of offsets, which ſhould have a bud upon their crowns, but it matters not how ſhort they are; therefore the upper part of the roots which are taken up for uſe, may be cut off about two inches long with the bud to it, which is eſteemed the beſt for planting. Then make a trench ten inches deep, in which you ſhould place the offsets at about four or five inches diſtance each way, with the bud upward, covering them up with the mould that was taken out of the trench: then proceed to a ſecond trench in like manner, and continue the ſame till the whole ſpot of ground is planted. After this, level the ſurface of the ground even, obſerving to keep it clear from weeds, until the plants are ſo far advanced, as to be ſtrong enough to overbear and keep them down. With this management the roots of the Horſe Radiſh will be long and ſtraight, and free from ſmall lateral roots, and the ſecond year after planting will be fit for uſe. 'Tis true, they may be taken up the firſt year, but then the roots will be but ſlender; therefore it is the better way to let them remain until the ſecond year. The ground in which this is planted ought to be very rich, otherwiſe the roots will make but a ſmall progreſs.

7, 8. Theſe may be propagated by ſeeds, which if ſown in autumn will more certainly ſucceed than in the ſpring.

DESCRIPTIONS, &c.

1. [This uſeful tree is common almoſt every where within the Tropics, and is cultivated in both Indies. It is ſuppoſed however to be originally a native of the Eaſt Indies, and is found in a wild ſtate in the Maldives and Ladrones, &c. as alſo in the iſlands of the South ſeas.

The roots are very ſlender, ſimple and flexile; they ariſe ſeparately from the bottom of the trunk, and ſpread in all directions; ſome running to a great depth, while others creep almoſt parallel to the ſurface [a].] The trees grow to a great height; their ſtems are compoſed of ſtrong fibres like network, which lie in ſeveral laminas over each other, out of which come the branches, or rather leaves, which grow twelve or fourteen feet long. The midrib has ſword-ſhaped leaflets, whoſe borders fold backward: the firſt leaves which puſh out from the nut when planted, are very different from thoſe which are afterward produced; for they are very broad, and have many folds in each: whereas the after leaves have a ſtrong midrib, twelve or fourteen feet long, on which the leaflets are placed alternately; theſe are from ſix to eight or nine inches long, and are almoſt triangular, having very ſharp points, and are very ſtiff. The flowers come out round the top of the trunk of the tree in large cluſters; they are incloſed in a large ſpathe or ſheath, and the nuts afterwards are formed in large cluſters, ten or twelve together.

[When all the parts of the flowers have gained a due degree of perfection, the ſpathe ſplits on the under ſide, from the bottom upwards, and expoſes the common bunch, with all its flowers, to the open air: moſt of theſe are males, and fall off gradually as the ſpathe withers, leaving the embryo fruit, which is generally fixed to the lower and ſtronger part of the ſtalk, to increaſe and ripen gradually [b].

This fruit is properly a berried Drupe, ſuperior, very large, ovate, rounded-three-cornered, umbilicate both ways, tawny or reddiſh, becoming finally of a very pale red or browniſh colour: the ſkin is thin and very tough, the ſubſtance under this inveſting the ſhell is extremely fibrous. The ſhell itſelf is of a bony ſubſtance, ovate-three-ſided and acuminate, marked with three raiſed ſpurious ſutures, and having three holes at the baſe cloſed with a black membrane; it is one-celled, valveleſs, and of a dark brown colour. The kernel adheres all round the inner wall of the ſhell, and the cavity is filled with a milky liquor [c].

The kernel in ſome nuts is near an inch thick, and the hollow contains about a pint of a ſweet, delicate, wholeſome, refreſhing liquor. While the nut is growing, all the inſide is full of this liquor; but as the nut grows towards maturity, the kernel begins to ſettle round the inſide of the ſhell, and is ſoft like cream; as the nut ripens, it increaſes in ſubſtance, and becomes hard. The ripe kernel is ſweet enough, but very hard to digeſt, therefore ſeldom eaten, unleſs by ſtrangers; but while it is young and ſoft like pap, ſome will eat it, ſcraping it out with a ſpoon, after they have drunk the liquor [d].

The liquor is very pleaſant, while the nuts are young; as they grow old, it becomes more ſharp and cooling, and far more agreeable to over-heated habits. The kernel is very nouriſhing, is much uſed in making ſoups, curries, &c. and may be ſubſtituted for almonds, in emulſions and apozems, where it can be had freſh [e]. A pure ſweet oil is extracted from it, fit both for the table and medicinal uſes: in the Society iſles they ſcent it with

[a] Browne. [b] Ibid. [c] Gærtner. [d] Dampier. [e] Browne.

Sandal wood and other perfumes, in order to anoint their hair and ſkin with it [f].

Beſide the liquor in the fruit, there is a ſort of wine drawn from the tree called Toddy, which looks like whey. It is ſweet and very pleaſant, but it is to be drunk within twenty-four hours after it is drawn, for afterwards it grows ſour. They who have a great many trees draw a ſpirit from the ſour wine, called *Arack*. It is alſo diſtilled from Rice, &c. but none is ſo much eſteemed for making punch, as this ſort made of Toddy, or the ſap of the Cocoa-nut Tree; but it muſt have a daſh of brandy to hearten it, becauſe this Arack is not ſtrong enough to make good punch of itſelf. This ſort of liquor is chiefly uſed about Goa; and therefore it has the name of Goa Arack [g].

In order to make Arack, the tree muſt be kept from bearing fruit: for this purpoſe, the ſprout which produces the nut, and which ſhoots every month, is cut, and jars faſtened to it to receive the liquor; or the body is bored, and a plug put into the orifice, which is occaſionally taken out when the liquor is wanted: this liquor is ſuffered to ferment, and is diſtilled into the ſpirit called Arack, which far exceeds what is drawn from Rice. If this liquor is expoſed to the ſun, it ſoon turns to vinegar [h].

The coat or huſk of the ſhell is compoſed of ſtrong fibres, and is two or three inches thick. With theſe fibres, after ſoaking them in water, they make ſail-cloth, cables and cordage even for their largeſt ſhips; as alſo oakam, and a variety of yarns, uſed in the conſtruction of ſhips, boats, houſes, &c. The ſhell ſerves for a variety of houſhold veſſels; and when theſe are worn out, they are burnt to make lamp-black for painting, &c [i].

The trunk is formed into gutters, and occaſionally employed for incloſing, and roofing out-houſes, and, being nailed cloſe, is ſo hardy as to reſiſt the weather for many years [k]. The Indians make boats, rafters, and the whole frames of their houſes from the body of this tree. The leaves are uſed for thatching them, and are wrought into mats, baſkets, and many other things for which oſiers are employed in Europe.

The tender ſhoots at the top afford a pleaſant green, or cabbage, but for this the tree is deſtroyed [l]. Cultivated 1739, in Chelſea garden [m].

2. *Univerſal ſpathe* an oblong cylinder, drawn to a point at each end, woody, ſmooth within, marked on the outſide with numerous woody parallel ribs, uniting towards the end it opens longitudinally, falls off after the burſting of the ſpadix, and is from four to ſix feet long. *Spadix* of the ſame length: branchlets very ſimple, a foot in length, very much crowded, ſparſe: bent down by its weight, one or two only in each palm have male flowers; the remaining ſix or eight have male and female flowers together. The *male ſpadix* has the flowers ſupported by a ſmall, ſubovate, rigid bracte: the proper perianth conſiſts of three very ſmall, oblong, flattiſh ſcales, ſubcoaleſcent at the baſe, almoſt upright: petals linear, inclining to columnar, drawn to a point at each end, ſix or eight lines long, bent in different ways above the middle, very white, ſucculent, ſlightly connected at the baſe, alternate with the calycine ſcales, ſmooth and even: filaments one third of the length of the corolla, inſerted into the receptacle, ſubcoaleſcent; anthers linear, the length of the filament, verſatile, bifid at the baſe, two-celled; pollen very white and ſmall, ſhaped like ſaw-duſt. Theſe male flowers fall off with the leaſt touch, making a great heap under the tree.—The *androgynous ſpadixes* have male flowers like the former, but more permanent: a few only are mixed with the females; but above, where there are no females, they are crowded cloſe together: petals thinner than the former; filaments ſhorter; anthers horned.—Female flowers crowded, imbricate, ſup-

[f] Forſter eſcul. [g] Dampier in his account of Guam. [h] Long's Jamaica 3. 738. [i] Ives's voyage to India. [k] Long. [l] Browne. [m] Hort. kew.

 ported

ported with a triple bracte, looser than the other, and very flat. Proper perianth none, unless the bracte or outer petals be taken for it: petals six, the three outer larger, ovate, concave, broad at the base, roundish, covering most of the inner part of the flower, more rude, cartilaginous; the three inner shorter, white, fleshy, thinner: Nectary corollaceous, tubular, very thin, one third of the length of the petals, surrounding the greater part of the germ, very white: Germ subacuminate, very smooth, the height of the inner petal: Stigmas three, longish, smooth on the outside, roughish on the inside, almost upright. *Drupe* obovate, one-celled, succulent, very smooth, having a point at the end, surrounded at the base with the hardened permanent corolla. *Nut* covered with a cartilaginous skin and fibrous pulp; when dry very hard, a little striated, convex on one side, almost flat on the other, oblong, somewhat acute at both ends, perforated at the base with three oblique holes. *Kernel* cartilaginous, very hard, but having the same taste as in the common Cocoa nut.

The pulp of the nut is very mucilaginous, and is used for fatting hogs. An oil or butter prepared from it is in constant use among the Indians in South America, both in food and medicine [a].

3. Root knotty, round, thicker than the trunk, short, horizontally bent in directly below the surface, creeping, and presently putting out another trunk, so as to make a thicket, whilst it fixes itself firmly in the soil by slender fibrous roots. Trunk erect, armed with very numerous prickles, and furnished with some semilacerate withering stipes; it is about an inch in diameter, and in open situations seldom exceeds twelve feet in height; in woods it grows somewhat higher. The bark is brownish. Leaves subfrondose, few, clasping at the base, and pinnate; rib prickly; leaflets ensiform, acuminate, shining, flat, very slightly folded back at the base, serrate-prickly, unarmed, or with a few prickles only on both sides, commonly alternate, sometimes opposite, inconstant in number. Spathes axillary, solitary, spreading, permanent a long time after the ripening of the fruits, so that two or three withered leaves are frequently seen below the frond, with a spathe and spadix in their axils. Flowers with a very slight tinge of yellow, and without scent [b]. Calyx sometimes three-leaved: leaflets lanceolate, acuminate, many times smaller than the petals. Corolla triquetrous, frequently three-parted almost to the base, like a three-petalled corolla [c]. Fruits dark purple, the size of a common Cherry, containing an acid juice, of which the Americans make a sort of wine: they are eatable, but not pleasant [d]. However, they furnish the wild hogs with abundance of food in Jamaica [e]. Gærtner describes them as roundish drupes, flatted a little; the skin coriaceous; the nut subglobular, of a stony consistence, very thick, roughened all over with little holes and tubercles, perforated by three holes in the middle of the circuit, striated in rays at their mouths: the two smaller holes are blind, but the third is pervious, and leads to the central cell. Seed conoid, lying down horizontally, tubercled; the embryo placed in a very prominent papilla at the base of the cone.

Canes are made of the trunk deprived of its bark; they are black, shining, jointed, and very light: the French call them *Cannes de Tobago*, and they are sometimes brought to Europe. From this use of them for walking canes Jacquin has named this Palm *Bactris*, απο του βακτρου [f]. The outward part is extremely hard and elastic, and looks much like whalebone; it is fit for bows and rammers [g].

Native of Carthagena in South America.

4. The great Macaw Tree has a trunk the thickness of the human body, rises to thirty feet in height, has an ash-coloured bark, and is very thick set with sharp black prickles, of different lengths, placed usually in rings. The pinnas of the fronds are very long, and the whole is thick set with prickles. The fruit is as large as a Crab, and of the same shape: under a green skin it has a thin succulent astringent pulp; and within that a nut full of a white sweet eatable kernel [h].

The fruit is thus more particularly described by Gærtner. It is globular, flatted a little, about an inch in diameter, terminated by three acuminate sessile stigmas, and retaining the six-leaved calyx at the base: skin thick, coriaceous: pulp fibrous, succulent, finely fungose and coriaceous, adhering to the nut; which is globular, subtenticular, of a stony substance, thick, one-celled, with three holes on the side, two of which are blind, and the third pervious. Seed single, subglobular, flattish or slightly depressed near the hole of the shell, netted all over with arched streaks, of a brown bay colour. It differs from the Cocoa in the horizontal situation of the embryo.

According to Jacquin, it differs from the other Cocoas in having a thicker trunk with fewer prickles, and the ribs prickly on both sides. But it is not certain that his C. aculeatus or *Grougrou* is the same with ours.

Browne says, that the husks both of this and the small Macaw-tree are full of oil, and the nut black and shining. The Negroes say that it yields the true Palm-oil. The outside of the trunk is made into laths, bows and darts.

It is common in the Caribbee islands: and was cultivated by Mr. Miller in 1731 [i].

5. This is a very thick Palm, only four feet high, frequently shorter, or even without any stem. Fronds fifteen feet long, almost upright, irregularly pinnate, with a subcylindric rachis or midrib. Leaflets four feet long, subulate-ensiform, with a long point; they are simply plaited, distant at the base, smooth, coriaceous. Flowers terminating, on a long erect thick branching bracted peduncle: the spadixes of the male lateral, round, reflex, covered all over with floscules; of the female, roundish, surrounded with floscules. Spathe none, except the bractes, which are subacute, short and distant. Drupe ovate-turbinate, compressed and lobed, having several grooves on it, and being three or four inches in length: skin fibrous thick smooth brown: shell bony roundish, two inches in diameter. It is supposed to be a different species from C. nucifera: the fronds and fruits agree, but the spadixes are different.

It is very frequent in salt-marshes, and at the muddy mouths of rivers in Cochinchina, Cambodia, the Philippine islands, the straits of Malacca, &c. [k]

PROPAGATION AND CULTURE.

1. This tree is propagated by planting the nuts in places where they are designed to remain; for it will not bear transplanting, unless the operation is performed while the trees are very young, for their roots shoot deep and wide; so that if these are cut or broken, the plants seldom survive it; which is generally the case with most of the Palms.

Where any persons are desirous of having a plant or two of this sort, they should procure some fresh nuts from the nearest place of their growth, which, on their arrival in England, should be buried in a warm bed of tanners bark, laying them on one side, that the young shoot which comes out from one of the three holes may not be injured by wet, covering them about six inches deep with the tan. In this situation, if the nuts are good, they will put out shoots in six weeks or two months, so should be then carefully taken up, and each planted in a separate pot filled with kitchen-garden earth, and plunged into the tan-bed in the stove, where the plants should always remain, for they are too tender to thrive in any other situation; but as the plants advance in their growth, they should be shifted into larger pots or tubs, being careful not to cut or tear their roots in the operation.

[a] Mutis in Linn. suppl. [b] Jacquin. [c] Swartz. [d] Jacquin. [e] Browne. [f] Jacquin. See Bactris minor. [g] Browne. [h] Sloane. [i] Hort. kew. [k] Loureiro.

Few of the nuts that are brought to England are ripe, being commonly gathered in an unripe ſtate, that they may keep during their paſſage. The beſt way to bring them for planting, is to put ſome that are fully ripe in dry ſand in a tub, where vermin cannot come to them. Theſe will often ſprout in their paſſage, which is an advantage, becauſe they may be immediately planted into pots of earth, and plunged into the bark-bed.

Theſe trees make conſiderable progreſs in the Weſt-Indies, but in Europe they are many years before they advance to any conſiderable height; the young leaves however being pretty large, they make a good appearance among other tender exotic plants in two or three years.

The other ſorts muſt be propagated by ſeeds in the ſame way. For the farther management of them ſee the article PHOENIX.

SPECIES.

1. Codon Royeni.

Lin. ſyſt. 397. *Reich.* 2. 264.

C. aculeatum. *Gærtn. fruct.* 2. 88.

DESCRIPTION, *&c.*

Stem herbaceous, firm, eighteen inches in height, round, with riſing branches. Leaves alternate, petioled, cordate-ovate, ſubrepand, undivided, acuminate, ſubcoriaceous, ſmooth, without veins on the upper ſurface. Flowers ſupra-axillary, ſolitary, peduncled, having the appearance of the corolla of *Atropa Belladonna*, whitiſh, with ten purple ſtreaks on the outſide. The whole herb is ſtriated †.

The fruit is a capſule, contained within the ſegments of the calyx, which are linear, keeled, converging and prickly; it is of an ovate-acuminate ſhape, terminated by the compreſſed forked ſtyle, and marked along both ſides with a ſharp ſuture; in other parts it is ſmooth; it has two valves, and within is divided into two cells: the partition is contrary to the valves, is cloven and ſpongy next the axis. Seeds numerous, ſmall, variouſly angular, of a ſhining blood-red, and covered with ſoft papillæ of the ſame colour ‡.

3. Coffea

3. Coffea racemosa.
Lour. cochinch. 145.
Very much branched, leaves rugged, racemes terminating.
4. Coffea Zanguebariæ.
Lour. cochinch. 145.
Corollas six-cleft, fruit angular-nerved.
5. Coffea guianensis.
Aublet. guian. 150. *t.* 57.
Flowers four-cleft, berries small violet-coloured, two-seeded.
6. Coffea paniculata.
Aublet. guian. 152. *t.* 58.
Branches quadrangular, leaves ovate-oblong, acute, corollas four-cleft, berries two-seeded.
7. Coffea sambucina.
Forst. flor. austral. n. 92.
Leaves oblong-lanceolate, acute, cymes corymbed, terminating.
8. Coffea opulina.
Forst. flor. austral. n. 93.
Leaves ovate-lanceolate, cymes contracted, globular, terminating.
9. Coffea odorata.
Forst. flor. austral. n. 94.
Leaves ovate, acute, cymes corymbed, axillary.
10. Coffea triflora.
Forst. flor. austral. n. 95.
Leaves ovate-lanceolate, acuminate, peduncles terminating three together, one-flowered.]

DESCRIPTIONS, *&c.*

1. The Coffee-tree seldom rises more than sixteen or eighteen feet high in its native country, or more than ten or twelve in Europe. The main stem grows upright, and is covered with a light brown bark. Branches horizontal, opposite, brachiate at every joint, [long, simple or undivided, slender, smooth, lax, and inclined to bend downwards;] the lower ones longest, the others gradually decreasing to the top, so as to form a pyramid. Leaves opposite, when fully grown four or five inches long, and an inch and half broad in the middle, ovate-lanceolate, the borders waved, the surface of a lucid green, [smooth, beneath paler. Petiole only two or three lines in length; from the sides of the midrib, which is a continuation of it, issue twenty or more secretory punctures. The leaves generally continue three years[a].] The flowers are produced in clusters (two to four) at the base of the leaves, sitting close to the branches: they are of a pure white, with a very grateful odour, but of short duration: they are succeeded by berries, which are first green, but turn red when fully grown, and change to black when ripe. [They are of an oblong spheroidal form, with a little circular area at the top, within which is a callous dot; the pulp is pale, insipid and gelatinous; within it is two-celled; and the partition is fleshy and vascular: this is the only receptacle, and penetrates the cleft of the seeds. In each cell is one seed only, of an elliptic form, convex on one side, flat on the other, with a longitudinal cleft, of a pale glaucous colour, loosely covered with an elastic, diaphanous aril, the substance of paper[b].

The liquor which we call Coffee, or Coffea, prepared from the berry of this tree, is said to have been drunk in Ethiopia from time immemorial[c].

The Galla, a wandering nation of Africa, in their incursions on Abyssinia, being obliged to traverse immense deserts, and being also desirous of falling on the Abyssinians without warning, that they may be encumbered as little as possible with baggage, carry nothing with them to eat, but Coffee roasted till it can be pulverized, and then mixed with butter into balls, and put into a leathern bag. One of these about the size of a billiard ball, keeps them, they say, in strength and spirits during a whole day's fatigue, better than a loaf of bread, or a meal of meat[d]. It was introduced into Aden in Arabia from Persia, by Gemaleddin, only about the middle of the fifteenth century. Not long after, it reached Mecca, Medina, &c. and Grand Cairo. Hence it continued its progress to Damascus and Aleppo, and in 1554 became known at Constantinople; being introduced there by two persons whose names were *Shems* and *Hekim*; one from Damascus, the other from Aleppo. Each of these men opened a public Coffee-house in that city.

It is not certain at what time the use of Coffee passed from Constantinople to the western parts of Europe; but it is probable that the Venetians, on account of the proximity of their dominions, and their great trade to the Levant, were the first acquainted with it; and Pietro della Valle, a Venetian, in a letter from Constantinople written in 1615, tells his friend, that upon his return he should bring with him some Coffee, which he believed was a thing unknown in his country.

M. Thevenot, the French traveller into the East, at his return in 1657, brought with him to Paris some Coffee for his own use. It was known some years sooner at Marseilles, namely in 1644. Monsr. Du Tour, who wrote on Coffee in 1685, says that the French knew nothing of it until 1645.—Monsr. La Roque, who published his journey into Arabia Felix in 1715, contends that his father, having been with Monsr. de la Haye, the French ambassador at Constantinople, did, when he returned to Marseilles in 1644, drink Coffee every day. He allows notwithstanding that Thevenot was the first who taught the French to drink it[e]. However, till the year 1660, it was drunk only by such as had been accustomed to it in the Levant: but that year some bales were imported from Egypt; and in 1671 a coffee-house was opened at Marseilles.

Before the year 1669, Coffee was not known at Paris, except at M. Thevenot's, and some of his friends. This year it was effectually introduced by Solyman Aga, ambassador from Sultan Mahomet IV.; and two years after Pascal, an Armenian, sold it publicly at the Foire St. Germain, and afterwards set up a coffee-house on the Quai de l'Ecole; but meeting with little encouragement, he left Paris, and came to London. However, not long after, spacious rooms were fitted up at Paris in an elegant manner, for selling Coffee and other refreshments; and in a short time the number of coffee-houses increased to three hundred.

The use of Coffee was introduced into London some years earlier: for in 1652, Mr. Daniel Edwards, a Turkey merchant, brought home with him a Ragusian Greek servant, whose name was Pasqua Rosee, and who understood the roasting and making of Coffee. This servant was the first who sold Coffee, and kept a house for this purpose in George yard, Lombard street. Or rather, according to Mr. Houghton, in a shed in the church-yard of St. Michael's Cornhill, which is now, says he, (1701) a scrivener's brave house. Mr. H. adds, that one Rastall, whom he knew, went to Leghorn in 1651, and there found a coffee-house: that he met Mr. Daniel Edwards there, with his Greek servant, and that Mr. E. was the first who brought the use of Coffee here, except it was the famous Dr. Harvey, who some say did frequently use it. Pasqua, being no freeman, the ale-sellers petitioned the Lord Mayor against him. This made Alderman Hodges, whose daughter Mr. E. married, join his coachman *Bowman*, who was free, Pasqua's partner. And thus Mr. Rastall found them in 1654. But Pasqua, for some misdemeanor, was forced to run the country, and Bowman by his trade, and a contribution of 1000 six-pences, turned the shed to a house. Bowman's apprentices were first John Painter, then Humphry, from whose wife Mr. H. had this account[f]. The first mention of Coffee in our statute books was in 1660. 12 Car. II. cap. 24[g].

In 1688, Mr. Ray affirms, that London might rival Grand Cairo, in the number of its Coffee houses, and that they were to be found not only in the capi-

[a] The passages between crotchets are from Linnæus's *hortus Cliffortianus*. [b] Gærtner. [c] Ellis. [d] *Bruce Abyss.* 2. 226. [e] Mosley. [f] Collections, 3. 125. [g] Ellis.

tal,

tal, but in every town of note in England. Probably the ill-judged proclamation of Charles II. in 1675 againſt Coffee-houſes, contributed much to eſtabliſh them.

The firſt European author who has made any mention of Coffee, is Rauwolff, who was in the Levant in 1573; but the firſt who has particularly deſcribed it is Proſper Alpinus, in his Medicina Ægyptiorum, 1591, and in his hiſtory of Egyptian plants, publiſhed at Venice in 1592.

Fauſtus Najronus Baineſius wrote the firſt treatiſe expreſsly on Coffee. It was printed at Rome in 1671, and intituled, *De ſaluberrima potione Cahu, ſeu Caſe, nuncupata*[b].

Two Engliſh travellers notice this beverage at the very beginning of the 17th century. Biddulph about 1603, and William Finch in 1607. The former ſays—"the Turks have for their moſt com-"mon drink *Coffa*, which is a black kind of drink, "made of a kind of pulſe like peas, called *Corva*." The latter, "that the people in the iſland of So-"cotora have, for their beſt entertainment, a China "diſh of *Cohu*, a black bitteriſh drink, made of a "berry like a bay berry, brought from Mecca, "ſupped off hot[i]."

Lord Bacon makes mention of it in 1624.

Mr. Ray, in his hiſtory of plants, publiſhed in 1688, ſpeaking of it as a drink very much in uſe, ſuppoſes that the Arabs deſtroyed the vegetable quality of the ſeeds, in order to confine their commodity within themſelves; and adds, that he wondered the neighbouring nations did not contrive to bring away ſome ſound ſeeds or living plants, in order to ſhare in ſo lucrative a trade.

This was ſoon done: for Nicholas Witſen, burgomaſter of Amſterdam, and governor of the Eaſt-India Company, deſired Van Hoorn, governor of Batavia, to procure from Mocha, in Arabia Felix, ſome berries of the Coffee-tree, to be ſown at Batavia: which he having accordingly done, and about the year 1690 having raiſed many plants from ſeeds, ſent one over to governor Witſen, who preſented it to the garden at Amſterdam: it there bore fruit, which in a ſhort time produced many young plants[k]. From theſe the Eaſt Indies, and moſt of the gardens in Europe have been furniſhed; and ſo early as the year 1696, the Coffee-tree was cultivated at Fulham by Biſhop Compton[l].

In 1714, the magiſtrates of Amſterdam preſented Louis XIV. with a Coffee-tree, which was ſent to the royal garden at Marly, under the care of M. de Juſſieu, who had written a memoir, printed in the hiſtory of the academy of ſciences for 1713, deſcribing the characters of the genus, with a figure of it, from a ſmaller tree, which he had received from M. Pancras, burgomaſter of Amſterdam, and director of the botanic garden there.

In 1718, the Dutch colony at Surinam began firſt to plant Coffee; and in 1722, M. de la Motte Aigron, governor of Cayenne, contrived by an artifice to bring away a plant from Surinam, which in the year 1725 had produced many thouſands.

Rochon in his account of Madagaſcar aſſerts, that in 1718, the inhabitants of the iſle of Bourbon ſent to Moka and Aden for ſome young plants of the Coffee-tree, which being cultivated with care, became in a few years very productive, and the iſland ſoon afforded the French Eaſt India Company a very important article of trade[m].

In 1727, the French, perceiving that this acquiſition might be of great advantage in their other colonies, conveyed ſome of the plants to Martinico. Monſ. Fuſee Aublet indeed affirms, that Monſ. Clieux carried the firſt Coffee plant to Martinico in 1720; and that the French Eaſt India Company ſent ſome plants to the iſle of Bourbon in 1717; that one plant only ſurvived, which bore fruit in 1720, and many were produced from it[n].

From Martinico it moſt probably ſpread to the neighbouring iſlands: for in the year 1732, it was cultivated in Jamaica, and an act was paſſed to encourage its growth in that iſland[o].

The firſt plant which appeared in Jamaica, was carried there by Sir Nicholas Laws, and placed in the garden of Townwell, at preſent called Temple Hall, the property of Mr. Lutterell. But he dying in 1731, did not ſee the cultivation of it make any conſiderable progreſs[p].

In the year 1752 the export of Coffee from Jamaica was rated at 60,000 pounds weight. In 1775 it was 440,000 pounds.

The Abbé Raynal ſays, that 12,550,000 pounds weight is annually exported from Arabia Felix[q].

Dr. Patrick Browne, who reſided many years in Jamaica, informs us that the Coffee-tree thrives beſt in a rich ſoil, and cool ſhaded ſituation, where it produces ſo great a quantity of fruit, that the branches can hardly ſuſtain the weight, and even the very trunk yields to the load. This fruit is large and ſucculent, and the berries lax and clammy: they are gathered when only half ripe; and inſtead of being ſtripped of their pulp, and the ſeeds being carried down to the low lands to be dried, they are left ſoaking in their clammy juices, to dry ſlowly in a damp air. This alone will ſufficiently account for the inferiority of the Jamaica Coffee to the Arabian, which grows in a ſandy, dry, hot ſoil, where the berries have but little pulp, and are ſoon dried, ſpread upon mats and expoſed to the ſun.

Dr. Browne however is of opinion that the Weſt India iſlands might furniſh Coffee equal in quality to the Turkey, if the following remarks were attended to.

1. New Coffee will never parch or mix well, from the natural clammineſs of the juices.

2. The ſmaller the grain, and the leſs pulp the berry has, the better the Coffee, and the ſooner it will parch, mix, and acquire a flavour.

3. The drier the ſoil, and the warmer the ſituation, the better the Coffee it produces will be.

4. The larger and more ſucculent the grain, the worſe it will be.

5. The worſt Coffee produced in America will, in a courſe of years, not exceeding ten or fourteen, be as good as the beſt we now have from Turkey; due care being taken to keep it in a dry place, and to preſerve it properly.

6. Small-grained Coffee, or that which is produced in a dry ſoil and warm ſituation, will in about three years be as good, as that which is commonly uſed in the coffee-houſes at London.

Theſe, the doctor tells us, are facts founded on repeated experiments.

Mr. Miller adviſes thoſe who cultivate the Coffee tree in the Weſt Indies, firſt, to make choice of a ſoil rather dry than moiſt. Secondly, to permit the berries to remain upon the trees, till the ſkin ſhrivels and turns black. Thirdly, to gather them, or rather ſhake them from the trees when they are perfectly dry, ſpreading them upon cloths or mats in the ſun to dry, as they do in Arabia Felix, carrying them every evening under cover; and when they are perfectly dry, deprived of their huſks and winnowed, to pack them up carefully in bags, and when they are ſhipped, not to ſend them with rum or other goods from which they may imbibe any diſagreeable flavour.

Dr. Browne recommends ſuch as poſſeſs large Coffee-walks to have a convenient platform to dry the ſeeds on; and he thinks it would be worth while to try whether ſweating would deſtroy the clammineſs of the large berries. They ſhould however be pulped and dried as ſoon as poſſible; then huſked and cleared from all the outward coverings. This is generally done in Jamaica by pounding the dried berries lightly in a large wooden mortar; they are then winnowed, cleared, expoſed afreſh to the ſun for ſome days, and then caſked for the market. If

[p] Moſeley.

it be not well dried, it is apt to heat on board ships, and then it loſes all its flavour [a].

Long, in his hiſtory of Jamaica (1774) obſerves that the berries ought never to be gathered until the pulp is exhaled, and the coat ſuffered to become thoroughly dry and ſhrivelled, ſo that they appear ready to drop off, and actually fall upon a ſlight touch. In confirmation of this, he affirms, that he has experienced the beſt flavoured Coffee to have been collected from under the trees, where it had recently fallen, quite dry, black and ſhrivelled. He adds, that the trees ſhould be planted at diſtances proportioned to their growth, which in the lowlands is five feet, in the mountains ten feet or more: and that the produce of a good tree is from one pound and a half to two pounds weight.

He thinks that the mountain Coffee might be improved by ſending the berries to the lowlands, where the heat is greater, and the air more dry; and by having a drying-houſe under a roof, with one or more platforms, admitting a free current of air, and excluding the rain and ſunſhine.

He informs us that the huſk is no longer beat off in mortars, but by rollers turned by mules, that wooden ones are preferable to ſtone or iron, and that the moſt approved machine, invented by Mr. Latham, will clean one hundred hogſheads in a day.

Dr. Fothergill ſuggeſts very reaſonably that the removal of the Coffee-tree from the dry, ſterile, ſandy ſoil of Arabia, into the rich deep ſtaple of Batavia, where the quantity of wet that falls in the rainy ſeaſon is exceſſive; its removal thence into Holland and France, and its tranſportation afterwards to a climate much more abounding with moiſture than that of which it was a native, may ſo far have altered the quality of the fruit, as that it may not be eaſily brought back to its original excellence. This however he thinks may be done, by making the plantations in ſoils as ſimilar to its natural one as poſſible. He alſo hints, that the fruit of young trees is in general more inſipid, or has a leſs refined taſte, than at a more advanced age; that probably this may be the caſe in the Coffee-tree; and he affirms that in old trees the fruit is ſmaller. The French, both in the Eaſt and Weſt Indies, cultivate Coffee with great attention, and accordingly theirs is much ſuperior to ours, and is even thought by ſome to be nearly equal to the beſt Turkey. They are alſo more careful in ſhipping it home, not mixing it, as we do, with cargoes of Rum and coarſe Sugars, which communicate a taſte ſcarcely to be driven off by fire. But it ought to be obſerved, that whilſt the induſtry and genius of the French Coffee planters have been cheriſhed; ours have been reſtricted by a duty, which leſſens the conſumption [b].

Dr. Fothergill alſo thinks it probable that our plantation Coffee is uſed too ſoon; and that one part of the excellence of the Mocha Coffee may ariſe from the intervention of between two and three years between its growth and conſumption. In confirmation of this, the doctor found that ſome raw Coffee which was ſent him from the Weſt Indies, and was ſo ill-taſted as to be unfit for uſe, being laid in a very dry cloſet, was tried again the year after, and found to be greatly amended. He therefore recommends the importing it without other goods; and the keeping it in dry, airy places, till ſuch a quantity is got together, as may be ſufficient to load a veſſel [c].

This ſcheme, ſays Mr. Miller, of keeping the American Coffee-berries ſeveral years, is contrary to all the experience I have had, and the information I can obtain from thoſe who have ſeen the whole management of Coffee in Arabia. Two gentlemen who had lived there ſome years aſſured me, that the berries, when firſt gathered, were much better than thoſe which are kept any time. And a curious gentleman who reſided in Barbadoes two years alſo told me, that he never drank better Coffee in any part of the world, than what he made from the freſh berries which he gathered himſelf, and roaſted as he had occaſion for them. This account is confirmed by trials with berries produced in our Engliſh flowers, which make a better flavoured liquor, than the beſt Arabian Coffee berries that can be procured in England.

[The difficulties attending the keeping Coffee any length of time to the planter are alſo apparent. His profit is not ſufficient to enable him to keep it ſo long as is propoſed: and a tree in a rich ſoil producing almoſt twice as much as one in a light one, whereas the difference in price in the European markets between ſmall well-prepared Coffee, and that which is of the worſt kind is only from fifteen to twenty *per cent.* the planters find their account in making their Coffee-walks in the richeſt ſoil; where alſo the trees laſt a much longer time. The dampneſs of the climate in the iſlands is ſuch, that it is very difficult to dry the berries well; and the negroes being lazy, ignorant, and frequently ill-diſpoſed, will not attend properly to the gathering of them perfectly ripe: beſides the ſeaſon for this being near the winter, the rains, which are then very frequent, often make the berries fall before they are perfectly ripe [d].]

It appears however that the Jamaica planters, after a multitude of experiments, and the moſt laudable exertions, have diſcovered the art of cultivating, picking and curing the berries, ſo as to make their Coffee equal to the growth of Arabia. Some ſamples have been produced, which were pronounced by the London dealers even ſuperior to the beſt brought from the Eaſt. Two of them were equal to the beſt Mocha Coffee; and two more were ſuperior to any that could be had at the grocer's ſhops in London, unleſs the price of *picked* Coffee be paid, which is two ſhillings the pound more than what they call the beſt Coffee. The other ſamples were little, if at all inferior to what the grocers call beſt Coffee [e].

The Coffee-tree having been tranſported to Europe, and to the poſſeſſions of Europeans both in the Eaſt and Weſt Indies from Arabia, has been commonly ſuppoſed to be indigenous of that country. It ſeems however, according to Mr. Bruce, to have been brought originally from the kingdom of Caffa, the ſouth province of Narea in Africa. It is the wood of the country, produced ſpontaneouſly every where in great abundance, from Caffa to the banks of the Nile. The foot of the mountains, or edge of the marſhes neareſt Narea, is thick overgrown with Coffee-trees, which if not the only, is the largeſt tree known there [f].

Coffee is named by the Perſians *Cahuat* and *Cohu*; by the Turks *Chauhe* and *Cahuey*; by the Arabians *Cachua*, *Caoua*, and *Cahouah*. The Egyptians call it *Eleave*.

2. The Weſtern Coffee-tree is upright branching, and ſix feet high. Leaves lanceolate-ovate, ending in a blunt point, quite entire, ſhining, petioled, oppoſite, only on the young twigs, four inches long. Stipules alternate with the petioles, ſubulate, acuminate, upright and oppoſite. Racemes trichotomous, ſometimes panicled, uſually terminating, but ſometimes axillary. Corolla white, very ſweet-ſcented.

Native of St. Domingo, about Cape Francois, where it flowers in december [g].

It is alſo pretty common in the lower woods of Jamaica. *Browne* names it the *wild Jeſſamine*, the flowers having much of the ſhape and ſmell of our white Jaſmin.

3. This is a ſmall tree, only four feet high, with many diffuſed round branches. Leaves ovate-lanceolate, quite entire, beſet with many tubercles, oppoſite, on ſhort petioles. Flowers ſubterminating, in erect brachiate racemes: the common pedunele long, quadrangular; the partial ſhorter, round, oppoſite

[g] Jacquin.

poſite or ſtellate. Berry roundiſh, ſmall, red, watery, one-celled with two hemiſpherical ſeeds[a].

It agrees with C. occidentalis of Linneus, and paniculata of Aublet in the panicle being brachiate; but it differs in having irregular branches, rugged tubercled leaves, and round berries with two ſeeds in them.

Native of the iſland of Mozambique.

4. This is a ſmall upright tree, ſix feet high, with thick ſhort ſpreading branches. Leaves ovate-lanceolate, ſmooth, oppoſite. Flowers white, axillary, ſeveral together, on ſhort one-flowered pedunculs; border ſix or ſeven-parted. Berries red, oblong-ovate, angular with longitudinal nerves, having two ſeeds.

Native of Africa on the coaſt of Zanguebar: and cultivated near Mozambique with the foregoing ſort[b].

5. Stem branching, from one to two feet in height; branchlets quadrangular, knotty. Leaves oppoſite, diſpoſed in form of a croſs, ſmooth, ſhining, entire, ovate-oblong, acute, on a very ſhort petiole. Stipule long, pointed, ſtiff: beneath which is a rib running down to the next joint. The largeſt leaves are two inches long, and nine lines wide. Flowers axillary, ſeveral together, ſmall and white. Calyx divided into four ſharp ſegments: corolla the ſame. Stamens four. Berry ſpherical, violet-coloured.

Native of Guiana, in the great foreſts of Orapu; flowering and fruiting in ſeptember.

6. Trunk ſeven or eight feet high, and five or ſix inches in diameter, covered with a gray, wrinkled, cloven bark. Boughs oppoſite, branched, knotty, quadrangular. Leaves oppoſite, diſpoſed in form of a croſs, entire, ſmooth, ſhining; the largeſt eight inches and a half long, three and a half broad; on a ſhort petiole. On each ſide between the two petioles at their baſe is a wide ſharp ſtipule, which is deciduous. Flowers terminating, panicled. Calyx four-toothed. Corolla white, four-parted, very ſweet-ſcented. Stamens four. Berry blueiſh, containing two ſeeds, one of which is frequently abortive.

Native of Guiana; flowering and fruiting in april[c].

7, 8, 9, 10. Theſe were found by our late circumnavigators in the iſlands of the South Seas. The 7th in the Friendly Iſlands; the 8th in New Caledonia; the 9th in Tanna and the Friendly Iſlands; and the 10th in Otaheite[d].]

PROPAGATION AND CULTURE.

As the Coffee-tree is an Evergreen, it makes a beautiful appearance at every ſeaſon in the ſtove, but particularly when it is in flower; and alſo when the berries are red, which is generally in the winter; as they continue a long time in that ſtate, there is ſcarce any plant that more deſerves a place in the ſtove than this.

It is propagated by the berries, which muſt be ſown ſoon after they are gathered from the trees, for if they are kept out of the ground a ſhort time they will not grow. I have frequently ſent the berries abroad by the poſt, but when they have been a fortnight in their journey they have all failed; and this has conſtantly happened every where, for the berries which were ſent from Holland to Paris did not grow, nor did thoſe which were ſent from Paris to England; ſo that wherever theſe trees are deſired, the young plants muſt be ſent, if it be at any diſtance from the place where they grow.

The berries ſhould be planted in ſmall pots, filled with light kitchen-garden earth, and plunged into a hot-bed of tanners-bark; they muſt be watered gently once or twice a week, but the earth muſt not be too moiſt, leſt it rot the berries. If the bed be of a proper temperature of warmth, the plants will appear in a month or five weeks time, and in about two months more will be fit to tranſplant. For as many of the berries will produce two plants, ſo the ſooner they are parted, the better their roots will be formed: for when they grow double till they have made large roots, they will be ſo intermixed and entangled, as to render it difficult to ſeparate them without tearing off their fibres, which will greatly prejudice the plants. When theſe are tranſplanted, they muſt be each put into a ſeparate ſmall pot, filled with the ſame earth as before, and plunged into the tan-bed again; which ſhould be ſtirred up to the bottom, and if required, ſome new tan ſhould be mixed with it, to renew the heat. Then the plants ſhould be gently watered, and the glaſſes of the hot-bed muſt be ſhaded every day till they have taken new root; after which the plants ſhould have free air admitted to them every day, in proportion to the warmth of the ſeaſon: during the ſummer they will require frequently to be refreſhed with water, but they muſt not have it in too great plenty: for if their roots are kept too moiſt, they are very ſubject to rot, then the leaves will ſoon decay and drop off, and the plants become naked; when this happens, they are ſeldom recovered again. The firſt ſign of theſe plants being diſordered, is, their leaves ſweating out a clammy juice, which attracts the ſmall inſects, that too frequently infeſt the plants in ſtoves; when they are not in health, theſe inſects cannot be deſtroyed, till the plants are recovered to vigour: for although the plants are ever ſo carefully waſhed and cleaned from them, yet they will be ſoon attacked by them again, if they are not recovered to health, for theſe inſects are never ſeen upon any of the plants while they are in perfect vigour; but when they are diſordered, they ſoon ſpread over all the leaves and tender parts of the plants, and multiply exceedingly; ſo that upon the firſt attack, the plants ſhould be ſhifted into freſh earth, and all poſſible care taken to recover them, without which all the waſhing and cleaning of the plants will be to little purpoſe. The diſorders attending the Coffee-trees, generally proceed from either being put into pots too large for them, nothing being of worſe conſequence than over potting them; or from the earth being too ſtiff, or from their being overhung by other plants, or being over watered. If theſe are properly taken care of, and the ſtove kept always in a proper temperature of heat, the plants will thrive, and produce plenty of fruit.

I have made trial of ſeveral compoſitions of earth for theſe plants, but have found none of them equal to that of a kitchen-garden, where the ſoil is naturally looſe, and not ſubject to bind; and if it has conſtantly been well wrought and properly dunged, this without any mixture is preferable to any other.

The plants ſhould not be too often tranſplanted, for that will greatly retard their growth. If they are new potted twice a year at moſt, it will be ſufficient; though unleſs the plants make great progreſs, they will not require to be removed oftener than once in a year, which ſhould be in ſummer, that they may have time to get good roots again before winter. During the warm weather in ſummer, theſe plants ſhould have a large ſhare of air, but they muſt not be wholly expoſed abroad at any ſeaſon; for although they may have the appearance of thriving in the open air during the heat of ſummer, yet when they are removed into the ſtove again, their leaves will fall off, and the plants will make but an indifferent appearance the following winter, if they ſhould ſurvive it: therefore it is the better method to keep them conſtantly in the ſtove, and admit a proportionable ſhare of air to them every day, according to the heat of the ſeaſon; they will require water two or three times a week in warm weather, but in the winter they muſt have it more ſparingly; and the ſtove in which they are placed, ſhould be kept to the heat aſſigned for the Ananas upon the botanical thermometers.

This tree has been propagated by cuttings, and alſo from layers; but theſe are long before they make roots, and the plants ſo raiſed, are never ſo ſtrong and thriving as thoſe which ariſe from berries;

[a] Lourciro. [b] Ibid. [c] Aublet. [d] Forſter.

ries; therefore where the berries can be procured, it is much the beſt method to propagate the plants by ſeeds.

When they are tranſplanted, their roots ſhould not be too much cut or trimmed; the decayed or rotten fibres ſhould be pruned off, and thoſe which are cloſely matted to the ſide of the pots ſhould be trimmed, but not cut too near to the ſtem; for the old fibres do not put out new roots very kindly, eſpecially thoſe which are become tough, ſo that there ſhould always be a ſufficient number of young fibres left to ſupport the plants, till new ones are produced.

The plants raiſed from the berries, produce fruit in two years from planting, and in hot climates ſooner; plantations of theſe trees may therefore be ſoon made in any of thoſe countries, where the temperature of the air is proper for their production, but the trees will not grow in the open air any where if there is a winter; ſo that in all countries without the tropics, they cannot be expected to grow abroad.

[In Arabia Felix the Coffee-tree is raiſed from ſeed, ſown in nurſeries, and planted out as there is occaſion. The plantations are in a moiſt ſhady ſituation, on a ſmall eminence, at the foot of the mountains, whence little rills of water are conducted in ſmall channels to the roots of the trees, to ſecure the production and ripening of the fruit. When they remove or tranſplant a tree, they make a trench three feet wide and five feet deep, which they line or cover with ſtones, that the water may the more readily ſink deep into the earth, and thus be kept from evaporating. When the fruit is nearly ripe the water is turned off, leſt the fruit ſhould be too ſucculent.

In places much expoſed to the ſouth, the Coffee-trees are planted in regular lines, ſheltered by a kind of Poplar tree, which affords a thick ſhade. Without this precaution they ſuppoſe that the bloſſoms would be ſo parched by the exceſſive heat of the ſun, as not to be ſucceeded by fruit.

COILANTHA. See *Gentiana*.

COILOPHYLLUM. See *Sarracenia*.

COILOTAPALUS. See *Ceeropia*.]

COIX. (Κοῖξ *is a name of Theophraſtus, one of his* καλαμοφυλλοι, *or reed-leaved plants, and allied to the Palms.*)

Lin. gen. n. 1043. *Reich.* 1135. *Schreb.* 1405. *Juſſ.* 34. Lacryma Job. *Tourn.* 306. Lithagroſtis. *Gærtn. t.* 1.

Claſſ. 21. 3. Monoecia Triandria.

Nat. order of *Graſſes*.

GENERIC CHARACTER.

* *Male flowers* diſpoſed in a looſe ſpike.

CAL. *Glume* two-flowered, two-valved; *valves* oblong-ovate, obtuſe, awnleſs, the outer thicker.

COR. two-valved; *valves* ovate-lanceolate, length of the calyx, very thin, awnleſs.

STAM. *Filaments* three, capillary. *Anthers* oblong, four-cornered.

* *Female flowers* fewer, at the baſe of the male ſpike, on the ſame plant.

CAL. *Glume* two-flowered, two-valved; *valves* rounded, thick, ſhining, hard; the outer larger; ſhining.

COR. *Glume* two-valved, outer valve ovate, larger; inner narrower, ſmaller: both awnleſs.

PIST. *Germ* ovate, very ſmall. *Style* ſhort, two-parted. *Stigmas* two, horned, longer than the flower, pubeſcent on every ſide.

PER. none; the outward calycine glume grows cloſely (to the ſeed,) increaſes, grows ſhining, falls, does not gape.

SEED ſolitary, roundiſh, covered by the oſſified calyx.

ESSENTIAL CHARACTER

MALES in remote ſpikes. *Cal.* Glume two-flowered, awnleſs. *Cor.* Glume awnleſs.

FEM. *Cal.* Glume two-flowered. *Cor.* Glume awnleſs. *Style* two-parted. *Seed* covered by the calyx oſſified.

   Lachryma Jobi paludoſa minor. *Burm. zeyl.* 138.
   Culm entirely ſimple, leaves ſmooth and even, ſeeds roundiſh.

DESCRIPTIONS, *&c.*

1. Culm ſix feet high, perennial, ſubcylindric, ſolid, jointed, erect, branched. Leaves lanceolate, quite entire, long, wrinkled underneath, reflex, claſping. Flowers axillary, on a long, ſlender, ſub-erect common peduncle: at the top many males in a ſubovate ſpikelet; and at the baſe a ſolitary female. The two ſtyles are capillary and entirely diſtinct, with long villoſe ſtigmas [a].

From the ſheaths of the upper leaves come out one or two peduncles, compreſſed, ſheathed at the baſe, ending at top in a coriaceous ovate involucre, hollow within, perforated at top, containing one (or two) covered ſeſſile female flowers, ſurrounded on one ſide with an exterior glumaceous valve, and having on the other a ſingle groove with two ſiſtuloſe cloſed appendicles: a ſtipe is put forth from the bottom of the involucre between the appendicles, ending in a ſhort few-flowered male ſpike. The involucre is permanent, hard, ſhining, ſmooth [b].

There is only a ſingle ſeed produced in each involucre, the other being conſtantly abortive: it is large, ſubglobular, gibboſe on one ſide, with a broad deep groove on the other, beaked at top with the permanent ſtyle, and having at bottom a black umbilical hole: the female involucre, which covers it and does not quit it, is thick, ſtony, ovate-conical, perforated at top and bottom, ſmooth, ſhining, of a livid or purpliſh colour [c].

Gærtner objects to the name of *Coix*, becauſe that is a ſort of Palm, or a plant nearly allied to the Palms, mentioned both by Theophraſtus and Pliny; he therefore changes it to *Lithagroſtis*.

Native of the Eaſt Indies. Cultivated in 1596, by Gerarde [d].]

2. This will grow to the height of ſeven or eight feet, whereas the foregoing is ſeldom ſo high as three feet in Europe; the ſtems become hard, like the Reed, or Indian Corn, they branch out, and produce ſeveral ſpikes of flowers. [Linneus ſays, this is perennial, and the foregoing ſpecies annual.

Native of America.

3. Culms three feet high, ceſpitoſe, quite ſimple, round, ſolid, jointed, ſmooth, riſing from a perennial, creeping root. Leaves lanceolate-linear, acuminate, quite entire, ſuberect, alternate, claſping. Peduncles long, erect, axillary, many-flowered: males and female from the ſame axil. Seed roundiſh, brown, ſhining, ſmall [e].

Native of Amboina, Ceylon, Cochinchina.]

PROPAGATION AND CULTURE.

1. Thoſe who are deſirous to cultivate this plant in England, may procure the ſeeds from Portugal, theſe ſhould be ſown on a moderate hot-bed in the ſpring, to bring the plants forward, and afterward

[a] Loureiro. [b] Juſſieu. [c] Gærtner. [d] Hort. kew. [e] Loureiro.

transplant them on a warm border, allowing each two feet room at leaſt, and when the plants have taken root, they will require no farther care, but to keep them clean from weeds. Theſe will flower about midſummer, and in warm ſeaſons, the ſeeds will ripen at michaelmas. There is a variety of this with much broader leaves, which I received from Smyrna ſome years paſt, which did not perfect ſeeds here, ſo I cannot ſay whether it is only a variety, or a different ſort from this.

2. This will not bear the open air in England, but muſt be plunged into the bark-bed, where it will flouriſh, and produce ripe ſeeds the ſecond year: it may be continued longer, if deſired.

COLCHICUM. *(So called from Colchis, a city of Armenia; where this plant is ſuppoſed to have been very common.)*

DESCRIPTIONS, *&c.*

1. This has a bulbous root, about the ſize and ſhape of the Tulip, but not ſo ſharp-pointed at the top, the ſkin or cover is alſo of a darker colour. Theſe bulbs are renewed every year, for thoſe which produce the flowers decay, and new roots are formed above. The flowers come out in autumn; theſe ariſe with long ſlender tubes from the root, about four inches high, ſhaped like thoſe of the Saffron, but larger; the number of flowers is generally in proportion to the ſize of the roots, from two to ſeven or eight: in march the green leaves appear, theſe are commonly four to a full grown root; they are folded over each other below, but ſpread open above ground, ſtanding croſs-ways: they are of a deep green, and when fully grown, are five or ſix inches long, and one and a half broad. The ſeed-veſſel comes out from between the leaves in april, and the ſeeds ripen in may, ſoon after which the leaves decay.

[With the other leaves one or two generally ariſe, of the ſame length, but only one-fourth of the width, which are a kind of bracteal leaves to the ſeed-bud. The ſeed-veſſel, which ariſes with the leaves, is ſeſſile at their baſe, large, ſomewhat ovate, but with three very blunt angles [a].

The ſeeds lie buried all winter within the bulb, in ſpring they grow up on a fruit-ſtalk, and are ripe about the time of hay harveſt. May not the very great length of the ſtyles account in ſome meaſure for the delay in the ripening of the ſeeds? As this plant bloſſoms late in the year; and probably would not have time to ripen its ſeeds before winter; providence has contrived its ſtructure ſuch, that it may be performed at a depth within the earth, out of the reach of the uſual effects of froſt: and as ſeeds buried at ſuch a depth are known not to vegetate, a no leſs admirable proviſion is made to raiſe them above the ſurface when they are perfected, and to ſow them at a proper ſeaſon [b].

Monſ. de Juſſieu entertains a ſingular opinion, that *Colchicum*, although it have the habit of *Crocus*, yet bears a nearer affinity to *Veratrum*. His accurate account however of its propagation by the root, may ſerve to explain that of bulbous plants in general, and alſo of the Orchideæ [c].

From the permanent ſtriated dilated tuber of the old root, ſituated on one ſide, and cloathed with the coats of the preceding root-leaves, a new plant ſprings from the ſide from the ſame coats, which is tuberous at the baſe, throws out fibres at bottom like other bulbs, and is received into the boſom of the former tuber which embraces it half round. This has an outer radical ſpathe, which is cylindric and tubular, cloven at top on one ſide, and half under ground. From two to ſix flowers half emerge from this ſpathe without leaves. In the mean time the fruits, much later than the flowers, ſit on the ſtem riſing out of the ſpathe. As the plant advances the new tuber increaſes, the old one, deprived of its nutriment, periſhes, and at the ſame time the former puſhes forth from its baſe the gem of a ſucceeding plant. There are commonly two lateral gems from the ſame tuber; one lower juſt deſcribed bearing the flower and ſeed; the other ſuperior, cauleſcent like the former, but more ſlender and ſcarcely floriferous [d].

It is a native of moſt parts of Europe.] Mr. Miller obſerved it in England, in great plenty, in the meadows near Caſtle-Bromwich in Warwickſhire, the beginning of ſeptember; and ſays that the country people call the flowers Naked Ladies, becauſe they come up without any leaves. [They give the ſame name to the Hepatica, and indifferently to any plant, which has flowers on naked ſcapes, appearing at a different time from the leaves.

It is found alſo with us in many other places; as near Derby and Northampton; Bury in Suffolk. Orchards on the borders of Malvern-chace, and meadows under Malvern-hills in Worceſterſhire—Meadows bordering the Severn, Worceſterſhire—Wallington and Hales Owen, Shropſhire—About Bath, Briſtol, Warminſter, Shepton-Mallet—Southgate.—Near Comb in Oxfordſhire, with a double flower, and ſome varieties of colour.—In Scotland, but not common.]

[a] Woodw. Miſ. [b] Withering. [c] Engl. bot. [d] Gen. p. 47.

The varieties moſt commonly propagated by the floriſts are the following:

The Meadow Saffron with white flowers.
Meadow Saffron with ſtriped flowers.
Broad-leaved Meadow Saffron.
Striped-leaved Meadow Saffron.
Many flowered Meadow Saffron.
Meadow Saffron with double purpliſh flowers.
Meadow Saffron with double white flowers.
Meadow Saffron with many white flowers.

[No cattle eat it. In a paſture where there were ſeveral horſes, and which was eaten down pretty bare, the graſs was cloſely cropped even under the leaves, but not a leaf of the Meadow Saffron was bitten[a].

This is one of thoſe plants which upon the concurrent teſtimony of ages has been condemned as poiſonous: but Dr. Storck of Vienna has taught us that it is an uſeful medicine. The roots have much acrimony. An infuſion of them in vinegar, formed into a ſyrup, by the addition of ſugar or honey, is found to be a very uſeful pectoral and diuretic. It ſeems in its virtues very much to reſemble Squill, but it is leſs nauſeous and acrimonious, though more ſedative[b].

Allioni relates, that he has experienced the Squill to be more ſafe and efficacious than the Meadow Saffron.]

2. This has a ſmaller root, with a darker coat. The leaves come up ſoon after the flowers decay, and continue green all the winter, like the Saffron; they are long, narrow, and ſpread on the ground: they decay in june. The flowers are of a reddiſh purple colour, and appear in auguſt and ſeptember.

[This flowers earlier than the common ſort; the root is globular, and the ſheathing leaves burſt forth with the flower. Theſe are at firſt broadiſh and ovate, then almoſt linear and a little ſhorter than the flower. The ſegments of this are lanceolate, purple marked with lines. Stamens half the length of the ſegments. Style very deeply trifid. The whole plant is little more than a finger's height[c].

Native of Spain and Portugal, Italy, the South of France and Switzerland. Cultivated here in 1629.

3. Leaves ſmaller than thoſe of the common ſort, for the moſt part three in number, and of a paler and freſher green colour, lying cloſe upon the ground, broad at the bottom, a little pointed at the end, waved about the edges. Root not ſo large as that of the common ſort. Flowers ſmaller, but very beautiful, whitiſh, with deep blue or purple ſpots. It flowers late, frequently not till october or november, and is ſomewhat tender[d].

Native of the Greek iſlands.

Cultivated (1629) by Parkinſon, Tuggie, &c. Alſo among Queen Henrietta Maria's flowers at Edgecombe in Surry, in the garden of Sir John Tunſtall, gentleman uſher to her Majeſty[e].]

PROPAGATION AND CULTURE.

Theſe are all very pretty varieties for a flower-garden, producing their flowers in autumn, when few other plants are in beauty. The leaves begin to decay in may; ſoon after which time, is the proper ſeaſon to tranſplant their roots; for if they are ſuffered to remain in the ground till auguſt, they will ſend forth freſh fibres; and after that it will be too late to remove them. The roots may be kept above ground until the beginning of auguſt; at which time, if they are not planted, they will produce their flowers as they lie out of the ground, but this will greatly weaken their roots. For the manner of planting their roots, ſee TULIPA. And for ſowing the ſeeds, ſee XIPHIUM.

Thoſe who are deſirous of obtaining varieties in the flowers muſt propagate them from ſeeds.

COLCHICUM. See *Bulbocodium*.

COLDENIA. *(So named by Linnæus, in honour of C. Colden, of North America: a very curious botaniſt who diſcovered ſeveral new plants: theſe are printed in the Upſal acts for* 1743.)

DESCRIPTION, *&c.*

1. This is an annual plant, whoſe branches trail on the ground, they extend near a foot from the root, and divide into many ſmaller branches. Leaves ſhort and ſeſſile, deeply crenate, have ſeveral longitudinal nerves, and are of a glaucous colour. Corolla cut into four ſegments at the top, of a pale blue colour, and very ſmall. The ſtigmas are hairy. Fruit compoſed of four cells, and wrapped up in the calyx; with a ſingle ſeed in each cell.

[Branches alternate. Leaves alternate, ſubpetioled, obovate, ſublunate on the upper ſide, plaited along the deep ſerratures, tomentoſe except in the plaits. Flowers axillary, few, ſeſſile. Seeds flat on the inner ſide, muricate and angular on the outer[f].

According to Gærtner, they conſiſt of four nuts, united into a rounded-four-cornered mucronate fruit: the rind fungous, very thick on the back, but becoming gradually thinner and almoſt membranaceous on the ſides: ſhells bony, hard, convex on one ſide, rounded; on the other ſide compreſſed into an acute angle; one-celled. Seeds ſolitary, ovate-acuminate, rufeſcent: they have only a ſingle, membranaceous, thin covering; the albumen is of the ſame form with the ſeed; the embryo is a little ſmaller and inverted; the cotyledons are doubled.

Native of the Eaſt Indies. Cultivated in 1759, by Mr. Miller.]

PROPAGATION AND CULTURE.

This plant is propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring; and when the plants are fit to remove, they ſhould be each put into a ſeparate ſmall pot, plunged into a hot-bed of tanners-bark, obſerving to ſhade them till they have taken freſh root; after which they ſhould have air admitted to them every day in proportion to the warmth of the ſeaſon, and gently watered two or three times a week in warm weather, but they muſt not have too much moiſture. Theſe plants muſt remain in the hot-bed, where they will flower in june, and the ſeeds will ripen in ſeptember.

COLETTA-VERTLA. See *Barleria*.

of botanical ſtudies, and the firſt who introduced this plant, among many others, to the Engliſh gardens. Miller.)

Lin. gen. 40. *Reich.* 43. *Schreb.* 51. *Gærtn.* 66. *Juſſ.* 112.

Claſſ. 2. 1. Diandria Monogynia.

Nat. order of *Perſonatæ? Labiatæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, two-lipped; *upper lip* three-cleft, reflex, wider; *lower lip* two-parted, more erect, ſubulate; permanent.

COR. one-petalled, unequal, (ringent, *G.*) *Tube* funnel-form, many times longer than the calyx. *Borders* five-cleft; *upper diviſions* obtuſe, very ſhort; the two upper ones reflex. *Lower lip* longer, many-cleft, capillary.

STAM. *Filaments* two, briſtle-form, erect, very long. *Anthers* ſimple, incumbent, compreſſed, obtuſe.

PIST. *Germ* four-cleft, obtuſe, with a larger glandule lying below the germ. (Germs four, *G.*) *Style* briſtle-form, length of the ſtamens, inclined to one ſide. *Stigma* bifid, acute.

PER. none. Calyx cheriſhes the ſeed in its bottom, and is ringent with an irregular mouth.

SEED ſingle, globoſe.

OBS. *The quaternary number of ſeeds ſeems to be the natural one from the germs, though one only grown to ripeneſs.*

ESSENTIAL CHARACTER.

Cor. unequal. *Cal.* of the fruit one-leafed, toothed—of the flower bifid. *Seed* one under the calyx of the flower.

SPECIES.

1. Collinſonia canadenſis. *Nettle-leaved Collinſonia.*
Lin. ſpec. 39. *Reich.* 73. *hort. cliff.* 14. *t.* 5. *mat. med.* 40. *Cold. nov.* 8. *Kalm. it.* 2. 317. *ed. angl.* 1. 197. *Ait. hort. kew.* 1. 47. *Gærtn. fruct.* 317. *t.* 66. *Pluck. ic. t.* 24.
Leaves ovate, both they and the ſtems ſmooth.

[2. Collinſonia ſcabriuſcula. *Rough-ſtalked Collinſonia.*
Ait. hort. kew. 1. 47.
Leaves ovate ſubcordate ſomewhat hairy, ſtem ſomewhat hairy ſcabrous.]

DESCRIPTIONS, *&c.*

1. This has a perennial root. In America it uſually riſes to the height of four or five feet, but in England it ſeldom grows above three feet high. The ſtalks decay in the autumn, and freſh ſhoots come out in the ſpring. The ſtalks are ſquare, with heart-ſhaped leaves, oppoſite, and ſerrate. The flowers are produced at the extremity of the ſtalks in looſe ſpikes; they are of a purpliſh yellow, and appear in july; the ſeeds ripen in autumn.

[One ſeed only generally comes to maturity, the others being almoſt always abortive; this is globoſe, aſh-coloured obſcurely reticulated with duſky veins *.

Native of North America, in Penſylvania and that latitude, in little woods and among buſhes, in a rich ſoil; not farther to the ſouth, nor to the north above 43° 15′. Mr. Bartram was the firſt who diſcovered it, and ſent it to Europe. It has a peculiar ſcent, which is agreeable, but very ſtrong. It is reputed to be an excellent remedy againſt pains in the limbs and a cold, if the parts affected be rubbed with it: a decoction of it is alſo ſaid to have cured the bite of the rattle-ſnake. In New York, *&c.* they call it *Horſeweed*, becauſe the horſes eat it in the ſpring, before any other plant comes up *.

Introduced 1735, by Peter Collinſon *.

2. Native of Eaſt Florida. Found there by Mr. John Bartram. Cultivated 1776, by John Fothergill, M.D. Perennial *.]

PROPAGATION AND CULTURE.

1. This plant may be eaſily propagated by parting the roots in october. Theſe roots ſhould be planted at three feet diſtance, for they require much nouriſhment, otherwiſe they will not thrive. It will live in the open ground, if it is planted in a ſheltered ſituation. But unleſs it is kept warm, and is duly watered, it rarely flowers well: therefore many perſons keep the plants in large pots: but theſe ſeldom produce good ſeeds; whereas thoſe which are planted in the full ground, and are conſtantly watered, will ripen ſeeds very well in good ſeaſons.

[2. This ſpecies is more tender, and requires the protection of the green-houſe. It may be increaſed in the ſame manner with the other.

Leaves ovate acuminate ſerrate roughly hairy on the upper ſurface, calycine leaflets toothletted lanceolate; they and the corollas hirſute, the upper lip bifid.

4. Columnea hiſpida.
Swartz prodr. 94.
Leaves ovate obtuſe toothletted hiſpid-hirſute, leaflets of the calyx lanceolate entire hairy, ſtem hairy rugged.

5. Columnea rutilans.
Swartz prodr. 94.
Leaves ovate-lanceolate villoſe toothletted, leaves of the calyx jagged, corollas villoſe, the upper lip two-parted.

6. Columnea ſtellata.
Linn. cochinch. 384.
Leaves ſtellate, flowers ſolitary, ſtem creeping.

DESCRIPTIONS, *&c.*

1. Stem ſcandent, rooting, angular, ſubquadrangular, ſtriated, ſucculent, brittle, ſomewhat hirſute. Leaves

* Gærtner. * Kalm. * Hort. kew. * Ibid.

Leaves petioled, oppoſite, ſmall, ſcarcely nerved. Flowers peduncled, ſolitary, axillary, blood-red, ſomewhat villoſe. Calyx ſubpentaphyllous. Tube of the corolla elongated, curved inwards: upper lip three-parted; the middle ſegment large, half-vaulted, entire; the two ſide ones broad-lanceolate, blunt, ſhorter, ſpreading: lower lip more deeply divided, lanceolate, obtuſe, ſpreading. Filaments the length of the corolla, two ſhorter: anthers ſquare, connected above the ſtigma. Capſule white, ſoftiſh, one-celled, reſembling a berry, but opening. Seeds neſtling.

Native of the Caribbee iſlands, Martinico, and Guiana, in moiſt parts of woods at the foot of the mountains. It is ſubparaſitical[a].]

Mr. Miller received ſeeds of this plant with ſcarlet flowers from Carthagena in New Spain.

β. The Columnea with a yellowiſh flower is only a ſeminal variation.

[2. Stem herbaceous. Leaves oppoſite, ſeſſile. Racemes terminating, elongated, ſtraight, with the flowers oppoſite. Calyx five-leaved, ovate. Corolla irregular; upper lip more oblong, lower three-cleft. Stamens twin; anthers parted at the baſe, with divaricated lobes, faſtened together ſo as to form a croſs. Style the length of the ſtamens. Capſules ovate, two-valved. Receptacle of the ſeeds globular, in which very many of the ſeeds are immerſed[b].

Stem erect, two feet high, four-cornered, the thickneſs of an eagle's quill, ſmooth. Branches axillary, quite ſimple, oppoſite. Leaves three inches long, ſubſeſſile, the upper ſurface rugged backwards, the under ſmooth and paler. Flowers in a raceme, all except the loweſt axillary ones oppoſite, ſolitary, ſpreading; the floral leaves lanceolate, quite entire[c].

Vahl has made this a ſeparate genus, adopting Browne's name of *Achimenes*. It differs from *Columnea* in having the corolla almoſt regular, not ringent: from *Seſamum* in having a two-celled capſule.

Native of the Eaſt Indies.

3. This beautiful vegetable is a native of the cooler mountains of Jamaica. It is very ſucculent, and grows luxuriantly in every rich and ſhady ſoil; throwing its branches frequently to the height of four or five feet, and higher, when ſupported. The ſtem is pretty thick: the leaves oppoſite and alternately larger. The flowers are large, beautifully variegated, and hairy on the outſide, like the other parts of the plant. The diviſions of the calyx are pinnated, ſomewhat like thoſe of the garden roſe. It has an uncommon appearance, and deſerves to be cultivated[d].

Introduced 1780, by the Marquis of Rockingham. It flowers in november[e].

4, 5. Natives of Jamaica[f].

6. Stem herbaceous, perennial, creeping, round, ſlender, whitiſh; branches ſuberect, four inches long, very tender. Leaves ovate, three lines long, ſerrate, ſtellate in threes, pale green, odoriferous, petioled. Flowers white ſtriped with red, hirſute, axillary, peduncled. Tube of the corolla ſcarcely gibbous; upper lip arched and trifid, lower biſid. Filaments curved inwards by pairs: anthers ovate, connected, ſeparable with difficulty. Capſule ſubulate, two-celled. The whole, except the capſule, hairy. It is an aquatic plant, of a very pleaſant appearance and ſmell, and being emollient and cooling, is uſed as a waſh by the women.

Native of Cochinchina, and cultivated there in pots and tubs filled with water, having earth at the bottom[g].]

PROPAGATION AND CULTURE.

All theſe plants being natives of hot countries, and moſt of them of the Weſt Indies, are too tender to live in England, out of a ſtove.

They are propagated by ſeeds ſown in a good hot-bed; and when the plants come up, they muſt be treated in the ſame way as other tender exotic plants which are kept in the bark-ſtove.

[COLUPPA. See *Plecebrum*.]

COLUTEA. (κολουτία, *Theophraſti*: *derivation uncertain*.) *Lin. gen. n.* 880. *Reich.* 954. *Schreb.* 1196. *Gærtn. t.* 154. *Tourn.* 381. *Juſſ.* 359.

Shrubby; leaflets ovate, emarginate; legumes oblong compressed acuminate.

9. Colutea procumbens.
Mill. dict. n. 7.
Stems trailing; leaflets ovate-oblong tomentose; flowers axillary on very long peduncles.

DESCRIPTIONS, *&c.*

[Most of the Coluteas are shrubs, with pinnate leaves, and stipules distinct from the petiole. Peduncles sometimes two-flowered, but more frequently many-flowered in spikes, both axillary and terminating. They are in general easily distinguished by their membranaceous inflated pod. Lamarck refers *Phaca australis* and *alpina* of Linneus to this genus, both having the pod one-celled [a].]

1. This has several woody stems, which grow to the height of twelve or fourteen feet, sending out many woody branches, with winged leaves, composed of four or five pairs of oval lobes, placed opposite, terminated by an odd one; these are indented at the top in form of a heart, and are of a grayish colour. The flowers come out from the wings of the leaves upon slender peduncles about two inches long, each sustaining two or three yellow flowers, whose standard is reflexed and large, with a dark-coloured mark on it. [Racemes shorter than the leaf; flowers from five to seven; calyx as thick as it is long; keel obtuse longer than the wings; style bearded on the inside; stigma bent down [b]. Legume membranaceous, subtransparent, semiovate, inflated, ending at bottom in a longish peduncle, at top in a short point. Seeds as far as twenty, or even more [c].

South of France, Italy, warmer parts of Switzerland, Carniola. Mr. Ray observed it about Montpellier, and in many parts of Italy, especially on mount Vesuvius even in the ascent to the crater, where there were scarcely any other plants. It flowers with us from june to auguſt.

The leaves are recommended as answering all the purposes of Senna, and Allioni has given particular directions for the preparation of them. A larger dose seems to be required to produce the same effect. The seeds, in a quantity of a dram or two, excite vomiting. It is said to afford food grateful to cattle [d].

Cultivated in 1570 [e].]

2. This has a woody stem, which sends out many branches on every side, and do not rise above seven or eight feet high; these are not so strong as those of the first sort, and the leaves are composed of five or six pairs of small heart-shaped leaflets, terminated by an odd one. The flowers proceed from the side of the branches, standing upon peduncles, each sustaining two or three flowers, shaped like those of the first sort, but smaller; they are of a dark red colour, marked with yellow; appear in june, and the seeds ripen in autumn.

[The Oriental Bladder-Senna, besides that it is never arborescent, differs from the foregoing sort in the shape, size, and number of the leaflets, which are quite smooth, glaucous, and more fleshy; on very short petioles or even subsessile: with scarcely conspicuous stipules. The corolla is not only of a different colour and smaller, but the wings are perceptibly shorter than the keel, whereas in the common sort they are nearly equal; the keel also is erect, and cut off at the end; and the marks on the standard are very different. The legume opens below the tip into a wide oval hole.

[a] Jussieu. [b] Scopoli. [c] Gaertner. [d] Haller and Ray. [e] Hort. kew. from Lobel.

It was discovered by Tournefort in the Levant.—Cultivated 1731, by Mr. Miller [f].]

3. This shrub seldom grows more than six or seven feet high, in this country. The branches are very slender, and much more pliant than those of the common sort, and therefore it grows less erect. The leaves are composed of nine pairs of leaflets, and are much smaller. The flowers are of a brighter yellow, appear a month earlier than in the common sort, and there is a succession of them till late in the autumn, which renders this much more valuable; and the branches not shooting so luxuriantly, nor so upright, this is in less danger of being broken by strong winds in summer.—Native of the Levant. The seeds were brought to England first by the Rev. Dr. Pocock, who gathered them in Turkey. Dr. Russel, who resided many years at Aleppo, reports that this shrub is very common about that city.

[Cultivated 1752, by Mr. Miller [g].]

4. A hoary shrub, with tomentose leaflets, smooth on the upper surface. Standard of the corolla shorter than the keel; wings very minute [h].]

Height from two to four feet; in favourable seasons and in a warm situation, plants of three years standing will be six feet high, with large heads, and all the branches covered with flowers, making a very fine appearance. Those plants however which are exposed to the open air seldom are of longer duration than two years, and are generally destroyed in severe winters: but they make much stronger plants while they last, and produce a greater number of flowers than those which are housed; these being of a fine scarlet colour, intermixed with the silvery leaves, afford an agreeable variety.—The stem is weak; the side branches grow erect; and the leaves have ten or twelve pairs of leaflets. The peduncles are axillary, towards the upper part of the stem, and sustain three or four flowers; these are very long, and not reflex. The legumes are very large. It flowers in june; but when the seeds are sown forward in the spring, they will produce flowers in auguſt, and sometimes perfect seeds in october [i].

[It is a native of the Cape of Good Hope, and was cultivated in 1683, by Mr. James Sutherland [k]. It was not however generally known in our gardens till the time of Miller.

5. The whole of this plant is slightly pubescent. Root perennial. Stems erect, round, striated, pale green, annual, quite simple or with almost barren branchlets. Leaves alternate, frequent, spreading; leaflets from six to eight pairs, blunt, on very short petioles, quite entire. Racemes axillary, solitary, simple, erect, longer than the leaves. Flowers small and without scent. Calyx pubescent on the outside. Corolla flesh-coloured: standard wide, roundish, emarginate, spreading very much, marked with deep purple streaks; wings shorter than the keel, blunt and oblong; keel dark purple, ascending at the end, almost as long as the standard. Style smooth; stigma blunt, with white villose hairs, but bearded only at the tip. Legume ovate-roundish, acuminate at both ends, compressed-flat, little inflated, smooth, membranaceous-subpellucid, not opening of itself. Seeds very few, compressed and black [l].

Native of Africa. Introduced in 1776, by Jos. Nich. de Jacquin, M. D.—It flowers in auguſt [m].

6. Annual, seldom perennial in the stem, smooth. Corollas dark blood red, with a striated standard, the length of the wings and keel. Legumes compressed [n], small, membranaceous, very thin, ovate, pedicelled, obliquely mucronate. Seeds two or four, rather large, compressed, of a dirty chestnut colour [o].]

Stem a foot and half high and slender, dividing at top into three or four branches. Leaflets five or six pairs, very narrow, an inch long, a little hoary. Flowers small, three together, on slender peduncles; appearing in july. The seeds ripen in autumn.

Native of the Cape of Good Hope.

[Cultivated 1731, by Mr. Miller [p].]

[f] Hort. kew. [g] Ibid. [h] Linn. spec. [i] Mill. dict. and fig. [k] Hort. kew. [l] Jacquin. [m] Hort. kew. [n] Linn. spec. [o] Gaertner. [p] Hort. kew.

7. Stems angular, ſtriated, fiſtulous, flowering the ſecond year. Stipules narrow, acuminate, ſubfalcate. Leaflets from ſeven to ſeventeen, nearly oppoſite, ſcarcely emarginate, ending with a ſmall point, quite entire. Peduncles axillary, elongated, racemed, many-flowered, pubeſcent, with ſmall ſubulate bractes. Calyx pubeſcent: corollas ſmall, whitiſh or red, with blood-red ſtreaks. Style naked; ſtigma pubeſcent, toothletted. Legumes compreſſed, ovate[5]. It was ſent to Retzius under the title of *C. herbacea*, of which he affirms there are ſeveral ſpecies.]

8. The eighth ſort was ſent me from La Vera Cruz, in New Spain, in the year 1730, by Dr. Houſtoun. This has a ſhrubby ſtalk, which riſes to the height of twelve or fourteen feet, ſending out many branches; the leaves are compoſed of three pairs of oval leaflets, terminated by an odd one; theſe are indented at the top, and are of a light green. The flowers are of a bright yellow, and ſtand two or three upon each peduncle, and are ſucceeded by compreſſed winged pods near four inches long, which end in long points.

9. This has many ſlender woody ſtems, which trail on the ground, and are divided into many ſmaller branches; the leaves are compoſed of twelve or fourteen pairs of ſmall, narrow, oval leaflets, terminated by an odd one; theſe, and alſo the ſtalks, are covered with a whitiſh down. The flowers are very ſmall, of a purple colour, and ſtand upon very long ſlender peduncles, each ſuſtaining three or four flowers; theſe are ſucceeded by compreſſed pods little more than half an inch long, which are a little bent like a ſickle, each containing a ſingle row of ſmall kidney-ſhaped ſeeds. It flowers in june and july, and the ſeeds ripen in autumn. This is a perennial plant, which, if ſheltered in the winter, will continue ſeveral years; but the branches do not extend more than a foot in length; and unleſs they are ſupported, always trail upon the ground.

The ſeeds were ſent to Mr. Miller from the Cape of Good Hope in 1753.

PROPAGATION AND CULTURE.

1, 2, 3. The three firſt mentioned ſorts are very hardy ſhrubs, which thrive in the open air extremely well, and are generally propagated for ſale in the nurſery-gardens; but the firſt ſort having been longer in England, is more generally known and propagated than either of the other, which have been but few years in the Engliſh gardens, nor had the third ſort been long known in this country in Mr. Miller's time; but as the ſeeds ripen here very well, it is now in as great plenty as the firſt ſort.

Theſe are all propagated by ſowing their ſeeds any time in the ſpring, in a bed of common earth; and when the plants are come up, they muſt be kept clear from weeds; and the Michaelmas following they ſhould be tranſplanted either into nurſery rows, or in the places where they are deſigned to remain; for if they are let grow in the ſeed-bed too long, they are very ſubject to have downright tap-roots, which render them unfit for tranſplantation; nor ſhould theſe trees be ſuffered to remain too long in the nurſery before they are tranſplanted, where they are to remain for the ſame reaſon.

The firſt ſort growing to the height of twelve or fifteen feet, is very proper to intermix with trees of a middling growth in wilderneſs quarters; or in clumps of flowering trees, where the oddneſs of their flowers and pods will make a pretty variety, eſpecially as theſe trees continue a long time in flower; for they uſually begin flowering by the end of may, and from that time to ſeptember they are ſeldom deſtitute of flowers, but eſpecially the ſecond ſort.

Theſe ſhrubs make great ſhoots annually, which are frequently broken down by ſtrong winds in the ſummer; ſo that if they are not ſheltered by other trees, their branches ſhould be ſupported, otherwiſe they will be broken and ſplit off, whereby the trees will be rendered unſightly.

The third ſort does not grow ſo tall as the common, but makes a more regular ſhrub, and is leſs liable to ſplit. The flowers of this ſort being of a duſky red colour, ſpotted with yellow, it makes a very pretty variety, and is as hardy as the common ſort, therefore may be propagated by ſeeds in the ſame manner.

[Mr. Curtis has learned by experience, that a very wet ſoil proves fatal to the common Bladder-Senna.—The ear-wigs finding a commodious retreat within the bladders, are great deſtroyers of the ſeeds: Mr. Miller therefore recommends the hanging lobſter-claws, or bowls of tobacco pipes on the ſhrubs, to entice theſe inſects[6].

The third ſort ſends forth many ſuckers, by which alſo it may be propagated; but the plants thus raiſed never grow ſo ſtrong, and are ſubject to produce many ſuckers[7].

4. The fourth ſort is tender, and will not live through the winters, when they are ſevere, in the open air in England; but in mild winters, if it be planted in a dry ſoil, and a warm ſituation, it will thrive very well; and thoſe plants which live abroad will flower much ſtronger, and make a finer appearance than thoſe which are preſerved in the green-houſe; for theſe plants require a large ſhare of air, otherwiſe they are apt to draw up weak, and not to produce their flowers in plenty; therefore when any of the plants are ſheltered in winter, they muſt be placed as near the window as poſſible, that they may have all the advantages of air; and in the ſpring they muſt be hardened, to bear the open air as ſoon as poſſible.

This ſort is propagated by ſeeds as the former. If the ſeeds are ſown early in the ſpring upon a warm border of light earth, the plants will flower in auguſt; and, if the autumn proves favourable, they will ſometimes ripen their ſeeds very well; but there are ſome perſons who ſow the ſeeds upon a moderate hot-bed in the ſpring, whereby they bring their plants ſo forward as to flower in july, whereby the ſeeds are generally perfected from theſe plants. When the plants are tranſplanted, it ſhould always be done while they are young, for they do not bear removing when they are large. This ſort will ſometimes live in the open air for three or four years, when the plants ſtand in a well ſheltered ſituation; and theſe will grow to have large heads, and make a very fine appearance when they are in flower; they will alſo continue much longer in beauty than thoſe plants which are treated more tenderly.

6. The ſixth ſort is a low annual plant, which ſeldom grows more than a foot and a half in height; the flowers being ſmall, and having little beauty, it is ſeldom preſerved but in botanic gardens. The ſeeds of this ſort muſt be ſown upon a moderate hot-bed in the ſpring, and the plants muſt be put into ſmall pots, and brought forward in another hot-bed. In july they will flower, when they may be expoſed in the open air, in a warm ſituation, where the ſeeds will ripen in ſeptember, and the plants will ſoon after decay.

8. The eighth ſort growing naturally in hot countries, is too tender to thrive in the open air in England. It is propagated by ſeeds, which muſt be ſown on a hot-bed in the ſpring; and when the plants are two inches high, they ſhould be each tranſplanted into a ſeparate ſmall pot filled with light earth, and plunged into a hot-bed of tanners bark, obſerving to ſhade them till they have taken freſh root; after which they muſt be treated in the ſame way as other plants from the ſame climate, always keeping them in a ſtove, which ſhould be of a moderate temperature of heat.

9. The ninth ſort may be raiſed on a moderate hot-bed in the ſpring, and afterward expoſed to the open air in ſummer; but in winter the plants muſt be ſheltered under a frame, otherwiſe the froſt will deſtroy them.

DESCRIPTION, *&c.*

This plant has creeping woody roots, which send out many black fibres, penetrating deep into boggy ground. Stems many, herbaceous, about two feet high, generally inclining to the ground. At each joint is one leaf, composed of five, six, or seven leaflets. The petals are not more than a third part of the size of the calyx.

[Stems cylindric, branched, a little hairy.—Lower leaves on long petioles, with broad stipules embracing the stem, bluntly lanceolate, having five or seven leaflets on short petioles, the odd one largest, the lower pair smallest, oval, deeply and acutely serrated, upper leaves on short petioles, with oval-lanceolate stipules, and five or three leaflets; others single, with lanceolate stipules: upper side of the leaves slightly hairy, under side and petioles downy. Peduncles numerous, each supporting a single flower, with a pair of lanceolate bractes. Segments of the calyx and petals acute and dark purple. Stamens, anthers, style, and receptacle black [a].—Petals marone-coloured. Stamens twenty to thirty, mulberry-coloured; anthers heart-shaped, the pollen yellow: styles marone-coloured; the stigma has sometimes a drop of transparent liquor. Receptacle conical, a little woolly [b].

Native of moist parts of Europe, in boggy ground.] A few plants are growing upon a bog at Hamstead, but the nearest place to London where it grows wild in plenty, is in the meadows near Guilford in Surry. [It is found also at Selborne in Hampshire: near Bromsgrove Lickey, in Worcestershire: Gamlingay in Cambridgeshire: in Norfolk: near Colchester, in Essex: Giggleswick Tarn, near Settle: in Scotland and Ireland. June. The roots dye wool of a dirty red colour, and have astringency enough, with other plants of the same order, to tan leather. The Irish rub their milking pails with it, to make the milk appear thicker and richer. Goats eat it. Cows and sheep are not fond of it. Horses and swine refuse it [a].]

β. There is a variety with thicker and more villose leaves, which grows plentifully in Ireland, and in the north of England; but after one year's growth in a garden it is not to be distinguished from the common sort.

PROPAGATION AND CULTURE.

This plant being a native of bogs, cannot well be preserved in a garden, except it be planted in a soil congenial to its natural one. The roots may be removed from the place of their growth in October, and will be be in no danger of succeeding if they are planted in boggy ground.

[COMBRETUM. (*The name of a plant in Pliny, described by him as very like the* Bacchar, *but taller, with the leaves drawn out so finely as to resemble threads.*)

Lin. gen. n. 475. *Reich.* 509. *Schreb.* 641. *Gærtn.* 36. *Juss.* 320. *Lœfl. it.* 308. 248.

Class. 8. 1. Octandria Monogynia.

Nat. order of *Calycanthemæ*. *Onagræ* Juss.

GENERIC CHARACTER.

Cal. *Perianth* one-leafed, superior, bell-shaped, four or five-toothed, deciduous.

Cor. *Petals* four or five, ovate, acute, inserted into the calyx, and scarce longer than it.

Stam. *Filaments* eight or ten, bristle-form, erect, very long: *Anthers* a little oblong.

Pist. *Germ* inferior, linear. *Style* bristle-form, length of the stamens. *Stigma* acute.

Per. none, except the cruft of the seed.

Seed single, four or five-angled; angles membranaceous; acuminate.

ESSENTIAL CHARACTER.

Cal. four or five-toothed, bell-shaped, superior. *Cor.* four or five-petalled, inserted into the calyx. *Stam.* very long. *Seed* one, four or five-angled, the angles membranaceous.

   Leaves alternate, flowers ten-stamened.

DESCRIPTION, *&c.*

This genus is very imperfectly known, and being a very fine one, deserves the attention of the cultivators of exotic plants. Probably some of the synonyms given above belong to different species, of which there are several known in Europe only from dried specimens.

1. This is a shrub with round scandent branches, the younger ones brachiate. Leaves ovate, acuminate, sometimes blunt, with or without a point, quite entire, smooth, petioled, three inches long. Spikes erect, three inches long, axillary and terminating. Flowers small, whitish, on very short pedicels [a].

Jacquin affirms, that the plant which Aublet has figured and described under the same name, is not his plant, although it have the same habit, for the flowers are totally different. He would unite

[a] Woodward Mf. [b] Withering.

[a] Withering & Lightfoot. [b] Jacquin.

Aublet's with Loefling's plant, and conſider them as a diſtinct ſpecies[a]. It ſeems indeed to agree better with our ſecond ſpecies, than with the firſt. The leaf and fruit in Aublet's figure agree well enough with Jacquin's of his *ſecundum*, but not with that of Gærtner, who refers to Aublet, and not to Jacquin.

This ſpecies is thus deſcribed by Swartz. Branches brachiate, the branches compreſſed a little at the tip, duſky ferruginous, pubeſcent. Leaves elliptic, large, entire, nerved. Flowers raceme-ſpiked. Common peduncle axillary on the terminating branches, erect, round, ferruginous-pubeſcent. Racemules oppoſite, ſpreading, many-flowered. Pedicels one-flowered. Calyx goblet-ſhaped, four-cornered, villoſe within, coloured. Petals four, with very ſhort claws, inſerted into the angles of the calyx, ovate, ſpreading, yelloviſh white. Filaments eight, twice as long as the calyx, ſpringing from the bottom of it: anthers ovate, minute. Germ roundiſh: ſtyle ſubulate-filiform. Capſule oblong, four-cornered, four-winged, one-celled. Seed four-cornered, the corners membranaceous and red, one-celled. It varies with narrower ovate-lanceolate leaves.

Native of the Weſt-Indies.

2. This is a ſmall tree, twelve feet high, ſupporting itſelf on other trees by its round and very long branches. Leaves ovate-oblong, acuminate, quite entire, ſmooth, veined, diſtich, petioled, four inches long, the upper ones on the flowering branchlets ſmaller. Spike pinnate, compoſed of ſeveral oppoſite ones in a double row uncertain in their number, and an odd one at the end, extended horizontally along with the extremity of the branch whence it ariſes: pedicels one-flowered, extremely ſhort, placed very cloſe to each other. Flowers very numerous, with ſcarcely any ſcent, yelloviſh green except the anthers, which are red, all turned upwards and erect, all together appearing like a creſt. The branches, when broken, and the leaves bruiſed, have a fetid and very unpleaſant ſmell.

Native of Carthagena in South America[b]; and alſo of Guiana.

3. This is a very ſmooth ſhrub, with round brachiate branches. Leaves petioled, oppoſite, three inches long, quite entire, ſomewhat coriaceous, a little attenuated at the tip, under the ſpikes an inch long, acute. Peduncles oppoſite, ſpreading very much, a ſhort ſpan in length, four-cornered. Flowers copious, ſcattered. A briſtle-ſhaped bractæ at the baſe of each pedicel. Calyx very ſmooth. Corolla purple. Seed roundiſh, retuſe, very ſmooth, of a ſhining golden colour. Native of the Eaſt-Indies[c].

4. This is a weak branching ſhrub, climbing to twenty feet in height, with prickles on the older branches. Leaves oval-oblong, quite entire, ſhining, petioled, two or three inches long, ending in a blunt channelled cartilaginous point. Spikes looſe, half a foot long, about ten on one common peduncle, at the ends of the branchlets, which are frequently continued weak and leafleſs ſix feet beyond the flowers. Pedicels very ſhort. Flowers ſmall and very numerous, coming out uſually before the leaves. Fruits browniſh. Native of Carthagena, flowering in may and june, and fruiting in july and auguſt[d].

COMETES. (*From κομητης, crinitus; the involucres being remarkably hiſpid.*)

Reich. gen. n. 167. *Schreb.* 211. *Juſſ.* 437.

Claſſ. 4. 1. Tetrandria Monogynia.

Nat. order of *Tricoccæ*.

GENERIC CHARACTER.

CAL. *Involucre* three-flowered, (flowers ſeſſile,) four-leaved; *leaflets* oblong, equal, ſpreading, ciliate-hiſpid.

Perianth four-leaved; *leaflets* oblong, equal, length of the involucre.

COR. none.

STAM. *Filaments* four, capillary, length of the perianth. *Anthers* roundiſh.

PIST. *Germ* roundiſh. *Style* filiform, length of the flower. *Stigma* three-cleft.

PER. *Capſule* tricoccous.

SEED ſolitary.

OBS. *It has an affinity with* Dalechampia.

ESSENTIAL CHARACTER.

Involucre four-leaved, three-flowered. *Cal.* four-leaved. *Capſ.* tricoccous.

SPECIES.

1. Cometes alterniflora.

Lin. ſyſt. 163. *Reich.* 342. *mant.* 39. *Burm. ind.* 39. *t.* 15. *f.* 5.

Clinopodium parvum ſinicum. *Pluk. amalth.* 61. *t.* 380. *f.* 4.

DESCRIPTION, *&c.*

Annual. Stem herbaceous. Leaves oppoſite, ſeſſile, obovate, acuminate, very entire, ſmooth. Peduncles axillary, alternate, ſolitary, one-flowered, patulous, the length of the leaves[e].

Stems a foot high, round. Peduncles in pairs, terminating and axillary, ſubalternate[f].

Native of Suratte.

COMFREY. See *Symphytum*.

COMMELINA. (*This genus was ſo named by Plumier, from the two Commelins, John and Caſpar, brothers, and famous Dutch botaniſts.*)

Lin. gen. n. 62. *Reich.* 68. *Schreb.* 86. *Gærtn.* 15. *Juſſ.* 45. *Brown.* 125. *Plum.* 38. *Zanonia. Plum.* 38.

Claſſ. 3. 1. Triandria Monogynia.

Nat. order of *Enſatæ*. *Junci* Juſſ.

GENERIC CHARACTER.

CAL. *Spathe* cordate, converging, compreſſed, very large, permanent.

COR. *Petals* ſix, of which the three exterior are ſmall, ovate, concave, reſembling a perianth; the three inferior ones alternate, very large, roundiſh, coloured.

Nectaries three, reſembling *ſtamens*, ſeated on their proper filaments, cruciform, horizontal.

STAM. *Filaments* three, ſubulate, reclined, agreeing in figure and circuit with the filaments of the nectary, but inferior to them. *Anthers* ovate.

PIST. *Germ* ſuperior, roundiſh; *Style* ſubulate, revolute, length of the ſtamens. *Stigma* ſimple.

PER. *Capſule* naked, nearly globular, three-furrowed, three-celled, three-valved. (ſuperior two or three-celled. *Gærtn.*)

SEEDS two, angulated.

OBS. *The number is different; hence if the four ſmall petals are equal, then out of the number of the other parts, exclude one third, and add unity to the nectaries, and you will have the number required.*

In Zanonia, *the three exterior ſmall petals continue in the form of a perianth; the three interior ones are equal.*

Some are for removing all the Zanonias *to the genus* Tradeſcantia.

ESSENTIAL CHARACTER.

Cor. ſix-petalled. *Neſt.* three, croſs-ſhaped, pedicelled.

SPECIES.

* *With two petals larger.*

Leaves ovate-lanceolate, waved, stem erect, angular, hairy, flowers panicled.]

DESCRIPTIONS, *&c.*

1. This is an annual plant, having several trailing stalks, that put out roots at the joints. At each joint is one leaf, which is smooth, of a deep green, marked with several longitudinal nerves, and embracing the stalk. Flowers axillary, two or three together, on short peduncles. Corolla composed of two large blue petals, and four small green ones.

[Stems, according to the observation of Dillenius, from a foot to two feet in length and more, branching. Leaves resembling those of *Sopewort*, feeling roughish if stroked from the base upwards, but having no hairs except at the edges of the sheaths.—Native of America, the West Indian islands, and Africa. Cultivated 1732, by Dr. Sherard, at Eltham [c].] It flowers in june and july, and the seeds ripen in autumn.

2. Root fibrous. Stalks many, trailing, three feet long, putting out roots at every joint, so that where it has room to spread, it will cover a large surface. The leaves are very like those of the first sort, but the flowers are larger, and of a deep yellow colour: the seed-vessels also are larger.

[It differs from the first in having larger kidney-form yellow petals, with a third ovate equal to them,

[a] Hort. kew.

but with longer filaments; the sheaths of the leaves are ciliated, the involucre not netted; the sheaths have another very small sheath within them [b].

Capsule ovate, two-valved, three-celled. Seeds in the upper cells, two, three or four, roundish, smooth, always barren; in the lower cell fertile, the whole covered with the valve growing to it, elliptic, flat above, and convex below [c]. Native of Africa.

Cultivated 1759, by Mr. Philip Miller [d].

It flowers in july, and the seeds ripen in autumn.

3. Root annual. (Loureiro says perennial.) Stems numerous, diffused, creeping at the base either by teats or fibres, then ascending to a span or foot in height, roundish, striated, hirsute, jointed, the internodes two inches long, branches from the very base, alternate, the lower ones longest. Leaves before they open rolled in, from an inch to an inch and half in length, nerved, pubescent, waved. Petioles ciliate with brown hairs, at first linear, then sheathing; sheaths marked with lines, spotted with purple. Spathe terminal, cowled, compressed, subtriangular, the apex turned down, the two sides united, marked with lines. Peduncle within the spathe double, one slender, longer, one-flowered, the other thicker, channelled, bearing from two to four flowers, on jointed round inflex pedicels. The two inner petals very large, blue, the four outer pale blue. Nectaries yellow [e]. Native of Bengal and Cochinchina.]

4. Root perennial. Stems a foot and half high, having a single leaf at each joint, shaped like those of the first sort, and embracing the stem. Flowers axillary at the upper part of the stalk, on short peduncles. Petals pale blue.

[Leaves subhirsute, but not hairy except at the sheath. The flowers are larger than in the first sort, plaited about the edge, and as it were crenated, finely striated. Of the three coloured petals the two upper only are conspicuous, the third is small and very narrow, whitish and pellucid; the three outer petals are slender, the upper one smaller than the other two, which are blueish. Capsules roundish, obtusely triangular, three-seeded [f]. Cultivated 1732, by James Sherard, M. D. [g].

5. Stems erect, simple, glossy, two feet high. Leaves scabrous on the upper surface, when rubbed from the base: sheaths nerved, subpubescent, ciliated about the edge with ferruginous hairs. Spathes terminating, subcordate. Flowers blue, with the petals cordate, and very entire; the lower one on a short pedicel [h]. The structure and fruit like that of the first species; but the capsule a little larger, and whitish; the seeds more wrinkled, and bay inclining to ash colour [i]. Native of Virginia. Perennial.]

6. This has a thick fleshy root composed of several tubers, somewhat like those of Ranunculus, several joining together at the top, where they form a head, and diminish gradually downwards: from this arise one or two inclining stalks, which put out side branches from their lower parts. Some of the leaves are on long petioles, others embrace the stalk; they have short hairs on their under surface, and towards the stalk, but are smooth above, of a deep green colour, and close every evening, or in cold weather. The flowers are axillary towards the upper part of the stalk, on slender peduncles. Corolla composed of three large, roundish, blue petals, and three smaller, which are green.

[Capsule ovate-acuminate, rather flatted, two-valved, three-celled; the upper valve divided longitudinally into two cells, but the lower one-celled, growing close to the seed: in each of the upper cells two tubercled ferruginous seeds; in the lower one, elliptic, smooth, compressed like a lens, bay-coloured. *Gærtn.* Cultivated 1732, in the Eltham garden, from seeds sent from Mexico, where it is said to grow on the mountains. It is used there externally for discussing tumours, and internally

[b] Linn. spec. [c] Gærtner. [d] Hort. kew.
[e] Murray. [f] Dillenius. [g] Hort. kew.
[h] Linn. spec. [i] Gærtner.

in hot plethoric habits [s].] Mr. Miller had it from La Vera Cruz in New Spain, by Dr. Houſtoun.

7. This has trailing ſtalks like the firſt, with narrow graſſy leaves, embracing the ſtalks with their baſe. The flowers are produced at the ends of the ſtalks upon thick peduncles, three flowers generally on each. The corolla has three equal large petals of a ſky blue, and three ſmaller, which are green.

[The ſheaths of the leaves are very wide and diſtant from the ſtalk, hirſute on the edge. There are two lanceolate oppoſite bractes [t]. Fruits berried, ſeſſile, in an ovate terminating raceme. Berries ſpurious, dark purple, formed of the corolla tranſmuted into a fleſhy, ſucculent, three-lobed calea, drawn over the capſule, and covering it totally. Capſule cylindric-ovate, cruſtaceous, dotted in rows, teſtaceous, three-celled, and opening into three parts at top. Seeds two, (ſometimes one) in each cell; one angular, a little wrinkled, aſh-coloured, having a little pap covering the embryo on the ſide; the other elliptic, plano-convex, a little wrinkled about the edge, bearing the embryo on the middle of the back [u].]

Native of the Weſt Indies; Mr. Miller had the ſeeds from the iſland of Barbuda. Cultivated 1759, by him.

It flowers from june to auguſt, but does not perfect ſeeds in England.

[8. Annual. Stems aſcending, numerous, ſomewhat ſcabrous. Leaves ſeſſile, acute, ſheathing. Peduncles terminating and axillary, elongated, ending in a ſtriated, lanceolate involucre, convoluted ſo as to be almoſt cylindric. Four filaments of the nectary, half the length of the ſtamens. Two filaments of the ſtamens, bearded, a little bent back, the length of the corolla: anthers yellow, ſpotted with black. Found by Koenig in the Eaſt-Indies [x].

9. Annual. Stem ſomewhat erect, decumbent at the baſe, ſomewhat ſcabrous, a ſpan in height. Leaves ſeſſile, acute, ſheathing. Peduncles terminating, two, a greater and a ſmaller. Flowers from four to ſix, pedicelled (without any involucre) nodding. Three filaments of the nectary, half the length of the ſtamens, naked. Two filaments of the ſtamens, bearded in the middle, declining where the corolla gapes. Found by Koenig in dry paſtures of the Eaſt-Indies [y].

10. Annual. Stem creeping, aſcending, ſomewhat ſcabrous. Leaves ſheathing, moſt minutely ſerrate; the upper leaf cordate-lanceolate; ſheaths ciliated on the edge. Panicle terminating, divaricate, with little ſheathing bractes. Three filaments of the nectary, a little ciliate on the ſides. Three filaments of the ſtamens, bearded, but naked above the middle: anthers blue. The ſtyle and ſtigmas are ſpirally convolved and evolved variouſly.—Obſerved by Koenig, in the Eaſt-Indies, in moiſt places near brooks [z].

Introduced 1781, by John Earl of Bute. It flowers in july and auguſt [a].

11. Stem erect, a ſpan high, creeping at the baſe with filiform roots. Leaves nerved, petioled, with ſheaths wider than the ſtem, ciliate at the edge, with diſtant, ſpreading briſtles. Involucres terminating, truncate, many-flowered, entirely coaleſcent by the ſide. Flowers peduncled, minute [b].

According to Loureiro, it is a foot and half high, and red. Leaves five-nerved, waved. The two large petals of the corolla bright blue; the four others he attributes to the calyx, and aſſirms that it certainly has no more than two large petals; though Linnæus, on the authority of Burmann, (Ind. 18. t. 7. f. 3.) puts it among the tripetalous ſpecies. Murray ſuppoſes it not to be different from C. benghalenſis. Probably Linnæus was of the ſame opinion. Native of the Eaſt-Indies, and Cochinchina, where it is a weed in their gardens.

12. Stem grooved, erect, hairy, panicled at top, a foot high. Leaves alternate, ſheathing, oblong, acute, ſmooth, the lower ones a finger's length, the upper ones an inch. Flowers on the panicled branches in racemes. Native of Japan [c].]

PROPAGATION AND CULTURE.

All the ſorts are propagated by ſeeds: the firſt will grow if ſown in the full ground; but if the ſeeds are ſown upon a warm border of light earth in autumn, the plants will riſe early in the ſpring; ſo from theſe good ſeeds may be expected, if the ſeaſon proves favourable; whereas thoſe which are ſown in the ſpring, often lie long in the ground, and rarely ripen their ſeed. Theſe plants have but little beauty, ſo that two or three of each ſort is as many as moſt people chooſe to have; therefore if the ſeeds are ſown in autumn where the plants are deſigned to remain, or the ſeeds permitted to ſcatter, the plants will require no farther care, but to keep them clear from weeds. The ſecond ſeldom ripens ſeeds in England, but the roots ſend out offſets, by which the plant is eaſily propagated. But it is too tender to live in the full ground in winter, unleſs it has a warm ſheltered ſituation; therefore ſhould be planted in pots, and ſheltered under a common frame in winter, and expoſed abroad in ſummer; the beſt time to tranſplant and part theſe roots is about the end of march.

The other ſorts are tender, their ſeeds therefore muſt be ſown on a moderate hot-bed in the ſpring, and when the plants are two inches high, they ſhould be tranſplanted to a freſh hot-bed to bring the plants forward: when they have taken freſh root, they ſhould have a large ſhare of freſh air admitted to them every day in warm weather, to prevent their growing weak; and in june theſe may be carefully taken up, and tranſplanted on a warm border of light earth, obſerving to ſhade them till they have taken freſh root: after which they will require no other care, but to keep them clean from weeds. With this management the plants will flower and produce good ſeeds.

The ſecond and ſixth ſorts may be continued, if they are planted in pots, and in autumn placed in the bark-ſtove; or if the roots of the ſixth ſort are taken out of the ground in autumn, and kept in a warm place in winter, they may be planted again in the ſpring, placing them on a hot-bed to forward their ſhooting, and theſe will produce ſtronger plants than thoſe which riſe from ſeeds.

[x] Linn. mant. [y] Ibid. [z] Ibid.
[a] Hort. kew. [b] Linn. mant. [c] Thunb. in Linn. tranſ.

DESCRIPTION, &c.

A tree, with alternate, obliquely ovate, acuminate, serrate leaves, hoary underneath. Flowers minute, panicled, hoary. The fruit very much resembles that of Sparrmannia, both in form and surface. It is thus described by Gærtner.—Capsule superior, subglobular, five-grained, five-valved. Rind coriaceous, echinated all over with soft villose bristles, opening into five parts at the top. Grains (cocculi) five, obovate, narrowed downwards, bony, gibbous on one side, angular on the other, semibilocular from the back, two-valved, the valves of the contiguous grains united and forming the proper partitions of the capsule. In each cell two seeds, ovate-oblong, a little thicker above, very slightly compressed, of a red-ferruginous colour, but blackish at the top; incompletely covered with an aril, which is membranaceous, very thin, whitish, lacerated, fixed to the navel of the seed, and covering the whole ventral, but not the dorsal part.—Native of Otaheite and the other Society isles *. Discovered april the 30th 1774.]

[3. Comocladia ilicifolia.

Swartz prodr. 17.

Ilex dodonæa. *Lin. spec.* 182. *Plum. gen.* 20. *ic.* 118. *f.* 1.

Leaflets angular-spiny.

DESCRIPTION, &c.

1. Seldom more than twenty feet in height (12 or 16. *Browne.* 10 to 30. *Swartz.*) Trunk erect (seldom growing to any considerable thickness. *Br.*), dividing into few branches, adorned at the end with pinnated smooth leaves like a frond, having at most eight leaflets on each side of a round rib two feet in length, with an odd one at the end; these are ovate-lanceolate, acuminate, slightly wrinkled by the transverse veins, the edges a little revolute, petioled, four inches long: from the axillas hang loose panicled racemes, a foot and half in length, divided into about twenty-four partial lateral alternate racemes; and these more or less compounded, the whole forming an ample panicle. Flowers very numerous, small, sessile, without scent, of a deep red colour: many of them have the calyx and corolla four-parted, with four stamens. Drupes red and shining: (black and succulent. *Swartz.*) The whole tree abounds in a watery sap, slightly glutinous, which grows black in the air, and dies the hands a deep black that can scarcely be washed out.

* Linn. suppl.

Native of Domingo and Jamaica, flowering in december, january and february *.

The fruit is eatable, but not inviting; and the wood is hard, of a fine grain, and reddish colour *.

Introduced 1778, by Mr. William Forsyth †.

2. It is very like the foregoing species. Leaflets from six to ten, oblong, acuminate, spiny-toothed, veined at the back, and subtomentose. Juice milky, glutinous, turning very black; not to be washed from the skin or cloth. If the tree be ever so slightly wounded, it has a strong smell of dung. The natives have a notion that it is dangerous to sleep under it. Native of Cuba *.

3. Leaves pinnate, with twenty-one leaflets, which are sessile, rigid, ovate, acuminate, angular in the middle on both sides, with a toothlet. Flowers racemed ‡.

Native of the West-Indies, as Antigua, &c.]

PROPAGATION AND CULTURE.

These plants are propagated by seeds, when they can be obtained from the places of their growth, which should be sown in pots, and plunged into a hot-bed: the plants, when fit to remove, should be each planted in a small pot, and plunged into a tan-bed, and in the autumn should be plunged into the bark-bed in the stove, and treated as other tender plants.

DESCRIPTION, &c.

This rises with slender shrubby stalks, near three feet high, they are hairy, and divide into several slender branches. Leaves from three to four inches long, and half an inch broad, alternately indented (or sinuated) almost to the midrib, and have a great

† Jacquin. ‡ Browne. ‡ Hort. kew.
‡ Jacquin. ‡ Linn. spec.

resem-

resemblance to those of Spleenwort; they are of a dark green, hairy on their under side, and sit close to the stalks. The aments of male flowers come out on the side of the branches between the leaves; they are oval, and stand erect. [The fruit is a bony nut, elliptic, turgidly lenticular, naked, smooth, shining, obscurely striated, bay-coloured, the size of a hasel nut. Inclosed is a single, ovate-globular, smooth, pale seed[a].

Native of North America; as in the county of Lancaster, and on the banks of Northampton river among the firs[b]. It flowers here from march to may. Cultivated in 1714, by the Dutchess of Beaufort[1].] Mr. Miller says, that many of the plants have been brought to England from Philadelphia.

PROPAGATION AND CULTURE.

Planted here on a loose moist soil it thrives very well, sometimes creeping at the roots, and sending up suckers plentifully, as in its native country. By these suckers it may be propagated. It will endure our cold very well.

[CONFERVA. *River-weed.*
Lin. gen. n. 1207. *Reich.* 1323. *Schreb.* 1672. *Dill. muse.* 11.
Class. 24. 3. Cryptogamia.—Algæ.

GENERIC CHARACTER.

Simple uniform hair-like thread-shaped fibres.
Obs. these fibres are either continuous or jointed.

ESSENTIAL CHARACTER.

Unequal tubercles, in very long capillary filaments.

Twenty-one species are recited in Linneus's system of vegetables, edit. Murr. These are all inhabitants of the water, some in fresh, but more in salt water.

Withering has forty-nine species, natives of England, in his third volume of the botanical arrangement of British plants, published in 1792. Most of them are figured by Dillenius; some by Micheli, Morison, Peiver, Ellis, in Flora Danica, &c.

A singular instance of irritability has been observed by Major Velley in the *Conferva corallina*, upon its being immersed when quite fresh, into fresh water. After it had been in the water a few minutes, several fibres were observed to move in an horizontal direction with a quick convulsive twitch, and then to stop suddenly: this they continued to do for some length of time; and the same effect may be produced several times, provided the plant be fresh. The experiment does not succeed in salt water.]

CONIUM. (*Κωνιον of Theophrastus and Dioscorides. From κωνια, dust, according to Linneus; but that cannot be right. Why is it not rather from κωνωπιον, circumago, on account of its inebriating poisonous quality.*)

DESCRIPTIONS, &c.

1. Root biennial, resembling that of a small Parsnep. Stem from four to six feet in height and upwards, hollow, round, shining, smooth, covered with a blueish powder, which easily wipes off, spotted and streaked with livid purple, towards the top branched and striated. Bottom leaves very large, even two feet in length, of a dark green colour, but paler underneath, shining, super-decompound, or several times pinnate: pinnules oblong, gashed and ferrate: petiole spotted, smooth, fistulous, succulent, round, being scarcely flatted at top: sheath grooved. Rays of the umbel ten to twelve; of the umbellule fifteen or sixteen. Universal involucre of three or five leaflets (sometimes seven), lanceolate, turned back and whitish at the edges: partial of three (or four) leaflets, on one side only, spreading outwards. Calyx entire. Corolla white; outer petals largest. Fruit ovate, gibbous, with compressed ribs, waved before it is ripe, but becoming almost straight. Seeds brownish, resembling those of Aniseed, with five notched elevated ridges, three on the back, and two on the side.

Hemlock is obviously distinguished by its large and spotted stalk; by the dark and shining green colour of its bottom leaves, and particularly by their disagreeable smell when bruised[a].

It is frequent by road and hedge sides, in cultivated ground, among rubbish, and on dunghills. Flowering in june and july.

According to Linneus, sheep eat the leaves. Horses, cows and goats refuse them. Ray informs us, that the thrush will feed upon the seeds, even when corn is to be had. Mr. Curtis remarks, that it appears to be eaten by very few or no insects. The dried fistulous stalks of this and several other umbellate plants, are called by the country people *Kexes* or *Keekſies*. Gerarde applies the name to this species.

[a] Curtis, Withering, Leers, Gærtner.

This plant which was ſtigmatiſed as one of the moſt noxious of vegetable poiſons, has of late years been conſidered as a highly uſeful and powerful article of the Materia Medica; and it has been proved by indiſputable experiments that though highly deleterious when imprudently uſed, yet in ſmall doſes it has been productive of conſiderable benefit in caſes which have reſiſted the uſual methods. It has been particularly celebrated in cancerous caſes.

The firſt phyſician who endeavoured to bring Hemlock into repute as a medicine was Baron Stoerck of Vienna, who announced its extraordinary effects in the year 1760. To enumerate all the diſeaſes in which he ſets forth its powerful effects, would be to give a catalogue of moſt of the chronic diſorders that affect mankind. To eſtimate with preciſion however the virtues of Hemlock ſeems no eaſy taſk: had Dr. Stoerck's publication contained fewer and leſs extraordinary inſtances of ſucceſs, its virtues might have been held in higher eſteem than they at preſent are; while thoſe authors who have condemned it as entirely uſeleſs and highly dangerous ſeem to have done it equal injuſtice: for though in our own country we cannot adduce inſtances, like thoſe mentioned by Dr. Stoerck, of its curing inveterate cancers, ulcers, *&c.* we have ſtill the teſtimonies of eminent practitioners in favour of its good effects in ſome caſes which had reſiſted the uſual applications, and that even ſome caſes, which if not really cancerous, were at leaſt ſuſpected to be of a cancerous tendency, were greatly benefited by it. In chronic rheumatiſms, alſo, and in ſome glandular ſwellings, as well as in various periodical pains, the Hemlock is frequently employed. Externally the leaves have been applied with advantage to ulcers, indurated tumours, *&c. &c.*

Much has been ſaid reſpecting the variable nature of the plant; the time of collecting and preparing it, *&c.* according to which its efficacy muſt undoubtedly be greater or leſs. The principal point however ſhould ſeem to be the due regulation of the doſe, which requires the conduct of a ſkilful practitioner, beginning with a few grains perhaps of the extract or powder, and gradually increaſing it till a ſlight tendency to vertigo or other ſymptoms manifeſt the full ſufficiency of the quantity. The extract from the ſeeds is ſaid to produce giddineſs ſooner than that from the leaves.

According to Dr. Withering, the powder of the dried leaves ſeems to act with more certainty than the extract. He recommends the following method.

Let the leaves be gathered about the end of june when the plant is in flower. Pick off the little leaves and throw away the ſtalks. Dry the abovementioned little leaves in a hot ſunſhine, or in a tin dripping-pan or other convenient veſſel before the fire. Preſerve them in bags of ſtrong brown paper, or powder them and keep them in glaſs phials, and put them in a drawer or any place where the light does not come; for it is obſerved that the light has the power not only of taking away their fine green colour, but alſo their virtue. From fifteen to twenty grains of this powder may be taken twice or thrice a day. It is found to be particularly ſerviceable in chronic rheumatiſms.

Dr. Stoerck's method of making the Extract of Hemlock (extractum cicutæ of the ſhops) is to take the freſh juice of the leaves, and inſpiſſate it gently over the fire, till it has acquired the conſiſtence of a thick extract: this is to be mixed with ſo much of the powdered leaves as will be ſufficient for making the maſs into pills.]

8. This variety, which Mr. Miller would have to be a diſtinct ſpecies, differs according to him, in having taller ſtalks not ſo much ſpotted as our common ſort. The leaves are alſo much narrower, and of a paler green. It is a native of Germany, whence the ſeeds were ſent to Mr. Miller, who cultivated the plant in the botanic garden at Cheſſea above twenty years without its varying.

[2. Stem ſhrubby, ſhort, ſtiff; branches longer, ſpreading very much, remote. Leaves bipinnate, doubled, obtuſe, crenulate, hard, the colour of Rue. Umbel rigid, ſhort, crowded. Involucre five-leaved, ſhorter than the umbellules, with one or two foliaceous, divided leaflets. Partial involucres ſeven-leaved, with few crenate leaflets. All the flowers fertile, white; petals lanceolate, involute, equal. Styles white, filiform.—Native of the Cape of Good Hope, on the coaſt [b].

Introduced 1787, by Mr. Fr. Maſſon. It flowers in june [c].

3. Leaflets flattiſh, not channelled, ſmelling like Smallage or Celeri. Peduncles oppoſite to the leaves, not furrowed as in the foregoing. Many of the flowers barren. The central fruit ſeſſile [d]. Seeds longer than in the common ſort. Annual.—Native of the Cape of Good Hope.

Cultivated 1759, by Mr. Miller [e], who received the ſeeds from the famous Boerhaave.

4. David van Royen received this from Egypt. Monſ. Lamarck regards it rather as a ſpecies of Caucalis.

5. Stem herbaceous, upright, a foot high, ſcarcely branched, ſlender, round, ſmooth, ſlightly ſtreaked. Leaves very narrow, a little wider at the baſe and ſomewhat ſheathing, very ſmooth; the lower ones four inches long or a little more; ſtem-leaves remote. Peduncles lateral and terminating, few, remote. Involucre five-leaved; leaflets ſubulate, ſomewhat rigid, ſhorter than the umbel. Involucels the length of the umbellule. Umbel ſmall, five-rayed. About eight or ten flowers in the umbellule. Seeds oblong, ſtriated, ſmall, ſmooth. Styles permanent, divaricating.—Native of the Cape of Good Hope [f].

PROPAGATION AND CULTURE.

1. Common Hemlock growing wild in moſt parts of England, is ſeldom allowed a place in gardens; it may however eaſily be propagated from ſeeds; and if theſe be permitted to ſcatter, plants will come up plentifully, and only require to be thinned for medical uſe.]

2, 3. The ſeeds of the Cape ſorts ſhould be ſown in pots in autumn ſoon after they are ripe, and placed under a common frame in winter, where they may be expoſed to the open air at all times when the weather is mild, and only covered in bad weather. The plants will come up early in the ſpring, and muſt then be expoſed to the open air conſtantly when the weather will permit, otherwiſe they will draw up very weak. As they do not bear tranſplanting well, they ſhould be thinned to four or five in a pot, and then require only to be kept clean, and to be watered in very dry weather.

[The ſecond ſort may alſo be increaſed by cuttings.

Vahl. symb. 3. 86. *Lamarck encycl.* 2. 95. *Cavan. diss.* 7. *t.* 221.
Leaves ternate lanceolate-elliptic, veins protuberant underneath.

3. Connarus Santaloides.
Vahl. symb. 3. 87.
Santaloides. *Linn. zeyl. n.* 408.
Leaves pinnate, leaflets ovate-acuminate, peduncles axillary aggregate, flowers racemed.

4. Connarus mimusoides.
* *Vahl. symb.* 3. 87.
Leaves pinnate, with about ten pairs of oval-oblong emarginate leaflets, racemes axillary.]

DESCRIPTION, &c.

1. It rises with a woody stalk eight or ten feet high, hard, rigid, covered with a blackish bark, dividing at top into two or three branches. Leaves alternate, trifoliate, on long petioles: leaflets ovate, smooth, entire, thick, each on short petiolules, and remaining green the whole year. Flowers in large upright racemes at the ends of the branches: they are small, hairy, of a greenish yellow colour, and rarely produce seeds in Europe.

Native of the island of Ceylon. [Cultivated by Mr. Miller in 1768.

2. Branches round smooth. Leaves petioled, alternate: leaflets petioled, quite entire, ending in a long point, very smooth, the upper surface even, the nerves and veins, which are transverse abundant and almost simple, being immersed, but underneath they are protuberant. Partial petioles wrinkled, thickened next the leaflet, the middle one longer than the other two. Flowers in a terminating spreading panicle.

Native of the mountains of Sierra Leone.

3. Branches round, smooth, with a purplish brown bark. Leaves petioled, scattered, remote, unequally pinnate, with from two to four pairs of leaflets, which are almost opposite, sometimes an inch and half long, equal, quite entire, ending in a blunt point, very smooth, netted-veined on both sides, with the veins a little protuberant, the upper surface shining. Partial petioles very short, channelled above. Peduncles axillary (four to six), half the length of the leaf, smooth; partial ones scattered, having towards the top three or four pedicelled flowers. Calyx ovate, the five segments lanceolate, acute; when in fruit bell-shaped. Petals twice as long as the calyx. Filaments unequal, the length of the corolla, scarcely united at the base. Capsule smooth.

Native of the East Indies.

4. Branches round, villose towards the top. Leaves towards the ends of the branches, petioled, alternate, approximating, unequally pinnate, with from nine to eleven pairs of leaflets, which are on very short petioles, opposite or alternate, the inner ones smaller, smooth, very finely veined on the upper surface, blunt, deeply emarginate, paler underneath. Petioles very slightly villose. Peduncles axillary, usually three together, the length of the leaves, slightly hoary. Pedicels scattered, filiform, the lowest commonly two-flowered at the end. The flowers are small, and there is a minute bractle at the base of each pedicel. The parts of the flower as in the foregoing species.

Native of the islands of Nicobar *.]

PROPAGATION AND CULTURE.

1. This plant is usually propagated in the gardens by laying down the young branches, which, if tongued, (in the manner practised for Carnations) and duly watered, will put out roots in twelve months, when they may be cut off from the old plants, and each planted in a separate small pot, filled with fresh light earth, plunging them into a moderate hot-bed, to forward their taking new root, observing to shade them from the sun every day, and to water them as they may require it; after this the plants should be treated in the same way as other exotic plants which are not too tender, placing them in a dry stove in winter, and for about three months in the summer they may be removed into the open air, in a warm sheltered situation.

The cuttings of this plant will sometimes take root, if they are planted in pots, plunged into a moderate hot-bed of tanners bark, and closely covered with hand-glasses, or small bell-glasses; but unless they are carefully managed they seldom succeed.

If fresh seeds can be procured from abroad, they should be sown in small pots, plunged into a moderate hot-bed, and when the plants are fit to remove they should be separated, planting each into a separate pot, and plunged into a moderate hot-bed, treating them in the same manner as the layers.

Leaves lanceolate-ovate blunt; fruits fegregate.

DESCRIPTION, &c.

1. This is an upright, branching tree, frequently exceeding thirty feet in height. The younger branches are angular. Leaves acute, quite entire, greasy to the touch, alternate, on very short broad petioles, numerous. Racemes simple, lax, often leafy, terminating and axillary: the peduncles bear-

* Vahl.

ing a receptacle, which collects the germs into a roundiſh head. The flowers are ſmall, and of a yelloviſh colour: in the iſland of Martinico they have ten ſtamens, twice as long as the calyx; in other places they have five ſtamens only, not longer than the calyx; but the ſtyle is twice as long. Perhaps this may be a different ſpecies. The head of flowers is globular, but of fruits rather ovate[s].—Native of the Weſt Indies, and all the coaſts of America between the tropics in great plenty, near the ſea and in ſalt water. For burning it is eſteemed the beſt wood in thoſe latitudes, but being ſmall it is of little other uſe. The Engliſh call it Button-tree and Button-wood; the Spaniards Mangle Saragoza.

2. This is a very branching ſhrub, almoſt the whole of it procumbent. Leaves obovate, but ſometimes approaching a little to a roundiſh form, blunt with a point, ſhining, quite entire, alternate, petioled, an inch or an inch and half in length, with an oblong gland on the edge next the baſe on both ſides. Flowers with five (ſometimes ſix) ſtamens, in other reſpects like the foregoing, only ſmaller in all their parts.

Native of Cuba, on rocks near the coaſt.

This may perhaps be only a variety of the foregoing. The farther it is removed from the coaſt, the more the leaves approach in their form to thoſe of *C. ereƈta*, and the more upright ſome of the branches become[t].]

Mr. Miller ſays, it has ſhort crooked branches, covered with a grayiſh bark, and having thick leaves on their upper parts, a little larger than thoſe of the dwarf Box, on ſhort petioles and placed on every ſide without order. The flowers are in ſmall round heads, coming out ſingly from the ſide of the branches, and in looſe ſpikes at the end: they are ſmall and of an herbaceous colour; the ſcales are rough, and the cones are of a looſer texture than thoſe of the former ſort. It was diſcovered by Dr. Houſtoun growing plentifully in the marſhy grounds near the ſea, at the Havanna, whence he ſent the ſeeds to England in 1730.

[3. This is a lofty and branching tree, ſometimes dividing into three or four trunks cloſe to the ground. The younger branches are ſhining, red and oppoſite. Leaves quite entire, ſhining, thickiſh, greaſy to the touch, deep green, oppoſite, three inches long, on a red petiole with two glands at the top of it. Racemes ſimple, terminating, commonly by threes: or, as is frequently the caſe in dwarf ſhrubs, compoſed of three oppoſite ones on each ſide, which are either ſimple or trifid, and of one ſimple terminating one in the middle; but in theſe ſhrubs the flowers are much ſmaller, and moſt of them, having little or no germ, are abortive. The flowers are ſmall and ſeſſile, and have a ſlight not unpleaſant ſmell. The petals are whitiſh. Stamens ten, five alternately ſhorter, probably ſometimes overlooked; (hence Browne attributes only five ſtamens to the flower). The ſeed, incloſed within a coriaceous pericarp, is compoſed of two greeniſh ovate *lamellæ*, wrapped up into a round body, and involved in a very thin membrane. The lamellæ in the baſe of the pericarp become a round obtuſe ſhining body, forming the axis of the ſeed, deſtined to put forth the roots: for when the capſule falls to the ground, it penetrates the crowned apex, and when the fibres take poſſeſſion of the ſoil, it conſtitutes the rudiment of the future trunk: then the lamellæ increaſing in bulk burſt the capſule, and become the radical leaves. Sometimes there are two ſeeds incloſed in the ſame pericarp. From the above deſcription it appears that this tree, although it agrees in many reſpects, yet differs very much from the two former ſpecies.

Native of the Caribbee iſlands and the neighbouring continent, on ſandy and muddy ſhores.

The Spaniards call it *Mangle bobo*, or fooliſh Mangle; the Engliſh *White Mangrove*.

The natives employ the bark for tanning leather: theſe trees ſeem to be otherwiſe of little uſe[s].]

PROPAGATION AND CULTURE.

1, 2. Both theſe ſorts are preſerved in ſome curious gardens for the ſake of variety, but they are plants of no great beauty: they are propagated from ſeeds, which muſt be obtained from the places of their natural growth, for they never produce any good ſeeds in Europe: theſe ſeeds, if they are freſh, will come up very ſoon, if they are ſown upon a good hot-bed; and if the plants are potted, and preſerved in the bark-ſtove, they will make great progreſs; but they are too tender to live in this country, unleſs they are conſtantly kept in the ſtove, and treated in the ſame manner with other exotic plants; obſerving, as they are natives of ſwamps, to ſupply them often with water; but in winter they muſt have it very ſparingly. The plants are Evergreen, caſting off their old leaves when the new come out.

SPECIES.

1. Conopea aquatica.
Conobea aquatica. *Aubl. guian.* 2. 639. *t.* 257.

DESCRIPTION, *&c.*

This is a creeping plant, with parcels of ſmall fibrous roots at the joints. It ſpreads over the neighbouring graſs, and on the ſurface of the water, by the ſide of which it naturally grows. The ſtems and branches are ſquare, and each angle is bordered its whole length by a very thin ſharp leaf or wing. Leaves oppoſite, at each joint, claſping, diſtant three quarters of an inch from each other, kidney-form, plaited at the nerves, and waving on the edge. Flowers either ſolitary or in pairs oppoſite from the axil of the leaves, on a ſlender peduncle an inch in length. The calyx has two long narrow pointed leaflets at the baſe. Corolla blue. Capſule marked with four grooves, partly wrapped up in the calyx, opening into four parts to the baſe. Seeds faſtened to a receptacle which riſes up in the centre at the bottom of the capſule.

Native of Guiana, flowering in june[t].

DESCRIPTIONS, *&c.*

1. [Root perennial, with numerous round fibres tranſverſely wrinkled, creeping horizontally juſt below the ſurface to a conſiderable diſtance. The whole plant is ſmooth. Four or five alternate, oblong, blunt, ſlightly nerved, purpliſh ſcales, ſurround and bind together the baſe of the leaves and ſtalk.

ſtalk. Leaves two, petioled, elliptic or lanceolate, pointed at each end, from four to five inches long, and near an inch and half broad in the middle, quite entire, upright, ſmooth, nerved, one uſually larger, of a bright green colour; petioles claſping, round, the outer dotted with red, and tubular, to receive the inner, which is ſolid. Scape lateral, the length of the leaves, upright, ſmooth, ſemicylindrical. Bracte lanceolate, membranous, white, under each pedunclc, and about half its length. Flowers ſix to eight, in a raceme, nodding, white, fragrant. Peduncles bending, one-flowered, round, filiform. Corolla contracted at the mouth. At the baſe of each filament a purple ſpot[a]. Berry red ſuperior, ſphæroid, ſmooth, one or two of the three cells often obliterated; two ſeeds in each cell, but one uſually abortive, almoſt globular, obſcurely angular.

Authors differ extremely reſpecting the number of ſeeds in this fruit.

Native of Europe, from Lapland to Italy, in woods. In Britain, near London on Hampſtead heath, but now ſparingly, ſince the trees have been deſtroyed; in Lord Mansfield's wood near the Spaniard; between Shooter's-hill and Woolwich; Norwood abundantly, where I have frequently ſeen large patches with very few flowers and no berries; Buſhy-heath, Caſhioberry in Hertfordſhire; near Chiſelhurſt in Kent; near Lee in Eſſex; Woburn in Bedfordſhire, whence the markets in London (as Mr. Miller ſays) are generally ſupplied with the flowers. Whichwood foreſt in Oxfordſhire, and in Beechwood, near Stokenchurch. White-wood near Gamlingay in Cambridgeſhire; Norfolk; Buddon and Okely woods in Leiceſterſhire; King's Cliff in Northamptonſhire; Kendal in Weſtmoreland; County of Durham; Ingleborough in Yorkſhire. Scotland.

It flowers in may, whence it is named May-Lily. Gerarde calls it Convall Lillie; and ſays that in ſome places it is called Liriconfancie.

The Lily of the Valley claims our notice both as an ornamental and a medicinal plant. As an ornamental one, few are held in greater eſtimation; indeed few flowers can boaſt ſuch delicacy with ſo much fragrance[b]. When dried they have a narcotic ſcent; and if reduced to powder excite ſneezing. An extract prepared from the flowers, or from the roots, partakes of the bitterneſs, as well as of the purgative properties of *Aloes*. The doſe is from twenty to thirty grains[c]. A beautiful and durable green colour may be prepared from the leaves, with lime[d].

There are ſeveral varieties of the Lily of the Valley: as one with narrower leaves mentioned to be found in Weſtmoreland by Mr. Lawſon; but upon being removed into Dr. Richardſon's garden, it became in all reſpects like the common ſort[e]. Another with broader leaves, from the Alps, which Mr. Miller ſays retained its difference in the garden, in the ſame ſoil and ſituation with the common ſort, and therefore he has no doubt of its being a diſtinct ſpecies.—A third, with a double variegated flower, ſuppoſed to be only a variety of this, though the flowers are much larger, and beautifully variegated with purple. It came from the royal garden at Paris, and flowered ſeveral years in the Cheſſea garden; but the roots do not increaſe ſo much as the common ſort.—A fourth, with reddiſh or red flowers; this Mr. Miller affirms continued the ſame above forty years: the flowers are ſmaller, the ſtalks redder, and the leaves of a darker green than in the common ſort. [Both this, and the white, vary with double flowers.

2. Root-leaves ten or more, linear, drawn to a point at bottom, three-cornered, flat on one ſide, entire, ſtriated, bent back, two feet long and upwards. Scape finely ſtriated, ſmooth, a ſhort ſpan in height, flowering at the end, four-cornered. Flowers ſtanding on one ſide; peduncles aggregate (two to ſix) uſually one-flowered (one to four). Bracte lanceolate, white, ſhorter than the pedunclc. Corolla white; diviſions lanceolate, patulous, a line in length. Filaments hardly any: anthers linear, acute, brown. Style the length of the corolla. Berry ovate, obtuſe, ſmooth, blue, the ſize of a pea, one-celled, adorned with the permanent calyx. Seed one, white, filling the whole berry.—There are two varieties, a larger and a ſmaller. They are found near Nagaſaki in Japan. Both there and in China, the tubers of the roots preſerved with ſugar, are uſed in ſome diſorders[f].

Introduced 1784, by Mr. John Graeſer[g].

3. Root fibrous. Root-leaves linear, drawn to a point at bottom, bluntiſh, many-ſtriated, ſmooth, longer than the ſcape, which is angular, ſimple, erect, ſmooth, from four inches to a foot in height. Raceme a finger's length, with the flowers ſcatteringly aggregate. Peduncles round, ſpreading, ſmooth, one-flowered, a line in length. Corolla ſix-petalled, almoſt globular, violet; petals ovate. Filaments inſerted into the germ, very ſhort, erect: anthers ovate, twin. Germ with ſix ſtreaks: ſtyle ſhorter than the ſtamens. Fruit obſcure, but ſeems to be a globular berry: in another ſpecimen it appeared to be a three-celled capſule, with two ſeeds in each cell.—Japan, flowering in ſeptember[h].

4. Root perennial, toothed. Stem ſimple, angular, ſtriated, erect, eighteen inches high. Leaves narrower than the reſt, lanceolate, entire, ſmooth, three or four in a whorl, three or four inches long, and from half an inch to an inch in breadth, bright green, glaucous beneath. Peduncles axillary, ſolitary, branched, pendulous, from two to ſix-flowered. Corollas oblong, greeniſh white, ſtriated at the ends, and divided into ſix bluntiſh ſegments, bearded within at the tip; three or four lines in length. Berries violet or deep red. It flowers in june[i], and was cultivated in 1656, by John Tradeſcant, junior[k]. Native of the North of Europe, Germany, Switzerland, Carniola. Ray obſerved it near Spa, and on mount Saleve near Geneva.

It was found by Arthur Bruce, Eſq. july the firſt, 1792, in the Den Rechip, four miles N. E. of Dunkeld in Perthſhire[l].

β. The ſtalk is ſometimes branched. *In this ſtate* it is deſcribed by Cluſius and others as a diſtinct ſpecies.]

5. Root twiſted and full of knots, on a tranſverſe ſection of it characters appear that give it the reſemblance of a ſeal, whence its name of Solomon's Seal.

[Stem from a ſpan to near a foot in height, of a harder texture than the *multiflora*: ſimple, inclined, angular, twiſted, ſometimes three-edged, four inches long and one broad, oval-lanceolate, half embracing the ſtem, glaucous underneath, frequently bending down on one ſide. Flowers ſweet-ſcented generally ſolitary, but ſometimes two, on long axillary peduncles, much larger than in the *multiflora*; (eight lines long, and more than two lines broad) white, with a green line running down each ſegment: ſegments rather inflexed. Berries black.—Diſtinguiſhed from the *multiflora*, by the ſtem being angular, firm, lower, from a foot to near eighteen inches; leaves firmer, ſhorter, ſcarcely ſtem-claſping; the flowers uſually ſolitary, larger though on a ſmaller plant, hardly reflexed, the three outer ſegments larger. Fruit round, black, containing ſix ſeeds, at leaſt that ſeems to be the natural number[m].

Native of the north of Europe. Holland, Germany, Hungary, Switzerland, Carniola, Piedmont. In England, in fiſſures of rocks near Wherſ, Settle, and Skipton; Syke's wood near Ingleton, Yorkſhire. Alſo in Virginia.

This varies with a double flower.

β. The variety with leaves like white Hellebore, and a purpliſh ſtalk, was found in woods on the north ſide of Mendip hills by Mr. Bobart.

[a] Curtis, Lyons, Woodw. mſs. [b] Curtis. [c] Witherieg. [d] Haller. [e] Ray's ſyn. [f] Thunberg. [g] Hort. kew. [h] Thunberg. [i] Krocker, Pollich, Haller. [k] Hort. kew. [l] Engl. Botany. [m] Haller, Linn. ſuec. Pollich, Villars, With. Woodw. mſs.

6. This agrees with C. Polygonatum and multiflora in root and habit, but the root is rather more ſlender, has at firſt a ſweet and then an acrid taſte, and is glutinous. Stem from half a foot to two feet in height, round at bottom and thence angular the whole length, the angles being more remarkable below the middle of the back of the leaf; it has a ſhort pile of hairs towards the top. Leaves ovate narrowing into a point, ſeſſile, many-nerved, with hairs on the nerves underneath, viſible only with a magnifier; quite entire, ſhining on both, eſpecially the upper ſurface, paler green on the lower, but not at all hoary. Peduncles ſomewhat hirſute, ſuſtaining one, two, and three flowers on the ſame plant, and on large plants four at bottom, each on its proper pedicel, pendulous and ſweet-ſcented. Corolla three times as large as in C. multiflora, tubular, white with obſcure lines more of a yelloviſh green, the border greeniſh, patulous, obtuſe, not funnel-ſhaped. Stamens inſerted below the middle of the tube. Style riſing above the origin of the border. Berry globular, very dark blue, three-celled, with three or four, ſometimes five ſeeds in each cell. Native of Auſtria [a].

7. Stem round, from eighteen inches to two or three feet high, erect, unbranched. Leaves uſually bent upwards and to one ſide, underneath glaucous, five inches long and two broad; the lower ones oval, the upper oval-lanceolate, half embracing the ſtem. Flowers ſeveral together (from two or three to ſeven or eight), axillary, on branched compreſſed peduncles: they are ſeven lines long and three in diameter, ſlightly five-cornered; the ſegments ovate, obtuſe, ſomewhat reflex. Filaments hirſute. Berries round, of a blackiſh blue colour, varying to purple and red, and containing three or four ſeeds.

It is a larger plant than the fifth ſort. The ſtem is leſs furrowed; the leaves are larger; the flowers ſeveral together, ſmaller with the ſegments more pointed, the colour white tipped with green, the tube longer and narrower, on ſhorter and more ſlender peduncles [b].

Native of the north of Europe, Germany, Switzerland, Carniola. England, at Newberry and other places in Berkſhire, Bramdean in Hampſhire, Roehill in Kent, High Wycomb in Bucks, Gorleſtone in Suffolk.

The roots are recommended externally as vulneraries, reſtringents, and diſcutients; internally as incraſſants and mild corroborants. They have little or no ſmell; to the taſte they diſcover a conſiderable ſweetneſs, which is followed by a very ſlight impreſſion of bitterithneſs and acrimony. Their virtues do not appear to be very great [c].

According to Haller the berries excite vomiting, and even the leaves a naufea. The young ſhoots are eaten by the Turks as we do Aſparagus; and the roots both of this and of the fifth ſort have been made into bread in times of ſcarcity.

This varies with a double flower.

β. The dwarf Engliſh Solomon's Seal occurs in the woods of Wiltſhire. Being found there by Mr. Philip More, gardener of Gray's Inn [d].]

8. Stems two feet high, unbranched, with many oblong leaves embracing them at the baſe, reſembling the leaves of Plantain. The flowers are ſmall and white, and are produced in ſingle ſpikes at the top, and are ſucceeded by ſmall red berries, about the ſame ſize as in the firſt ſort, and contain two hard ſhining ſeeds. It flowers the beginning of june, and the berries ripen in autumn. Native of Virginia and Canada.

[Cultivated 1656, by Mr. John Tradeſcant, junior [e].]

9. Stem upright, about two feet high. Leaves long and narrow in whorls, generally five at each joint; they are four inches long, and half an inch broad, ſmooth, and of a light green. The flowers come out from the ſame joints on ſhort peduncles, each ſupporting five or ſix flowers; ſmall and with ſhort tubes, of a dirty white tipped with green, and ſlightly cut into ſix parts at top. Native of Canada.

[Cultivated 1640, by Mr. John Parkinſon [f].

10. Root creeping, jointed. Stem-leaves two, three, or four, often ovate-oblong, but not ſeldom lanceolate. Flowers five to eight or nine thinly diſpoſed on a ſcape, on peduncles about a third of an inch in length, cloven almoſt to the bottom. Berries round, red, containing two or three large, yelloviſh, compreſſed, roundiſh ſeeds, with a ſmall point at the end.—Native of Siberia, in woods [g].

11. This plant ſeldom grows more than four or five inches high; riſing with a ſingle ſtalk from the root, with one or two heart-ſhaped leaves, which cloſely embrace it. The top of the ſtalk is terminated by a looſe raceme of white flowers, which have ſhort tubes, and ſpread open at the top, where they are divided into four obtuſe ſegments. The fruit is a ſoft berry, incloſing a ſingle hard ſeed [h].

Stem erect, angular, with purple dots. Petioles furrowed underneath, ſmooth, three lines in length. Leaves acuminate, two inches long and one broad. Raceme ovate, obtuſe, above half an inch long, containing as far as ſixteen flowers. Two peduncles, each ſuſtaining one flower, come out together. Bractes very ſmall, toothletted, whitiſh. Berries round, at firſt whitiſh, with red dots, afterwards becoming red: incloſing two or three ſeeds, which are nearly round, obtuſe and ſmooth [i]. One or two of them are frequently abortive.

In the ſpring it produces a ſingle leaf on a long erect petiole; after that a ſecond, and ſometimes a third [k].

As this pretty plant excludes a third part in the diviſions of the corolla and number of the ſtamens, ſo it does alſo in the piſtil; for the ſtigma is ſlightly biſid, and the berry is two-celled [l].

Native of the North of Europe, Holland, Germany, Switzerland, Carniola. Mr. Miller gathered it near Haerlem and the Hague, where Mr. Ray had gathered it before on the 28th of may in flower. Linnæus obſerves, that this plant ſo common in Sweden, does not occur in England.

It was cultivated 1739, by Mr. Miller [m].]

PROPAGATION AND CULTURE.

1. The Lily of the Valley requires a looſe ſandy ſoil, and a ſhady ſituation. It is propagated by parting the roots in autumn, placing the ſets a foot aſunder. In a rich ſoil they ſpread and multiply greatly, but are not ſo productive of flowers. The only culture they require, is to keep them clean from weeds, and to tranſplant and ſeparate the roots every third or fourth year: if this be not done the flowers will be ſmall and few in number.

[The Lily of the Valley forces very well, and thus theſe elegant flowers may be enjoyed above two months [n].]

4, &c. All the ſorts of Solomon's Seal are very hardy plants. They prefer a light ſoil and a ſhady ſituation, and are therefore very proper for plantations, where if they are not crowded by ſhrubs, they will thrive and multiply exceedingly, making an agreeable variety during the ſummer ſeaſon, the appearance of theſe plants being very ſingular.

They multiply very faſt by their creeping roots, eſpecially in a proper ſoil and ſituation. The beſt time to tranſplant and part the roots is in autumn, ſoon after the ſtalks decay; but it may be ſafely done at any time till they begin to ſhoot in the ſpring. They ſhould have room to ſpread, and muſt not be removed oftener than every third or fourth year. Dig the ground about them every ſpring, and keep them clean from weeds.

11. [As this plant propagates very faſt by its creeping roots, they will ſoon ſpread over a large piece of ground, unleſs they are confined in pots. Where they have room to ſpread the plants ſeldom produce berries: this is the caſe with many other creeping-rooted plants [o].]

CONVOLVULUS. (*A convolvendo: because the ſtem of ſome ſpecies rolls round, or twines about other bodies.*)

Lin. gen. n. 215. *Reich.* 231. *Schreb.* 287. *Gærtn. t.* 134. *Tourn.* 57. *Juſſ.* 133.

Claſſ. 5. 1. Pentandria Monogynia.

Natural order of *Campanaceæ*, or bell-form flowers. *Convolvuli* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-parted, converging, ovate, obtuſe, very ſmall, permanent.

COR. one-petalled, bell-ſhaped, ſpreading, large, plaited, obſcurely five-lobed.

STAM. *Filaments* five, ſubulate, ſhorter by half than the corolla. *Anthers* ovate, compreſſed.

PIST. *Germ* ſuperior, roundiſh. *Style* filiform, length of the ſtamens. *Stigmas* two, oblong, broadiſh. (Stigma bifid, *G.*)

PER. *Capſule* enwrapped by the calyx, roundiſh, two-celled, one, two, or three-valved (commonly three-celled, ſeldom two or four-celled, *J.* partition alternate with the valves.)

SEEDS in pairs, roundiſh, (one or two ſeeds in each cell, ſometimes abortive, *J.* few with a twiſted embryo, *G.*)

OBS. *The corolla is commonly marked with ten notches, but there are inſtances in which it has five cleft. Some ſpecies have a funnel-form corolla.*

ESSENTIAL CHARACTER.

Cor. bell-ſhaped, plaited. *Stigmas* two. *Capſ.* two-celled, with two ſeeds in each cell.

SPECIES.

* *With a twining ſtem.*

19. Convolvulus malabaricus.
Lin. spec. 221. *Reich.* 439. *Lour. cochinch.* 108.
Kattu-kelengu. *Rheed. mal.* 11. 105. *t.* 51. *Raii suppl.* 376.
Leaves cordate smooth, stem perennial villose.]

20. Convolvulus canariensis. *Canary Bindweed.*
Lin. spec. 221. *Reich.* 439. *vir. cliff.* 18. *hort. cliff.* 67. *Comm. hort.* 2. 101. *t.* 51. *Pluk. alm. t.* 325. *f.* 1. *Lour. cochinch.* 108.
Leaves cordate pubescent; stem perennial villose; peduncles many-flowered.

[21. Convolvulus muricatus. *Rough-stalked Bindweed.*
Lin. syst. 201. *Reich.* 439. *mant.* 44.
Leaves cordate; peduncles thickened, they and the calyxes even; stem muricate.

22. Convolvulus anceps.
Lin. syst. 201. *Reich.* 439. *mant.* 43. *Vahl symb.* 3. 31.
Leaves cordate; stem keeled on both sides.]

23. Convolvulus Turpethum. *Square-stalked Bindweed, or Turbith.*
Lin. spec. 221. *Reich.* 440. *fl. zeyl. n.* 74. *mat. med.* 61. *Blackw. t.* 397. *Plenck, ic. t.* 105. *Herm. lugdb.* 177. *t.* 178, 179. *Burm. zeyl.* 71. *Raii hist.* 1882.
Turpethum repens, fol. althææ vel indicum. *Bauh. pin.* 149.
Leaves cordate angular; stem membraneous quadrangular; peduncles many-flowered.

[24. Convolvulus grandiflorus.
Lin. syst. 201. *suppl.* 136. *Jacqu. hort.* 3. *t.* 69.
Munda-valli. *Rheed. mal.* 11. 103. *t.* 50.
Leaves cordate ovate blantish quite entire peduncled, bearing about two flowers, calyxes coriaceous; stem and petioles pubescent.

25. Convolvulus maximus.
Lin. syst. 201. *suppl.* 137. *Vahl symb.* 3. 26.
Tiru-tali. *Rheed. mal.* 11. 109. *t.* 53.
Leaves cordate ovate acuminate quite entire very smooth; stem and petioles very smooth.

26. Convolvulus speciosus. *Broad-leaved Bindweed.*
Lin. syst. 201. *suppl.* 137. *Ait. hort. kew.* 1. 211.
C. nervosus. *Burm. ind.* 48. *t.* 20. *f.* 1.
Leaves cordate, tomentose-silky on the lower surface; peduncles longer than the petiole, umbellate; calyxes acute.

27. Convolvulus trinervius.
Lin. syst. 201. *Thunb. jap.* 85.
Leaves cordate oblong smooth three-nerved, stem round; peduncles one-flowered.

28. Convolvulus peltatus.
Lin. spec. 221. *Reich.* 440. *Rumph. amb.* 5. *t.* 157.
Leaves peltate; peduncles many-flowered.]

29. Convolvulus Jalapa. *Jalap Bindweed.*
Lin. syst. 201. *Reich.* 440. *mant.* 43. *mat. med.* 60. *Raii hist.* 724. *Ait. hort. kew.* 1. 211. *Woodv. med. bot.* 59. *t.* 21. *Plenck, ic. t.* 94.

Bryonia mechoacana nigricans. *Bauh. pin.* 298. *prodr.* 135. *Bauh. hist.* 2. 151. *Park. theat.* 179. 7.
Leaves ovate subcordate obtuse obscurely repand villose underneath; peduncles one-flowered.

[30. Convolvulus fericeus.
Lin. syst. 201. *Reich.* 440. *mant.* 43.
C. mollis. *Burm. ind.* 44. *t.* 17. *f.* 1.
Leaves lanceolate-elliptic, tomentose-silky underneath; peduncles subumbellate; calyxes hairy.

31. Convolvulus tomentosus.
Lin. spec. 222. *Reich.* 441. *Sloan. jam.* 1. 154. 12. *t.* 98. *f.* 2. *Raii suppl.* 381. 90. *Pluk. alm. t.* 167. *f.* 4. *Lour. cochinch.* 108.
Leaves three-lobed, tomentose; stem languinose.]

32. Convolvulus althæoides. *Mallow-leaved Bindweed.*
Lin. spec. 222. *syst.* 202. *Reich.* 441. *vir. cliff.* 18. *hort. cliff.* 97.
C. argenteus, althææ fol. *Bauh. pin.* 295. *Mor.* 1. 3. 10.
C. betonicæ althææque fol., repens argenteus. *Barr. rar.* 5. *t.* 312.

C. elegantissimus. *Mill. dict. n.* 22.
C. fericeus. *Vahl symb.* 1. 15. *Forsk. ægypt.* 204.
Leaves cordate sinuate, silky, lobes repand; peduncles two-flowered.

[33. Convolvulus cairicus. *Jagged-leaved Bindweed.*
Lin. spec. 222. *syst.* 202. *Reich.* 441. *Vahl symb.* 1. 15. *Mor.* 1. 7. 6. *Barr. ic.* 30.
C. ægyptius. *Vesl. ægypt.* 73. *t.* 74.
Ipomæa palmata. *Forsk. ægypt.* 43.
Leaves palmate smooth serrulate; stipules leaf-shaped, palmate, axils tomentose; calyxes panicled, even.

34. Convolvulus copticus.
Lin. syst. 202. *Reich.* 441. *mant.* 559. *Retz. obs.* 2. 11. *n.* 16.
C. quinquefolius. *Bauh. pin.* 295. 8. *prodr.* 134. 3. *hg.*
Leaves pedate, serrate; peduncles ensiform, two-flowered; calyxes muricate.

35. Convolvulus vitifolius. *Vine-leaved Bindweed.*
Lin. syst. 202. *Reich.* 442. *mant.* 203. *Burm. ind.* 45. *t.* 18. *f.* 1. *Pluk. alm. t.* 25. *f.* 3.
Leaves palmate five-lobed, smooth toothed; stem hairy; peduncles many-flowered.

36. Convolvulus diffectus.
Lin. syst. 202. *Reich.* 442. *mant.* 204. *Jacqu. obs.* 2. *p.* 4. *t.* 28. *hort.* 2. *t.* 169.
Leaves palmate seven-parted tooth-sinuate smooth; stem hairy; peduncles one-flowered.]

37. Convolvulus macrocarpus. *Long-fruited Bindweed.*
Lin. spec. 222. *Reich.* 442. *Plum. spec.* 1. *ic.* 91. *f.* 1.
Leaves palmate-pedate five-parted; peduncles one-flowered.

38. Convolvulus paniculatus. *Panicled Bindweed.*
Lin. spec. 223. *syst.* 202. *Reich.* 442.
Pal-modecca. *Rheed. mal.* 11. 101. *t.* 49. *Raii suppl.* 374.
β. Modecca. *Rheed. mal.* 8. 39. *t.* 20.
Leaves palmate, lobes seven ovate acute quite entire, peduncles panicled.

39. Convolvulus macrorhizos.
Lin. spec. 223. *Reich.* 443. *Plum. spec.* 1. *ic.* 90. *f.* 1.
Leaves digitate in sevens quite entire; stem smooth; peduncles three-flowered.

40. Convolvulus quinquefolius. *Smooth five-leaved Bindweed.*
Lin. spec. 223. *Reich.* 443. *Swartz obs.* 63. *Pluk. alm. t.* 167. *f.* 6.
Leaves digitate smooth toothed; peduncles even.]

41. Convolvulus pentaphyllus. *Hairy five-leaved Bindweed.*
Lin. spec. 223. *Reich.* 443. *hort. upf.* 39. *Herm. lugdb.* 183. *t.* 185. *Raii hist.* 1881. *Sloan. jam.* 1. 153.
β. C. pentaphyllos, &c. *Plum. amer.* 1. *ic.* 91. *f.* 2.
Leaves digitate in fives hairy quite entire; stem hairy.

[42. Con-

[42. Convolvulus martinicenſis.
Lin. ſyſt. 202. *Reich.* 448. *Jacqu. amer.* 26. *t.* 17. *pict.* 19. *t.* 24. *Locſt. it.* 231.
Leaves elliptic; ſtem creeping ſomewhat twining.

** *Stem not twining.*

43. Convolvulus ſpinoſus.
Lin. ſyſt. 202. *ſuppl.* 137.
C. fruticoſus. *Pall. it.* 2. 734. *t.* M.
Shrubby erect; leaves lanceolate ſilky; flower-bearing branchlets thorny.]

Lin. ſpec. 226. *Reich.* 447. *Browne. jam.* 153. 5. *Plum. amer.* 89. *t.* 104. *Marcgr. braſ.* 51. *Piſ. braſ.* 258.
Leaves emarginate with two glands at the baſe; peduncles three-flowered.

[64. Convolvulus ſublobatus.
Lin. ſyſt. 203. *ſuppl.* 135.
Upper leaves ſloth-repand at the end; ſtem procumbent; flowers in a head.

65. Convolvulus littoralis.
Lin. ſpec. 227. *Reich.* 448. *Plum. ſpec.* 1. *ic.* 90. *f.* 2.
Leaves oblong lobe-palmate; peduncles one-flowered; ſtem creeping.]

Species from other Authors.

66. Convolvulus palmatus.
Mill. dict. n. 8.
C. pentaphyllos, fol. glabro dentato, viticulis hirſutis. *Plum. cat.*
Leaves palmate, lobes ſeven, ſinuate pointed; peduncles one-flowered; calyxes very large ſpreading; ſtem twining.

67. Convolvulus ariſtolochiæfolius.
Mill. dict. n. 9.
C. americanus, Ariſtolochiæ fol. longiore, flor. plurimis in uno pedunculo. *Houſt. Mſs.*
Leaves haſtate-lanceolate, with rounded ears; peduncles many-flowered; ſtem twining.

68. Convolvulus glaber.
Mill. dict. n. 11.

C. fol. oblongis glabris; flor. amplis purpureis. *Houſt. Mſ.*

Leaves ovate-oblong, ſmooth; peduncles one-flowered; calyxes ten-parted; ſtem twining.

69. Convolvulus multiflorus.
Mill. dict. n. 15.

C. americanus, vulgaris folio, capſulis triquetris numeroſis, ex uno puncto, longis petiolis propendentibus, femine lanugine ferruginea villoſa. *Pluk. phyt. t.* 167. *f.* 1.

Leaves cordate, ſmooth; peduncles many-flowered; ſeed villoſe, ferruginous; ſtem twining.

70. Convolvulus hederaceus.
Mill. dict. n. 17. See n. 10.

C. fol. hederaceo anguloſo lanuginoſo, flore magno cæruleo patulo. *Sloan. cat. jam.* 56.

Leaves triangular, acute; flowers many ſeſſile ſpreading; calyxes acute, many-cleft; ſtem twining.

71. Convolvulus roſeus.
Mill. dict. n. 18.

C. americanus hirſutus, fol. acuminato, fl. amplo roſeo. *Houſt. Mſ.*

Leaves cordate, acuminate; peduncles two-flowered; ſtem twining.

72. Convolvulus betonicifolius. (Conf. n. 8.)
Mill. dict. n. 20.

C. exoticus, Betonicæ fol., flore magno albo, fundo purpureo. *Cat. hort. R. Par.*

Leaves cordate-ſagittate; peduncles one-flowered; ſtem twining.

[73. Convolvulus tuguriorum.
Forſt. fl. auſtr. n. 74.

Leaves cordate-ſagittate, acute; ſtem angular, twining; peduncles four-cornered, one-flowered.

74. Convolvulus cæleſtis.
Forſt. fl. auſtr. n. 77.

Leaves cordate, extremely acuminate, pubeſcent; peduncles elongated umbellate-trifid; ſtem twining.

75. Convolvulus mucronatus.
Forſt. fl. auſtr. n. 79.

Leaves palmate-pedate, lobes ciliate mucronate; peduncles one-flowered; ſtem twining.

76. Convolvulus tridentatus. *Trifid Bindweed.*
Lin. ſpec. ed. 1. 157. *Ait. hort. kew.* 208. *Pluk. alm. t.* 276. *f.* 5. *Rheed. mal.* 11. 133. *t.* 65.

Evolvulus tridentatus. *Lin. ſpec. ed.* 2. 392. *Reich.* 751. *Burm. ind.* 77. *t.* 16. *f.* 3.

Leaves wedge-ſhaped three-cuſped, dilated at the baſe, and toothed; peduncles one-flowered; ſtem twining.

77. Convolvulus bufalinus.
Lour. cochinch. 109.

Stem ſhrubby ſcandent, leaves cordate-ſagittate, ſmooth, peduncles many-flowered, anthers ſpiral.

78. Convolvulus aggregatus.
Lour. cochinch. 109.

Leaves palmate ſeven-lobed hairy, flowers aggregate.

79. Convolvulus haſtatus.
Vahl ſymb. 1. 15. *Forſk. ægypt.* 203.

Leaves lanceolate haſtate, peduncles axillary, in pairs, two-flowered.

80. Convolvulus lanatus.
Vahl ſymb. 1. 16.

C. Cneorum. *Forſk. ægypt.* 63. *n.* 124. *catal. arab.* 106. *n.* 120.

C. orientalis humilis argenteus latifolius erectus & villoſus. *Tournef. cor.* 1.

Leaves lanceolate linear tomentoſe, older branches ſpiny, flowers in involucred heads.

81. Convolvulus Hyſtrix.
Vahl ſymb. 1. 16.

C. ſpinoſus. *Forſk. arab.* 106. *n.* 121.

Shrubby, leaves oblong, flowers ſeſſile ſubſolitary, branches ſpineſcent.

82. Convolvulus Imperati.
Vahl ſymb. 1. 17.

C. ſtoloniferus. *Cyrill. rar. neap.* 14. *t.* 5.

Convolvulo marino. *Imper.* 671. (*l.* 28. *p.* 754. *fig.* 767.)

C. marinus Soldanellæ affinis. *Baub. hiſt.* 2. 168.

—major italicus, ſinuato & auriculato folio. *Mor. hiſt.* 2. 37.

Soldanella vel Braſſica maritima major. *Baub. pin.* 295. *Barrel. ic.* 856.

Leaves panduriform or entire, emarginate cordate at the baſe, peduncles one-flowered, ſtem creeping.

83. Convolvulus arenarius.
Vahl ſymb. 1. 18. & 3. 32.

Leaves oblong emarginate lobed at the baſe or entire, peduncles one-flowered, corollas tubular, ſtem twining.

84. Convolvulus Wheleri.
Vahl ſymb. 2. 36.

C. ſagittariæ foliis, flore purpureo Wheleri. *Pluk. phyt. t.* 85. *f.* 3.

Ipomæa ſagittata. *Poir. it.* 2. 160. *t.* 3.

Leaves ſagittate roundiſh behind and entire, peduncles round, one-flowered.

85. Convolvulus lanuginoſus.
Vahl ſymb. 3. 23.

Leaves cordate-oblong ſubhaſtate ſilky-tomentoſe, ears toothed, peduncles three-flowered, ſtem hairy.

86. Convolvulus incanus.
Vahl ſymb. 3. 23.

Silky-tomentoſe, leaves lanceolate ſagittate blunt, ſomewhat toothed at the baſe, peduncles two-flowered.

87. Convolvulus emarginatus.
Vahl ſymb. 3. 23.

C. uniflorus. *Burm. ind.* 47. *t.* 21. *f.* 2.

Leaves lanceolate, the lower ones emarginate mucronate, peduncles one-flowered, outer calycine leaflets ſemiovate, large.

88. Convolvulus filicaulis.
Vahl ſymb. 3. 24.

Leaves linear-lanceolate obtuſe mucronate dilated and toothed at the baſe, calycine leaflets oblong.

89. Convolvulus anguſtifolius.
Vahl ſymb. 3. 24.

Leaves linear haſtate obtuſe mucronate ſmooth, ears almoſt quite entire, peduncles one-flowered.

90. Convolvulus dentatus.
Vahl ſymb. 3. 25.

Leaves haſtate, ſmooth, ears toothed, peduncles many-flowered, muricate.

91. Convolvulus bracteatus.
Vahl ſymb. 3. 25.

Leaves cordate almoſt entire, and three-lobed, haſtate attenuated, peduncles one-flowered, outer calycine leaflets bracte-ſhaped.

92. Convolvulus bicolor.
Vahl ſymb. 3. 25.

Leaves cordate villoſe, angular-ſublobate at the baſe, peduncles one-flowered, outer calycine leaflets bracte-ſhaped.

93. Convolvulus platanifolius.
Vahl ſymb. 3. 26. *Pluk. phyt. t.* 167. *f.* 3. *Feuill. peruv.* 3. 16. *t.* 11.

Leaves cordate three-lobed, ſide-lobes tooth-angular, peduncles ſubtriflorous, and calyxes almoſt equal, ſmooth.

94. Convolvulus acuminatus.
Vahl ſymb. 3. 26.

Leaves cordate and three-lobed, attenuated, peduncles elongated many-flowered and calyxes ſmooth.

95. Convolvulus gemellus.
Vahl ſymb. 3. 27. *Burm. ind.* 46. *t.* 41. *f.* 1.

Leaves cordate, ſomewhat villoſe underneath, peduncles two-flowered.

96. Convolvulus ſtriatus.
Vahl ſymb. 3. 28.

Leaves cordate attenuated ſmooth, peduncles longer than the leaf, having three or four flowers, corollas ſmooth, ſtriated on the outſide.

97. Convolvulus guianenſis.
Vahl ſymb. 3. 28. *Aubl. guian.* 136. *t.* 52.

Leaves cordate-ovate underneath, with the calyxes tomentoſe, peduncles elongated, flowers corymbed in a ſort of head.

98. Convolvulus capitatus.
Vahl ſymb. 3. 28.

Hiſpid, leaves cordate-ovate, flowers in a head.

99. Convolvulus hiſpidus.
Vahl ſymb. 3. 29.

Extremely hirſute, leaves cordate-ovate, flowers umbelled, peduncles very ſhort.

100. Con-

100. Convolvulus parviflorus.
Vahl symb. 3. 29.
Ipomæa paniculata. *Burm. ind.* 50. *t.* 21. *f.* 3.
Leaves cordate acuminate smooth, peduncles many-flowered, and calyxes acuminate villose.
101. Convolvulus violaceus.
Vahl symb. 3. 29.
Leaves and the two outer leaflets of the calyx cordate-ovate, acute, peduncles elongated bifid many-flowered.
102. Convolvulus triflorus.
Vahl symb. 3. 30.
Leaves cordate-lanceolate attenuated smooth obtuse, peduncles three-flowered.
103. Convolvulus bifidus.

Lychnis sylvestris. *Dalech. hist.* 817.
Extremely hirsute, leaves linear, flowers in heads, calyxes acuminate.

DESCRIPTIONS, *&c.*

Stems herbaceous, milky, in the greater part twining, in a very few shrubby. Leaves alternate. Peduncles axillary or terminating, one-flowered, with two bractes, or many-flowered [a].

Gærtner remarks, that it is clear from the structure of the seed, if from nothing else, that the genus *Convolvulus* cannot be referred to the natural order of *Personatæ* with Adanson, or to that of *Campanaceæ* with Linneus; but to a particular family with Jussieu, or else to the *Malvaceæ*, with which the species very frequently agree even in their leafing.

He describes the seed as having a three-fold covering: the outmost very thin, adhering to the seed like black soot; the middle one cartilaginous, thin, of a brown-bay colour; the inmost membranaceous, doubled, with a farinaceous lamina. Albumen thin, farinaceous, extremely white, descending between the folds of the cotyledons, convertible by water into a pellucid jelly. Embryo the size of the seed, curved, yellowish: cotyledons leafy, turned and twisted like a chrysalis: radicle roundish, inferior.

Of this very numerous genus, not above thirteen species are natives of Europe; the others are mostly inhabitants of the warmer climes of Asia and America. Very few of them are common in our gardens except the twelfth and the fifty-sixth; vulgarly known by the names of *Convolvulus major* and *minor*. Mr. Miller has recited thirty-one species in the last edition of his dictionary; but some of these are only varieties, and he had not cultivated them all. No less than thirty-three species are mentioned in the catalogue of the royal garden at Kew. Scammony, n. 3. Jalap, n. 29. and Spanish Potatoes, n. 15. are the most remarkable plants. The two first sorts (arvensis and sepium) are common weeds over the greatest part of Europe.

1. Root perennial, milky, white, the thickness of a crow quill, creeping so as scarcely to be eradicated. Stalks numerous, slender, twisted, procumbent, branched, frequently suffocating plants by twining round them. Leaves alternate, hastate, smooth, running out into two points behind. Petioles shorter than the leaves, on the lower part convex, on the upper channelled. Bractes at a distance from the flower, and sometimes a second, or even a third flower proceeds from the bosom of them. Corolla elegantly variegated with red and white, sometimes wholly white. Seeds angular and brown [b]. —The filaments have sessile glands scattered over them [c]. The claws of the stamens are bearded; and a saffron-coloured gland surrounds the germ [d].

The leaves vary somewhat in shape; and sometimes are very narrow; hence the variety β.—The flowers also are sometimes small, and divided almost to the base; hence the variety γ. It flowers in june and july, in gardens and corn fields, and on dry banks.

Mr. Miller says, it is generally a sign of gravel lying under the surface. He adds, that the roots run very deep into the ground, whence some country people name it *Devil's guts*. [It is called in Yorkshire *Corn-bind*, in other parts *Withwind*, *Bindweed*, *Barebind*, and *Hedge-bells*.

It is the pest of gardens and arable land, and is infinitely more destructive than the next species, because that keeps to the hedges for the sake of climbing, whereas this wanders over whole fields, whence it cannot be rooted out but by repeated ploughings in dry weather, and burning the roots, every atom of which will grow as well as Quich, its rival in creeping.

The blossoms give a deep yellow or orange tincture to water, which is heightened by alum and alkalies [e].

2. Root perennial, white, the thickness of a goose quill, creeping and propagating itself exceedingly, so as not to be rooted out without great difficulty. Stalks numerous, twisted, striated, generally about six feet high, but advancing to ten or twelve, and somewhat branched. Leaves alternate, smooth, petioled, often brown at the edge. Corolla large, white. Nectary a yellow gland, surrounding the base of the germ. Capsule sooty-coloured, pointed. Seeds angular, brown; the cotyledons folded up in a singular manner [f].

Ray observes that it varies with a flesh and rose-coloured corolla; and Linneus, that it has a flesh-coloured corolla in America.—The filaments are hairy. The peduncles are shorter than the petioles; which are above two inches long, smooth, and furrowed above [g]. According to De Necker the peduncle is often double the length of the petiole: and there are globular pedicelled glands on the filaments.

It is easily distinguished from the foregoing, by its superior largeness in every part; the stalks thicker and ramping higher, the leaves three or four inches long, and two or three wide, the peduncles always one-flowered, with a wide double bracte or involucre close under the calyx, commonly of a dusky purple colour, the corollas two inches wide, and milk white. It flowers from july to september, in hedges.

The inspissated juice of the plant, in doses of twenty and thirty grains, is a powerful drastic purge. Can it then be worth while, says Dr. Withering, to import Scammony from Aleppo, when a medicine

[a] Jussieu.
[b] Curtis. [c] Relhan. [d] Haller. [e] Withering.
[f] Curtis. [g] Haller, Pollich, Lyons in Relh. cant.

with

with the very ſame properties grows ſpontaneouſly in many of our hedges? The ſmallneſs of the roots, however, in our common Bindweed, would prevent its juice from being collected in the ſame manner with that which flows on inciſion from the large root of the Scammony, and which by hardening forms that purgative ſubſtance [a].

John Bauhin mentions that ſwine are fond of the roots, and will eat them in large quantities without being purged by them.

3. This is very like the foregoing, but the leaves are not brown about the edge. The peduncles are round, and bear two or three flowers; they are alſo longer than the leaves. The involucre is very ſmall, patulous, remote, not greater than the calyx, erect and approximating. The calyx is dilated on the ſides and emarginate, not round, and acuminate.] Corolla pale yellow. Seeds ſmaller than thoſe of the preceding ſort. Capſule three or four-celled.

[Native of the Levant, and the woods of Cochinchina.

The roots are three or four feet long, and from nine to twelve inches in circumference, covered with a light-gray bark, tapering, branched at bottom, and containing a milky juice.

Martinelli, an apothecary of Venice, travelled into Syria, in order to procure the true Scammony, and ſent over the ſeeds, which were ſown, and grew at Padua and Antwerp. *Pena* 1561 *or* 1562.

Monſ. Richard, gardener to the King of France at Trianon and Verſailles, ſent the ſeeds to Mr. Miller in 1753; theſe he ſowed in the open ground, and they ſucceeded very well, producing flowers in june, july and auguſt, and ripening the ſeeds in ſeptember [b]. But it was cultivated before in 1596, by Gerarde [c].

Scammony is a gummy reſin obtained from the milky juice of the root, by clearing away the earth from the upper part of it, and cutting off the top in an oblique direction about two inches below where the ſtalks ſpring from it; then under the moſt depending part of the ſlope, a ſhell, or other convenient receptacle, is fixed for the juice to run into. This juice gradually hardening, is the genuine Scammony. It is brought from Aleppo and Smyrna. Scammony appears to have been well known to the Greek and Arabian phyſicians, who uſed it for various other purpoſes, as well as by way of a purgative. It is a ſtimulating Cathartic; but ſomewhat uncertain in its operation. The doſe is generally from three to twelve grains. It is frequently, and indeed generally employed in compoſition with other ingredients.

4. Root annual. Stem ſix feet high, even, two-angled from the decurrent ſtipules, but not ancipital. Leaves ſcarcely repand, quite entire, ending in a point the length of the leaf, paler underneath, and veined. Petioles half the length of the leaves, channelled above. Stipules ſmall, vertical. Peduncles two-cleft, two-flowered, ſhorter than the leaf. Calyx ovate, cloſe, without bractes. Corolla whitiſh, or having a ſhade of fleſh-colour, with a yelloviſh bottom, like that of *Convolvulus arvenſis*, but only half the ſize, and plaited. Stamens half the length of the corolla, with yellow anthers. Native of Siberia [d].

Introduced 1779, by Meſſrs. Kennedy and Lee.

It flowers in july and auguſt [e].

5. Root annual. Stem ſix feet high, round, covered with a very fine meal. Leaves cordate or ſagittate, very obtuſe behind and emarginate, with a repand edge (ſcarcely eroſe) naked, wrinkled above, veined underneath, the ſinus of the baſe obtuſe, very acuminate, twice as long as broad. Petioles half the length of the leaves, mealy. Stipules ſcarcely any. Peduncles three-flowered, longer than the leaves. Calyx round, cloſe. Corolla three times the ſize of the calyx, ſomewhat fleſh-coloured, acute, five-cleft. Stigmas oblong [f].

[a] Curtis. [b] Mill. dg. [c] Hort. kew.
[d] Linn. mant. [e] Hort. kew. [f] Linn. mant.

Perennial. Native of Madeira. Flowering in may and june. Introduced 1777, by Mr. Francis Maſſon [g].

6. Allied to *C. reptans* (n. 58.). Stem twining, not rooting. Leaves lanceolate, ſmooth, acute, entire, dilated at the baſe into two recurved ears, ſomewhat toothed outwardly. Peduncles ſeldom two-flowered: Two lanceolate, acuminate bractes on the middle of the peduncle. Leaflets of the calyx ſagittate, as in *Campanula Medium*. Native of the Eaſt Indies [h]. Introduced 1778, by Mr. William Roxburgh. It flowers in july and auguſt, and is annual [i].

7. Stem filiform, ſimple, ſmooth. Leaves alternate, moſtly on one ſide, petioled, ſmooth; the middle lobe lanceolate, quite entire, acute, an inch in length; the ſide ones a little reflected, having one tooth behind, which is ſometimes ſhort, ſometimes half the length of the lobe; theſe are half an inch in length. Petioles filiform, reflected, ſmooth, three times the length of the leaves. Flowers axillary, ſolitary, on a peduncle the length of the leaf, filiform, ſmooth. Leaflets of the calyx ovate, acute, entire, ſmooth.—Native of Japan, where it is alſo cultivated. It flowers from may to july [k].

8. Root perennial, thick and long like that of a carrot. Stems very long and ſlender. Leaves various; the lower and upper entire, reſembling thoſe of the kidney-bean; the middle ſinuate, and ſome deeply angular: the upper leaves, and thoſe which ariſe from the axils of the larger ones are ſmooth, but the middle and lower leaves are covered with a fine lanugo, perceptible to the touch rather than the ſight. Peduncles long, ſlender, ſuſtaining from one to three flowers, large and white, with the bottom of a fine purple. Capſule two-celled and two-ſeeded. Seeds hirſute.—Native of Carolina, whence the ſeeds were ſent to Dr. Sherard, and cultivated in the Eltham garden [l].—Alſo in Virginia. It flowers from june to ſeptember.

9. Stems ſlender, reddiſh towards the root, and at the joints hairy. Leaves ſome entire and cordate, others like ivy leaves. Peduncles near an inch in length, with a few narrow bractes. Corollas pale purple, of the ſame form and ſize with thoſe of *C. arvenſis*. Capſule globular, hairy at top, two-celled, four-valved, with two ſmooth, brown ſeeds in each cell. Cultivated in the Eltham garden, from ſeeds ſent among rice from Carolina [m].

10. This differs from the next ſpecies, which it otherwiſe very much reſembles, in having the upper leaves, and ſometimes the lower entire, whereas in that they are all angular; the flowers alſo are much larger: they are ſolitary, on very ſhort peduncles; of a very elegant blue colour, with a whitiſh baſe. Calyxes hairy [n]. Capſule ſpherical, ſmooth, thin, three-celled, three-valved: there are two ſmall ſcars at the baſe of the central angle of the cells. Seeds two in each cell, convex on one ſide, angular on the other, attenuated towards the baſe, black and ſmooth [o]. It is an annual plant, and grew in the Eltham garden from ſeeds brought by a ſlave ſhip from the river Gambia in Africa. Some Bengal ſeeds produced a Convolvulus reſembling this, but having flowers only of half the ſize.

Another plant figured in t. 83. f. 96. from Mexico, is probably not different from this. The calyxes are remarkably rough, and marked with many black tubercles, as in the *purpureus*; the peduncles are four or five-flowered [p].

The peduncles, even of the fruits, are erect, according to Linneus, and are the ſame length with the petioles. Native of Aſia, Africa and America.]

11. This alſo is an annual plant, riſing with a twining ſtalk eight or ten feet high. Leaves woolly, ending in ſharp points, and on long petioles. Each peduncle ſuſtains two flowers of a very deep blue colour, whence its name of Anil or Nil (Indigo).

[g] Hort. kew. [h] Linn. ſpec. [i] Hort. kew.
[k] Thunberg. [l] Dillenius. [m] Ibid. [n] Ibid.
[o] Gærtner. [p] Dillen.

[Linneus remarks, that the peduncles are very ſhort, and the fruits erect.]

This is one of the moſt beautiful of the genus. Some have ſuppoſed it to be only a variety of the twelfth ſort; but the leaves have three deeply divided lobes, whereas in the other they are entire. It flowers all the latter part of the ſummer, and in good ſeaſons the ſeeds ripen well in the open air.

[It is a native of America, and was cultivated before 1597, by Gerarde [a], but periſhed before it ripened its ſeeds. "He ſays, that it is called of "the Arabians *Nil*: of Serapio *Hab al Nil*: about "Alepo and Tripolis in Syria, the inhabitants call "it *Haſmiſen*: the Italians *Campana azurea*, of the "beautiful azured flowers, and alſo *Fior di notte*, "becauſe his beauty appeareth moſt in the night." This ſpecies is now rarely met with in our gardens [a].

12. Peduncles erect, but the pedicels of the fruit thickened and drooping; the calyx dotted-ſcabrous and hairy [b].] It is commonly known in the gardens by the name of *Convolvulus major*. There are three or four laſting varieties of it; the moſt common has a purple flower, but there is one with a white, a ſecond with a red, and a third with a whitiſh blue flower and white ſeeds. Theſe plants, if properly ſupported, will riſe ten or twelve feet high: they flower in june, july and auguſt, and will continue till the froſt kills them. Their ſeeds ripen in autumn.

[Native of America.

Sent out of Italy, and cultivated in England 1629 [c].]

β. In Jamaica, where it grows naturally, this ſends out long branches, which twiſt about the trees, and riſe to a great height. The leaves are ſmooth, heart-ſhaped, ending in long points, the ears at the baſe are large and rounded, and the petioles are long and ſlender. The peduncles are long, each ſuſtaining three flowers: the corolla is of a deeper purple, and the tube is longer than in the other. It flowers from the end of june till the froſt deſtroys it.

[γ. Stems ſlender, with a tinge of duſky purple. Leaves ſomewhat hairy; peduncles two inches long, hairy, bearing one or two flowers on pedicels half an inch in length. Corolla bright blue, with a whitiſh baſe. Calyx warted and hairy, with ſome ſlender bractes at the baſe.—The leaves in this variety are only half the ſize of the firſt, and the flowers are much ſmaller; when the corolla fades it breaks into five pieces, which the other ſeldom does. Cultivated in the Eltham garden from ſeeds ſent by Bern. de Juſſieu, who received them from the banks of the Miſſiſippi [d].

δ. The leaves of this are ſmaller than ſ. 96. ſee n. 10. and the hairs ſo few and inconſiderable, that they appear to be ſmooth. The flowers are fewer, deeper coloured, and ſomething larger; the whole plant is leſs, and does not riſe ſo high, but the principal difference is, that the calyxes are not dotted.—It is lower, the leaves leſs and ſmooth, the flowers ſmaller than in the firſt of theſe, and of a violet colour.—It grew in the Eltham garden from ſeed that came among rice from Carolina [e].

Theſe varieties are all annual.

13. Stem pubeſcent. Leaves villoſe-ſcabrous. Native of Java [f].

14. Root annual. Stem round. Leaves exactly cordate, ſomewhat villoſe underneath, ſcabrous about the edge; the petioles ſubpubeſcent. Peduncles longer than the petioles, ſubpubeſcent, thicker at top and ſmooth; with two obſcure bractes. Corolla as in n. 10. but leſs, and different in colour [g].

Stems, according to Dillenius, many, ſlender, three feet high and upwards, ſmooth at bottom, but hairy at top. Corolla nearly the ſize of *C. arvenſis*, white with a tinge of yellow and a purple eye. Fruits reflected.—It grew in the Eltham garden from ſeeds ſent from Batavia; and flowered in auguſt [h].

[a] Hort. kew. [b] *Curtis.* [c] Linn. ſpec.
[d] Park. parad. [e] Dillenius. [f] Ibid.
[g] Linn. mant. [h] Linn. ſpec. [i] Dillenius.

Native of China, Cochinchina, Batavia, Ceylon and Surinam.

15. Stem round, perennial, hiſpid, proſtrate, creeping, putting forth ſcattered, oblong, acuminate tubers, purple or pale on the outſide. Leaves angular, on long petioles. Flowers purple, lateral, large, three or thereabouts together, on upright peduncles [i].

Native of both Indies, alſo of China, Cochinchina, &c. But it is affirmed, that it was unknown in the Philippine and Molucca iſlands before the Spaniards brought it there. In Amboina, Banda, Ternate, &c. the inhabitants add *Caſtela* to the name, as having derived it from the Caſtilians or Spaniards. Gerarde cultivated it in 1597. He calls theſe roots *Potatus*, *Potades*, or *Potatoes*, and ſays that they are by ſome named *Skyrrits of Peru*. He bought the roots at the exchange in London, and they flouriſhed in his garden until winter, at which time they periſhed and rotted. Neither he, nor Parkinſon, nor any of the old botaniſts were acquainted with the fructification, inſomuch that Cluſius could not learn whether this plant bore flower or fruit; and Margraaf affirmed that it had none. Ray ſagaciouſly conjectured the *Batatas* to be a *Convolvulus*. It came firſt into Spain from the Weſt-Indies or the Spaniſh Main. The roots are annually imported into England from Spain and Portugal. They were the common Potatoes of our old Engliſh writers, the roots which are now ſo generally cultivated among us under that name being then little known.

The roots of Battatas or Spaniſh Potatoes are ſweet, ſapid, and eſteemed nouriſhing. They are very commonly cultivated in all the tropical climates; where they eat not only the roots, but the young leaves and tender ſhoots boiled.

There are probably ſeveral varieties, if not diſtinct ſpecies of Battatas. Loureiro mentions one under the name of C. mammoſus: the Battata mammoſa of Rumphius amb. t. 131.—The ſtem is ſlender, twining, annual. Leaves cordate, repand, acuminate, ſmooth, with the ribs oblique. Flowers white, two or three on a peduncle. The roots are in bunches, pale brown, hairy, ovate-oblong, frequently acuminate, white within, of a tougher ſubſtance, but not ſo ſweet as the common ſort, yet more eſteemed among the natives.

Forſter (eſcul. p. 56.) mentions a ſecond, which he took for a variety, but Solander had named it C. chryſorrhizus; the root is large, and of a dark orange colour within. It is found not only in the South ſea iſlands within the tropics, but alſo in Eaſter iſland, and in the northern parts of New Zealand. See alſo n. 93.

16. Root annual. Stem round, hairy, branched at the baſe, of the ſame ſize as in *C. arvenſis*. Petioles round, hairy, ſhorter than the leaf. Peduncles rough with hairs, in pairs, approximating at the baſe almoſt into one, ſhorter than the petiole. Calyx five-leaved, the two outer leaflets cordate-oblong, the two inmoſt linear-lanceolate, the fifth ſemicordate. Corollas white, five-cleft, ſmall, the lobes three-cleft, the middle cleft ſmalleſt: tube ſhorter than the calyx. Stamens the length of the tube. Piſtill white, the length of the ſtamens: ſtigmas two, headed, purple. Native of China [k].

17. The corolla is bell-ſhaped, as in moſt flowers of this genus, not cut as in Plumier's figure. The leaves are cordate or ovate, with the edge ſomewhat repand and roughiſh. The flowers are blueiſh and ſmall: the peduncles ſhorter than the leaf, umbellate, but the lateral pedicels are often ſubdivided.—Native of America [l].

18. Stem herbaceous, twining, filiform, ſtiff, ſubdivided, pubeſcent, round. Leaves above two inches long, and as broad at the baſe, deeply cordate, lanceolate, angles of the baſe rounded, edge ſubrepand entire, ſubtomentoſe, dark green, hoary beneath; petioles three inches long, thickiſh, round. Flowers

[i] Loureiro. [k] Linn. ſpec. [l] Ibid.

many, terminating on peduncles three inches long or more; partial peduncles three quarters of an inch in length, three-flowered, each flower on a pedicel much longer than the partial peduncles. Corollas yellow, the border plaited, obtufely pentangular. Two leaflets of the calyx a little ſhorter than the reſt. Anthers whitiſh oblong. Germ oblong; ſtyle ſimple: ſtigmas two, globular. Capſule two-celled, with one ſeed in each cell, black, angular-roundiſh, velvet-villoſe [a].

Native of the Weſt-Indian iſlands. It flowers in june and july. Introduced 1774, by George Young, M. D. [b].

19. Stem perennial, twining, round, ſlender, villoſe. Leaves acuminate, quite entire. Peduncles one-flowered. Corolla bell-ſhaped, with a long tube, white, with a duſky purple baſe [c].

Native of the Eaſt-Indies and Cochinchina.]

20. Roots ſtrong, fibrous. Stems woody, branched, growing twenty feet high and more when ſupported. Flowers axillary, ſeveral on one peduncle, for the moſt part of a pale blue, but ſometimes white. It flowers in june, july and auguſt, and ſometimes ripens ſeeds here. Native of the Canary iſlands, [Cochinchina, &c.

Cultivated 1690, by the Dutcheſs of Beaufort [d].

21. This bears a great reſemblance to *C. purpureus*, but the ſtalk is very ſmooth, and has harmleſs prickles ſcattered over it. Leaves undivided. Peduncles uſually two-flowered. Corolla purple, more funnel-ſhaped than in *C. purpureus*. It is a different ſpecies from *Ipomœa bona nox*.—Native of Suratte [e]. It is annual; flowers in july and auguſt, and was introduced by Daniel Charles Solander, L. L. D. [f].

22. Stem ſmooth, keeled on each ſide from leaf to leaf, or winged with two decurrent membranes. Leaves three inches long, ſmooth, veined, obtuſe, quite entire, on petioles nearly the length of the leaf. Peduncles axillary, of the ſame length with the petioles, but thicker, bearing four or five flowers. Pedicels thickened, ſubumbelled, villoſe, as are alſo the peduncles. Two bractes at the baſe of the calyx, broad, ovate, membranaceous, mucronate, villoſe, deciduous. The two outer leaflets of the calyx ovate, villoſe on the outſide, ſmooth within, mucronate; the inner only half the ſize, oblong. Corolla twice as long as the calyx, bell-ſhaped. Stigma capitate [g].

Native of Ceylon and Java.]

23. Root perennial, having thick fleſhy tubers, ſpreading far in the ground, and abounding with a milky juice which flows out when they are broken or wounded, and ſoon hardens into a reſinous ſubſtance, when expoſed to the ſun and air. Theſe put forth many twining branches. The leaves are ſoft like thoſe of Marſh-Mallow. The flowers are produced at the joints on the ſide of the ſtalks, ſeveral together on the ſame peduncle: they are white, and ſhaped like thoſe of the common great Bindweed (n. 2.) They are ſucceeded by round capſules, having three cells, which contain two ſeeds in each.

[Stems quadrangular, winged. Leaves bluntiſh, ſometimes angular; petioles ſemicylindric, half the length of the leaf. Peduncles ſubcylindric, trifid; pedicels ſubuniflorous. Corolla white, ſcarcely twice as long as the calyx, bell-ſhaped, plaited, five-cleft. The two outer leaflets of the calyx are ovate and villoſe, hence probably Linnæus attributes a two-leaved involucre to each flower; the three inner ones are ovate and ſmooth. Anthers ſpiral. Stigma globular-two-lobed. Capſule membranaceous, globular-depreſſed, two-celled, with one or two roundiſh, black ſeeds, angular on one ſide, in each cell.

Native of Malabar, of the iſland of Ceylon, and of the Society and Friendly iſles, and the New Hebrides in the South Seas [h].

Cultivated 1759, by Mr. Miller [i].

[a] Swartz. [b] Hort. kew. [c] Loureiro.
[d] Hort. kew. [e] Linn. mant. [f] Hort. kew.
[g] Vahl. [h] Forſter. [i] Hort. kew.

24. Stem arboreous, at firſt erect, then twining, pubeſcent. Leaves large, with rounded lobes; obtuſe, ſmooth, on pubeſcent petioles. Flowers large. Calyx two or three-leaved, coriaceous. Native of the Eaſt-Indies [a].

25. Stem woody at bottom, then twining, and mounting to a great height. The whole plant very ſmooth. Native of Ceylon [b].

26. Stem arboreous, erect, then twining, round, pubeſcent. Leaves very large, hairy on the upper ſurface, covered with a white down on the lower, and ſhining like ſilver in the ſun-ſhine; the lobes rounded, and very obſcure. Petioles round and pubeſcent [c].

Native of the Eaſt-Indies.—Introduced 1778, by Sir Joſeph Banks, Bart. [d].

27. Stem filiform, ſmooth, ſimple. Leaves oppoſite, petioled, acuminate, quite entire, paler underneath, an inch or ſomewhat more in length. Petioles linear, ſmooth. Flowers ſolitary or in pairs, ſubſeſſile. Diviſions of the calyx lanceolate-ſetaceous, ſmooth, half the length of the corolla, which is purple. Native of Japan [e].

28. Native of Amboina, and the Society iſles.]

29. Root large, oval, full of milky juice. Stems many herbaceous triangular twining, eight or ten feet high. Leaves varying in ſhape, cordate, angular, or oblong and pointed; they are ſmooth, and ſtand on long petioles. Flowers ſhaped like thoſe of the common great Bindweed (n. 2.); reddiſh on the outſide, but dark purple within; probably varying in colour. Seeds covered with a very white down like cotton.

Native of South America, as at Xalapa between La Vera Cruz and Mexico. Dr. Houſtoun brought ſome of the roots to Jamaica, and planted them there, with a deſign of bringing this uſeful plant into cultivation; but they were neglected and loſt ſoon after he left the country.

[It was cultivated here a few years before 1768, by Mr. Miller: and was introduced into Kew garden in 1778, by Monſ. Thouin [f]. It is ſaid that the root was firſt brought to Europe about the year 1610.

The medicinal virtue of Jalap reſides in the reſin. The powdered root is the part uſed. It is in general a ſafe and efficacious purge; in large doſes it has been much celebrated as a hydragogue in dropſies. It is often preſcribed in a compound form, as with cream of tartar, &c. The doſe of the ſimple powder is commonly from one ſcruple to two.

30. Stem ſhrubby, ſmoothiſh. Leaves alternate, petioled, underneath ſhining, marked with lines, acute. Peduncles axillary, the length of the petioles, umbelliferous, uſually with five flowers; and with an ovate ſilky involucre. Calyxes extremely hairy.—Native of the Eaſt-Indies [g]. Loureiro ſeems to have made a new genus of this under the name of Argyreia.

31. Stem round, whitiſh, climbing twenty feet high. Leaves like the older leaves of ivy, an inch and half in length and breadth; petioles three quarters of an inch long. Flowers axillary, ſolitary; peduncles a quarter of an inch in length. Corolla of a fine purple colour, with five paler ſtreaks. Capſule ſpheroidal, acuminate, two-celled, with one black ſeed in each cell.—Native of Jamaica, China and Cochinchina [h].]

32. Root perennial, ſending out many weak twining ſtalks, about three feet high when ſupported, and if not, lying on the ground. Leaves of different forms, ſome almoſt like thoſe of Betony, and ſlightly cut on the edges, others almoſt heart-ſhaped and deeply cut, ſome to the midrib; they ſhine like ſattin, are ſoft to the touch, and ſtand on ſhort petioles. Peduncles very long, two-flowered, corolla pale roſe-colour. It flowers from june to auguſt, but rarely ripens ſeeds in England.

[Native of the Levant, county of Nice, &c.]

[g] Linn. mant. [h] Sloane & Loureiro.

β. This

β. This has many ſlender ſtiff ſtalks, twiſting about other plants to the height of five or ſix feet. Leaves divided into five or ſeven narrow lobes. Corolla pale roſe-colour, with five ſtripes of a deeper red. [This variety is more tender, the corolla ſmaller, the outer leaves of the calyx not hairy, and the leaves more denſely villoſe[f].

The plant in a wild ſtate has one-flowered pedundles[g].

Cultivated 1656, by Mr. John Tradeſcant, jun.[h]

33. The whole plant is ſmooth except the axils which are cloſely hairy. Leaves ſeven-cleft: clefts lanceolate, ending in a dagger point, the ſide ones ſhorter. There is a leaflet on each ſide at the baſe of the petiole, of the ſame ſtructure with the leaves on the ſtem. Peduncles twice as long as the leaf. The pedicels have two bractes about the middle. The calycine leaves are ſmooth and blunt. The corolla bell-ſhaped. The ſtigma capitate[i].

Native of Egypt. Introduced 1770, by Monſ. Richard. It flowers in june and july[k].

34. Stem herbaceous, angular, ſmooth and even. Leaves petioled, ſmooth and even; the leaflets lanceolate, ſerrate; the ſide ones gradually ſhorter. Stipules very like the leaves, only ſmaller. Petioles channelled, ſcabrous underneath. Peduncles axillary, compreſſed, ancipital or enſiform; with two minute bractes. Calyx rather oblong, acute, muricated. Corolla white, acute. Stigma blood-red.—The foregoing ſpecies has the leaves more pinnatifid and ſerrate: the corollas twice as big, and purple: the calyxes ſmooth and even: the peduncles filiform and panicled; the petioles filiform, but the ſtipules almoſt as in *C. capticus*.—Native of the Levant[l].

König ſent a plant under this name, and agreeing with this deſcription, except that the ſtems are only a ſpan high or ſhorter, proſtrate, not twining. Leaves rather palmate or five-lobed almoſt to the baſe. Peduncles ſcarcely compreſſed. Bractes like the leaves in form and ſize, only the diviſions ſomewhat narrower. Capſules large in proportion to the ſize of the plant.—Retzius doubts whether it be a diſtinct ſpecies[m].

35. Leaves divided to the midſt, the diviſions acuminate. Racemes two-parted. Calyxes villoſe. *Native of the Eaſt Indies.*

36. Leaves divided almoſt to the baſe. Calyx ſmooth.—Native of America[n].

37. Peduncles jointed, thickened, plaited.—Native of South America[o].

Annual. It flowers in july and auguſt. Cultivated 1752, by Mr. Miller[p].

38. It varies with three or five-lobed leaves.—In the ſands of Malabar[q].

39. Native of America.

40. Stem herbaceous, twining, filiform, round, hirſute. Leaves ſubpedate in fives, digitate, the two inner diviſions ſmaller, lanceolate, acute, ſerrate, nerved, veined, ſmooth on both ſides: petioles round, recurved, pubeſcent, ſhort. Peduncles axillary, ſolitary, twice as long as the leaves, three-flowered, erect, pubeſcent; pedicels one-flowered. Calycine leaflets oblong, permanent, ſmooth, pale, the three inner ones larger. Corolla bell-ſhaped, white, tube narrower at the baſe, ſwelling in the middle; border five-cornered, plaited, ſpreading. Capſule roundiſh, two-celled, two-ſeeded.—Native of Jamaica[r].]

Mr. Miller deſcribes it as having a woody ſtalk covered with a purple bark, and twining about trees to the height of thirty feet or more. Leaves deeply divided into five ſharp-pointed lobes. Flowers on long thick peduncles, which have a knee in the middle; they are very large, and of a purple colour. Capſules round, as large as a middling apple, divided into three cells, each containing two ſmooth ſeeds. It grows about Tolu in New Spain, whence the ſeeds were ſent by Mr. Robert Millar. [This muſt be a different plant.

41. Leaflets quite entire, pedicelled. Peduncles long, branching. Flower white. Two large bractes include the calyx. Two obtuſe ſtigmas. Capſules obtuſe. Annual.—Native of the Weſt Indies[s].

It flowers in auguſt and ſeptember. Cultivated 1759, by Mr. Miller[t].

The deſcription of C. pentaphyllus by Miller (dict. n. 12.) does not at all agree with the above.] He ſays it is perennial, and riſes with ſtrong winding ſtalks to the height of twelve or fourteen feet; that the leaves are divided into five lobes and ſtand on ſhort footſtalks; that the peduncles are long, each ſuſtaining two purple flowers; and that the ſtalks, leaves, and every part of the plant, are cloſely covered with pungent ſtinging hairs, of a light brown colour. He received the ſeeds from Carthagena in New Spain.

[He gives Plumier's name in variety β. to his 8th ſpecies, which he calls *C. palmatus*.

42. Stems round, ſmooth, proſtrate, long, rooting, twining a little. Leaves elliptic, blunt with a point, quite entire, ſmooth, petioled, two inches long. Peduncles one-flowered, axillary, ſolitary, three inches long, with two oppoſite ſmall bractes at top. The three outer calycine leaflets ovate, acute, very large and looſe; the two inner much ſmaller, lanceolate, acute. Corolla white.

Native of Martinico[u].

43. Stem ſubflexuoſe, ſcarcely twining, the whole white with very ſhort ſhining hairs. Leaves oblong or lanceolate, ſeſſile. Stems branching at top, the branches horizontal, rigid, terminated by one, erect, ſmall, whitiſh flower. The rudiments of branch-lets in the axils of the branch-leaves are changed into ſhort ſpines. It has the air of *C. Cneorum*.—Obſerved by Profeſſor Pallas on the ſandy hills by the river Irtis in Siberia[x].]

44. This is an annual plant, riſing about two feet high, with ſlender twining ſtalks. The flowers are ſmall, of a blueiſh colour, and have little beauty.

[The ſtem is very little or ſcarcely twining; uſually not at all[y].—Native of the South of Europe. It flowers in june, and was cultivated by Mr. Miller in 1739[z].

45. The herb of this ſpecies very much reſembles *C. tricolor*, but it is ſmaller. Leaves ſubpetiolate. Flowers axillary, on very ſhort peduncles. Bractes ſcarcely any, only there are frequently two obſcure ſcales. The corolla has the ſtructure of *C. lineatus*, but is only one-third of the ſize; it is blue with a yellow throat; the border almoſt five-parted, with acuminate diviſions.——Native of Majorca, and annual[a].

In a poor ſoil, it varies with ſimple, filiform ſtems, a finger's length, and ſomewhat hairy towards the top: the leaves narrow, but widening at the end, the upper ones linear and ſharp; the lower flowers peduncled, the upper ſeſſile; the calyxes ſomewhat hairy[b].

46. Stems from four to ſix inches high, proſtrate, flexuoſe. Leaves remote, narrower at the baſe, acute. Peduncles ſhorter than the leaf, with two bractes longer than the calyx. Calyxes ſomewhat leafy, not hairy, but obſcurely ſilky. Corollas very hairy on the outſide[c.] The flowers are produced on the ſide and at the top of the ſtalks, in ſmall cluſters, ſitting cloſe together; they are much ſmaller than thoſe of *C. Cantabrica* (n. 48.), but of a deeper roſe-colour. The root is perennial and creeping.

[Native of the coaſts of France, Nice, Spain, and Sicily. Cultivated 1714, by the Dutcheſs of Beaufort[d].]

47. Stems ſhrubby, upright, about three feet high. Leaves lanceolate, blunt, ſilky, placed cloſely on every ſide the ſtem; they are near two inches long, and a quarter of an inch broad. The flowers

are

are produced in clusters at the top of the stem, sitting very close; they are of a pale rose-colour, and come out in june and july, but do not perfect seeds in England.

[The stem is terminated with a four-leaved five-rayed umbel; the central peduncle one-flowered, leafless, the lateral ones four or five-flowered. Two bractes below the forks, and two under each alternate flower. Calyxes obtuse, hirsute, as the bractes[e]. Native of Spain, Italy, Sicily, and the Levant.

Cultivated in 1739, in the botanic garden at Chelsea[f].

48. Root perennial, about the thickness of a quill, of a dirty brown colour, running deep into the ground. Stems several, annual, hirsute, round, half a foot high or more, slender. Leaves narrow oblong, thickish, pale green, hairy on both sides, entire, alternate; the root-leaves blunter and narrowing into a ciliate petiole; stem-leaves acute and sessile. Peduncles axillary, solitary, from one to three inches long, villose, sustaining two or three flowers on short pedicels. Calyx hirsute, divided into lanceolate acute segments. Corolla flesh-coloured or pale rose-coloured, with five broad red lines, which are hairy on the outside. Anthers pale. Stigmas two filiform. Capsule smooth, roundish, two-celled, with two brown seeds in each cell[g]. It varies much in size (Mr. Miller says it is from two to three feet high), but it may easily be known by its straight stem a little inclined, its villose white leaves and calyx, and pale purple flowers rolled in a spiral. It is fond of warm rocky situations[h].

Native of the South of Europe. Cultivated in 1743, by Mr. Miller[i].

49. Stem panicled. Leaves sublanceolate, silky, on the upper branches smaller and fewer. Branches rigid, seldom dichotomous, terminated with flowers usually solitary. Shrubby.—Native of the Levant[k].]

50. Root perennial, sending up several erect branching stalks about two feet high. The flowers come out singly on the side of the stalks, sessile, of a pale blueish colour, and spreading open almost to the bottom.

[It has the appearance of Broom, not of *Convolvulus*. Stem round, very smooth. Branches quite simple, erect, leafy. Leaves alternate, remote, short, slender, erect. Racemes terminal, with the flowers mostly on one side. Peduncles alternate, solitary, remote, mostly three-flowered, seldom one-flowered, bracted. Corolla white, hairy on the outside. The wood is white and hard, with radiating streaks: when scraped it has the smell of Roses; it has also a slight acrid taste. *Qu.* whether it be the *Lignum Rhodium* of the shops?—Found about Santa Cruz, by Masson[l]. Mr. Miller says, it grows in Candia, and several islands of the Archipelago.

Native of the Canary islands. Cultivated 1768, by Mr. Miller[m].

51. This has the air of *Oenothera molliſſima*. Stems woody, round, reddish, somewhat glaucous. Leaves narrow, the length of the finger, lax, flat. Peduncles at the top of the stem, short, angular. Bractes in pairs, recurved, subulate. Calyx consisting of five, acute, very smooth, somewhat spreading, hoary leaves, membranaceous about the edge. Corolla funnel-shaped, large, tawny-coloured.—Found at the Cape of Good Hope, by Sparmann[n].

52. This resembles *C. Cneorum*. Stems woody, procumbent. Branches erect, stiff, hoary. Leaves petiolate, linear, entire, waved, veined, smooth. Peduncles from the axils of the upper leaves, branched continually, so as to form a large ovate or thyrsoid panicle. Flowers very numerous, small. Leaflets of the calyx ovate, concave, acute. Corolla pale red, hirsute on the outside[o].

Native of the Canary islands. Mr. Francis Masson.

[e] Linn. syst. [f] Hort. kew. [g] Jacquin. [h] Vahl. [i] Hort. kew. [k] Linn. spec. [l] Linn. suppl. [m] Hort. kew. [n] Linn. suppl. [o] Ibid.

Introduced 1779. It flowers in auguſt and ſeptember[p].

53. Native of America, and New Caledonia.

54. Native of Virginia.

55. The whole plant is tomentose, like *Verbaſcum* or Mullein. The corolla is white.——Native of Persia, on the shore of the Caspian[q].

56. This is an annual plant, with several thick herbaceous stalks, about two feet long, not twining but bending towards the ground, upon which many of the lower branches lie prostrate. Leaves sessile. The peduncles come out just above the leaves at the same joint, and on the same side; they are about two inches long, each sustaining one large open bell-shaped flower, of a fine blue colour with a white bottom, varying to pure white, and sometimes beautifully variegated with both colours. The white flowers are succeeded by white seeds; but in the blue ones they are dark-coloured.

[Native of Barbary, Spain, and Sicily. (Mr. Miller says Portugal). Cultivated 1629, by Parkinson[r]; who received the seeds (as he says) out of Spain and Portugal, from Guillaume Boel.

It is known among the seedsmen and gardeners by the name of *Convolvulus minor*.

[Mr. Curtis observes, that the whole plant with us is in general hairy, and hence that it does not well accord with Linneus's description. Parkinson's figure is very hairy, but Mr. Curtis's is perfectly smooth.]

57. Root perennial. Stems strong, smooth, winding, extending wide, and putting out roots at the joints. Flowers large, sulphur-coloured, on long peduncles from the side of the stalks, each supporting one flower, with a large swelling calyx. Capsule large, smooth, oval, three-celled, with one large smooth seed in each.—Native of America near the sea. Mr. Miller received the seeds from Campeachy.

[Swartz describes the stem as creeping, jointed, rooting, angular, compressed, subdivided. Leaves terminating, crowded, oblong, sometimes bluntly sagittate, entire, emarginate, scarcely veined, very smooth, somewhat succulent, on longish petioles. Peduncles from the axils of the terminating petioles, the length of the leaves, erect, one-flowered. Flowers rather large, whitish.—Native of the sandy coasts of Jamaica.

58. One of the smaller plants. Stem filiform, smooth and even. Leaves cordate, hastate, sagittate, with ears at the base recurved on both sides, sometimes toothed, smooth, acuminate. Peduncles two-flowered, short, with pedicels longer than the petiole. Calyx rounded[s]. Corolla pale purple. Capsule smooth, two-celled, two-seeded.

Native of the East Indies, China and Cochinchina, where it is a common pot-herb[t].

59. This differs from *C. Batatas*, in having the leaves heart-shaped entire, three and five-lobed, not narrowed in the middle, so as to become sagittate. The roots are often as big as the fist, tubercled, fleshy like the Batatas, esculent, very soft and sapid. It flowers very seldom.—Japan, whither it was brought by the Portuguese. Far from the coast it is not known[u].]

60. This is an annual plant, rising with slender, stiff, twining stalks, eight or nine feet high. Flowers many together, at the end of strong peduncles; corolla purple.

[A plant not large. Peduncles and stem rough with yellowish hairs standing out. Leaves a little villose; the primary ones cordate-roundish, the secondary properly cordate, those next the flowers often hastate. Peduncles naked, longer than the leaves; the flowers alternate, pedicelled, with very small lanceolate involucres to each pedicel. Found in the East Indies by Osbeck[x].]

Mr. Miller says that the seeds were sent him from Jamaica by Dr. Houstoun.

[p] Hort. kew. [q] Linn. [r] Hort. kew. [s] Linn. spec. [t] Loureiro. [u] Thunberg. [x] Linn. spec.

61. Roots ſmall, white, ſtringy, ſending out ſeveral weak trailing branches. Leaves the ſize of leſſer Celandine, alternate, on long petioles. The flowers are produced on the ſide of the branches at each joint; they are of a reddiſh purple colour, appear in july, and are ſucceeded by round capſules, having three cells, with one black ſeed in each. Every part of the plant abounds with a milky juice.

[Leaves ſometimes heart-ſhaped; in open ground the ſtalks are ſhort, and lie flat ſpreading in a ſemicircular form; but among buſhes it ſometimes grows to ſome length unbranched, and does not flower[f]. Two cordate-oblong, emarginate bractes, at the baſe of the flower, incloſing the calyx, and juſt longer than it. Calyx rather five-leaved; leaflets oblong, the innermoſt involving the fruit, and each ſucceſſively wrapping round thoſe beneath it[g].

Sea coaſts of Friſia; Piedmont; Carniola. Coaſt of Norfolk, frequent. Eſſex, Kent, *&c.* North coaſt, and Scotland.—Called *Scottiſh Scurvy-graſs*, and improperly *Sea Colewort*.

Half an ounce of the juice, or a dram of the powder is an acrid purge. The leaves applied externally are ſaid to diminiſh dropſical ſwellings of the feet[a].

62. Stem ſuffruticoſe, procumbent, creeping, ſomewhat villoſe, red, long, leaves blunt at both ends, often two-lobed-pandurate, emarginate, thick, tomentoſe. Flowers axillary: corolla purpliſh[b].

Native of the Eaſt Indies, China and Cochinchina, and the eaſtern coaſt of Africa. Introduced 1770, by Monſ. Richard. It flowers in june and july, and is annual[c].]

63. Stems perennial, trailing and ſpreading to a great diſtance. Flowers large, purple, produced by threes on very long peduncles. Capſules large, oval, three-celled, with one ſeed in each cell.

Native of South America and the Weſt India iſlands, near the ſhore.

[Browne ſays that it is common near the ſea in Jamaica; that the leaves are beautifully veined; that the whole plant is very milky; and that the root is a ſtrong purgative, ſometimes uſed with ſucceſs in hydropic caſes. He calls it *purging Sea-bindweed*. Introduced before 1726, by Mark Cateſby[d].

64. Leaves ſomewhat hairy, lower cordate, upper obtuſe. Flowers in threes, parallel, ſeſſile. Involucre ſix-leaved. Corolla large.—Native of the Eaſt Indies. Annual[e].

65. Native of America.]

66. This riſes with a ſtrong winding ſtalk to the height of twenty feet, dividing into ſeveral ſmaller. The flowers are large, purple, on long peduncles; and are ſucceeded by large roundiſh ſeed-veſſels, having three cells, in each of which is lodged a ſingle ſeed. It grows naturally at La Vera Cruz in New Spain, whence the ſeeds were ſent by Dr. Houſtoun.

67. This riſes with a ſlender twining ſtalk ten feet high. The flowers are produced in ſmall cluſters on long peduncles; they are yellow, and are ſucceeded by three-cornered ſeed-veſſels, having three cells, with two ſeeds in each. It is an annual plant. The ſeeds were ſent from Carthagena in New Spain, where this plant grows naturally.

68. This alſo is an annual plant, with twining ſtalks riſing ſeven or eight feet high. The flowers come out at every joint on long ſlender peduncles, each ſupporting a large purple flower, with the calyx cut almoſt to the bottom into ten parts. It was ſent from the iſland of Barbuda.

69. Stalks ſlender twining, eight or ten feet high. Leaves ſhaped like thoſe of Convolvulus ſepium, n. 2.; but the peduncles, which are pretty long, have many purple flowers on each, growing in bunches. Capſules three-cornered, three-celled, with one ſeed in each cell. It is an annual plant, and grows naturally in Jamaica.

[This ſeems to be the ſame with C. umbellatus, n. 18. The ſame figure of Plukenet is referred to by Mr. Miller here and by Linneus there; but Sloane ſays, the flowers are yellow.]

70. This riſes with a very ſlender twining ſtalk four or five feet high. The flowers are blue. It is an annual, and the ſeeds were ſent to Mr. Miller from Jamaica, where it grows naturally.

[It may be doubted whether this be the ſame with the hederaceus of Linneus, n. 10.]

71. Stalk twining, ſeven or eight feet high. Leaves on very long petioles, and flowers on long peduncles. Seeds large, and covered with a fine down. This alſo is an annual plant, and one of the moſt beautiful ſorts, the flowers being very large, and of a fine roſe colour. It grows naturally in Jamaica, whence the ſeeds were ſent to Mr. Miller by Dr. Houſtoun.

72. Stalk ſlender, twining, five or ſix feet high. Flowers on long ſlender peduncles. Corollas white with purple bottoms. It grows naturally in Africa, whence the ſeeds were ſent to the royal garden at Paris, and thence to Mr. Miller in 1730.

[73. Native of New Zealand.

74, 75. Natives of the iſland of Tanna in the South Seas[f].

76. This is an annual, and a native of the Eaſt Indies. It flowers in july and auguſt, and was introduced 1778 by Sir Joſeph Banks, Bart.[g]

77. Stem large, ſhrubby, branched, ſcandent, ſmooth. Leaves alternate, petioled. Flowers yellow, large. Peduncles many-flowered. Corolla bell-ſhaped. Anthers filiform, ſpiral. Capſule two-celled, two-ſeeded. Native of the woods of Cochinchina.

78. Stem twining, perennial, round, extremely hairy, branched. Lobes of the leaves ovate, ſharpiſh, quite entire. Flowers white, large, axillary: common peduncle long, ſolitary; proper none. Common calyx twelve-leaved, bell-ſhaped; leaflets ovate-oblong, unequal, hairy, containing about ten ſeſſile florets. Calycine leaflets lanceolate, hairy, upright, Corolla tubular, five-cleft; ſegments acute, hairy, cloſed. Anthers bifid at the baſe. Style longer than the corolla: ſtigma capitate. Capſule two-celled, two-ſeeded. Seeds round on one ſide, angular on the other. Native of Cochinchina[h].

79. Stem twining, hairy. Leaves remote, quite entire, ſmooth on the upper, villoſe on the lower ſurface, ears rounded, having ſometimes one tooth behind: petiole only half the length of the leaf. Peduncles ſhorter than the petiole, villoſe. Calyxes hairy, with acuminate leaflets, patulous at the tip.

Native of Arabia.

Its place is between the 7th and 8th ſpecies.

80. Stem ſhrubby, erect, branched at bottom. The branches as they grow old become ſpiny, leafleſs, barren, ſubvilloſe. The flowering branches proceed from the baſe of theſe, are quite ſimple, a ſpan and more in length, erect, round, unarmed, rigid, towards the end flexuoſe and covered with a very ſoft ſhagginеſs. Leaves alternate; the lower ones lanceolate, attenuated at the baſe, ſometimes ſeveral, heaped at the exit of the branches from the ſame point, unequal: the upper ones lanceolate-linear, ſeſſile, acute: the floral ones a little broader than the reſt, all thickiſh, veinleſs, tomentoſe but not ſhining like ſilk. Peduncles almoſt from top to bottom from all the axils, ſolitary, half the length of the leaf, many-flowered. Flowers ſix to eight, ſeſſile. Involucre ſix-leaved, the length of the calyx: the three outer leaflets ovate, acute; the three inner lanceolate: all on the outer ſide, together with the peduncles and calyxes, extremely hirſute with long, very ſoft, ſhining hairs: on the inner ſide only ſomewhat hairy. Two bractes beneath each flower. Calycine ſegments linear. Corolla bell-ſhaped, hairy on the outſide, the colour of C. Cneorum. Filaments unequal: anthers linear. Style bifid, with filiform ſegments: ſtigmas acute.

It differs from C. Cneorum in the older branches becoming ſpiny, and in having axillary flowers.

[a] Woodw. mſs. [b] Loureiro. [c] Hort. kew. [d] Stokes in Withering. [e] Ibid. [f] Forſter. [g] Withering. [h] Loureiro.

Conv. ſpinoſus of the ſupplement is diſtinguiſhed from this in having the branches and leaves ſilky with minute hairs, the ſpines axillary, and the peduncles one-flowered towards the top. Conv. ſericeus of Burmann, *ind.* 49. *t.* 19. *f.* 3. probably is the ſame with this. Native of the lower Egypt and mount Sinai.

81. This is a rigid ſhrub, very much branched, diffuſed, and a foot high; the branchlets ſomewhat ſilky. Leaves ſeſſile on the branches and branchlets, ſcattered, ſilky, entire, ſmall. Flowers from the lower axils of the branchlets, commonly ſolitary, ſeldom two together. Two oblong, ſharpiſh bractes at the baſe of the calyx, a little broader at the end and reflex. Calycine leaflets hirſute, the two outer oblong, rigid, larger than the reſt. Corolla hirſute, ſmall. Stigmas two, capillary.

Native of Arabia.

The place of theſe two is between the 45th and 46th ſpecies.

82. Leaves remote, erect, oblong, cordate at the baſe with two ſmall rounded lobes on each ſide, but ſometimes entire, thickiſh, ſmooth, nerved: petiole longer than the leaf. Peduncles axillary, ſolitary or ſometimes in pairs, the length of the petioles; towards the top there is a lanceolate leaf. Calyx ſmooth, with oblong leaflets. Stigma not bifid, but capitate. Corolla and habit of Conv. Soldanella.

Native of the ſandy ſea ſhore near Naples, at Bagnoli; flowering in auguſt and ſeptember.

83. The whole plant is ſmooth. Stems filiform, purpliſh, flexuoſe. Leaves heaped, veinleſs, paler underneath: petiole longer than the leaf. Peduncles in pairs or ſolitary, axillary, equalling the petiole. Calycine leaflets equal, oblong, ſubmembranaceous. Tube of the corolla a little enlarged gradually at top. Stigma capitate.

The appearance is the ſame as in the foregoing but it is ſmoother, the leaves are ſeveral heaped together, and the ſtem decumbent, but it differs principally in its tubular corollas, but not bell-ſhaped, as in C. Imperati.

Native of the Azores iſlands.

The place of theſe two is between the 60th and 61ſt ſpecies.

84. This is wholly ſmooth, and allied to C. ſepium. Leaves acute, on a petiole the length of the leaf. Peduncle ſhorter than the petiole, thicker, bracted towards the middle, thicker under the flower. Calycine leaflets oblong, the two outmoſt ſmaller, all ſubretuſe, mucronate. Corolla of C. ſepium. Stigma capitate.

It varies with ovate leaves, having ſtraight ſhorter rounded lanceolate ears, or a little divaricate and lanceolate on the ſame plant. Conv. ſepium differs with ſubangular ears, four-cornered peduncles, and large cordate bractes at the baſe of the calyx.

Native of Spain, by the lake Albufeda in the kingdom of Valencia.

The place of this is between the 2d and 3d ſpecies.

85. Stem herbaceous, twining, pale, with plenty of ferruginous hairs ſcattered over it. Leaves on ſhort petioles, ſharp, with two-toothed ears. Peduncles axillary, ſolitary, with three ſpreading pedicels at top; both hairy. Two lanceolate bractes at the baſe of the pedicels, and two ſimilar ones on each lateral pedicel towards the flower; the middle pedicel ſhorter, without any bracte. The three outer leaflets of the calyx very hirſute, ovate, acuminate. Corolla almoſt like that of Scammony, yelloviſh, having on the outſide a lanceolate purpliſh line with a pile of yellow hairs to each lobe of the border. Style bifid. Probably native of the Levant.

86. Stem twining, herbaceous, round. Leaves rounded at the end, mucronate, gradually wider towards the baſe; the ears rounded behind. The petiole only one-fourth of the length of the leaf. Peduncle the ſame length with the leaves. One of the pedicels ſhorter and thicker, with two bractes at the baſe, the other longer with two briſtle-ſhaped bractes in the middle. Calycine leaflets ovate, acute; the outer ones more villoſe. Corolla villoſe on the outſide. Style bifid. Capſule ſmooth, globular.

Native of America.

87. Stem twining, rooting at bottom, muricated upwards with little ſpines, and having minute hairs thinly ſcattered over it at top, even. Leaves thickiſh, veinleſs, ſmooth; the lower ones an inch and half long, lanceolate-oblong, acute at the baſe; the upper ones on ſhorter petioles, an inch in length, lanceolate, rounded at the end, mucronate. The lower petioles a little ſhorter than the leaf. Peduncles ſolitary, with two minute bractes above the middle, ſomewhat villoſe at top. Calycine leaflets ſmooth, the three outer acute, mucronate, the length of the corolla, nerved; the two inner linear-lanceolate, attenuated, the ſame length with the outer ones. The corolla has five lines on the outſide, which are cloſely beſet with fulvous, ſhining hairs. Stigma capitate. Capſule ſmooth, ſhorter than the calyx.

Native of the Eaſt Indies, where it was obſerved by Koenig.

The proper place of theſe three is between the 5th and 6th ſpecies.

88. Stem herbaceous, filiform, twining, branched. Leaves on very ſhort petioles, diſtant, two inches and more in length, quite entire except at the baſe, veined, tender, very ſmooth, a little narrowed both ways; the ears having three or four mucronate teeth on each ſide. Peduncles axillary, filiform, one-flowered, thickened at top. Bractes in pairs, oppoſite, ſubulate, above the middle of the peduncle. Calycine leaflets oblong, mucronate, ſmooth. Stigma ſimple, bluntiſh.—It is nearly allied to Evolvulus tridentatus.

Native of Guinea, and found there by Iſert.

89. Stem filiform, twining, ſmooth, branched. Leaves petioled, an inch or rather more in length; ears lanceolate, acute, ſometimes ſtraight, ſometimes a little reflex, uſually quite entire, but having, though very ſeldom, an obſcure toothlet behind. Peduncles filiform, a little longer than the leaf, having two ſhort briſtle-ſhaped bractes in the middle. Leaflets of the calyx equal, oblong, ſmooth. Corolla bell-ſhaped, ſmooth. Stigma bifid.—Native of the Eaſt Indies.

It differs from C. japonicus in having a branched ſtem, blunt leaves, with the ſide-lobes ſcarcely a quarter of an inch in length, and the calycine leaflets rounded at the end and mucronate, not acute.

The proper place of this and the foregoing ſort is between the 6th and 7th ſpecies.

90. Stem twining, round, ſmooth. Leaves ſcarcely an inch long, ſubcordate at the baſe; the middle lobe lanceolate and quite entire, the ſide ones roundiſh, unequally four or five-toothed: petioles filiform, ſhorter than the leaf, often ſubmuricate towards the baſe. General peduncles ſpreading, thicker and a little longer than the petiole; partial peduncles in threes, the middle one-flowered, the ſide ones with two or three pedicelled flowers: both muricate, rigid. Calycine leaflets oblong, obtuſe, mucronate, equal.

Native of the Eaſt Indies: found by Schumacher.

Its proper place is between the 7th and 8th ſpecies.

91. Stem herbaceous, twining, with ſhort hairs thinly ſcattered over it. Leaves two inches long, ſmooth, veined underneath; the middle lobe lanceolate, attenuated, quite entire, mucronate, the ſide ones broader, rounded upwards, entire, or retuſe-ſublobate outwards, the lobes roundiſh: petioles ſhorter than the leaf, pubeſcent. Peduncles the length of the leaf, ſolitary. Two oppoſite, lanceolate, acute bractes a little below the calyx. Calyx pubeſcent, the two outer leaflets much broader than the inner ones, oblong, bluntiſh, nerved, pubeſcent: the latter incloſed by the former as between two bractes, lanceolate and a little ſhorter. Corolla villoſe on the outſide, tender, ſilky, with a five-cleft border. Stigma capitate, two-lobed.—The form of

the leaves is nearly the ſame as in C. platanifolius, but the ears are not toothed only retuſe on the ſides, the peduncles are one-flowered, not two or three-flowered; but it differs chiefly in having the two outer leaflets of the calyx broad.

Found in the Eaſt Indies by Koenig.

92. Corolla white with a violet purple baſe, hairy on the outſide. The bractes, calyx, and corolla as in the foregoing ſpecies; from which however it differs in having a villoſe ſtem; leaves cordate at the baſe, acute, mucronate, not attenuated, nearly equal in length and breadth, one, two or three-lobed at bottom, villoſe on both ſides, very ſoftly villoſe, hoary and obſcurely veined underneath, the younger ones ſilky; and the peduncles longer.

Found in the Eaſt Indies, by Schumacher.

93. The whole plant quite ſmooth, except the petioles. Stem round. Leaves two inches long and more, glaucous-green underneath, with purpliſh veins; lobes lanceolate, the middle one longer, broader, quite entire, acuminate; the ſide ones narrower, attenuated, with a ſmaller, broader lobe at bottom without on each ſide, having an angular tooth, and being rounded behind. Petioles ſhorter than the leaf, beſet with a few ſcattered hairs. Peduncles ſolitary, ſhorter than the leaf; the lower three-flowered, the middle two-flowered, the uppermoſt one-flowered, thickened at top. Calycine leaflets oblong, ſubmembranaceous, ending in a briſtle. Stigma capitate. It differs altogether from Conv. Batatas in the ſmoothneſs of the ſtem, and the form of the leaves.

Native of America.

94. Stem twining, with a few minute hairs ſcattered over it, preſſed cloſe to it, and viſible only with a magnifier. Leaves four inches long, three inches or more wide at the baſe, three-lobed or entire, very ſmooth, nerved, a little paler underneath, ſharp, quite entire, the ſide-lobes lanceolate, the middle one ovate, attenuated: petioles longer than the leaf. Peduncles axillary, the length of the petioles. Flowers about five, alternate: pedicels an inch and half long, a little thicker under the leaf. At the baſe of each pedicel a lanceolate attenuated bracte, very finely nerved and ſmooth. Calycine leaflets lanceolate, attenuated, tender, very finely nerved, quite ſmooth, the two inner ones a little ſhorter. Corolla large, bell-ſhaped, purple with a pale baſe, with five paler, lanceolate, attenuated rays, running to the edge. Stigma capitate.

Native of the iſland of Santa Cruz, in the Weſt Indies.

The four laſt have their place between the 7th and 8th ſpecies.

95. Stem twining, tender, pubeſcent at top. Leaves an inch long, obſcurely ſeven-nerved, a little acuminate, blunt with a ſmall point, the upper ſurface thinly villoſe when viewed with a magnifier, paler and more villoſe underneath: petioles the length of the leaves. Peduncles the length of the petiole, thickened at top, two-flowered, ſeldom one-flowered: pedicels a little ſhorter than the peduncle; one ſhorter, thicker, without any bracte, the other more tender, with two bractes in the middle, both turned back when ripe. Calycine leaflets oblong, obtuſe, ſcarcely appearing hairy with a magnifier; when fruit-bearing ſmooth. Corolla bell-ſhaped, ſix times as large as the calyx, ſmooth. Stigma capitate.

Native of the iſland of Java.

96. Stem herbaceous, twining, pubeſcent, round, ſlender. Leaves two inches long, remote, quite entire, with a rounded mucronate point, ſmooth on both ſides except the rib, ſimply veined: petioles the length of the leaves, pubeſcent. Peduncles ſolitary, pubeſcent: pedicels in threes, the ſide ones jointed, one of them often two-flowered; the middle one ſhorter, a little thicker, without any bracte. On the lateral pedicels at the joint are two bractes which are oblong, concave, ſmall, villoſe, deciduous. Calycine leaflets oblong, obtuſe, equal, concave; the two outer villoſe and ſomewhat hoary. Corolla bell-ſhaped, twice as long as the calyx, white with a duſky purple baſe, with five lanceolate paler rays above running to the edge with five deeper coloured ſtreaks. Stigmas capitate, two-lobed.

Found by Koenig in the Eaſt Indies.

97. Stem twining; branched round, purpliſh, villoſe, rugged. Leaves two inches long and more, quite entire, veinleſs, nerved, on the upper ſurface appearing ſubvilloſe to a magnifier, on the under very ſoft with a cloſe pile; petiole only half the length of the leaf. Peduncles axillary, a ſhort ſpan in length, round, villoſe, rugged, floriferous at top. Pedicels very ſhort, branched, faſtigiate. At the baſe of the head of flowers is a lanceolate leaf on each ſide. Bractes linear, the length of the calyx. Calycine leaflets linear-lanceolate, hairy-tomentoſe, as are alſo the bractes. Lobes of the corolla acuminate. Stigmas two, reflex.

Native of Cayenne.

98. The whole of this plant is hiſpid, eſpecially the branches towards the top, the involucres and calyxes; the hairs are long, diſtinct, placed on minute dots, of a dirty white colour. Stem twining, herbaceous, rugged. Leaves from two to three inches long, acute, ciliate, paler underneath, obſcurely nerved: petiole a little ſhorter than the leaf. Peduncles axillary, ſolitary, a little ſhorter than the leaves, without any joint. Flowers five ſeſſile, collected into a head. Involucres five-leaved; leaflets the length of the calyx, oblong, acute, ſmooth within. Calycine leaflets ovate-lanceolate, acuminate, ſmooth within, one-third only of the length of the corolla; which is hiſpid on the outſide with long hairs arranged in five lines. Stigma capitate, Capſule ſubglobular, ſhorter than the calyx, with a very even ſurface and ſmooth.

It differs from Ipomæa tamnifolia of Linneus in its large corollas hiſpid on the outſide, not minute and ſmooth as in that, and in the calycine leaflets being ovate not linear-lanceolate: it alſo comes from a different country. I. tamnifolia of Burm. ind. may perhaps be the ſame with this ſpecies of Convolvulus.

Native of the Eaſt Indies. Found by Koenig.

99. The whole of this plant is rough with hairs. Stem twining. Leaves from two to three inches long, attenuated, quite entire, a little paler underneath. Petiole only half the length of the leaf. Pedicels umbelled, the length of the peduncle. Calycine leaflets lanceolate, attenuated, ſmooth within, lax. Corolla ſmooth. Stigma capitate. It is eaſily known from the other ſpecies with entire leaves by its ſhagginеſs.

Native of the Eaſt Indies: obſerved by Dahl.

100. Stem weak, ſlightly villoſe at top. Leaves an inch long: petiole the length of the leaf, villoſe, filiform. Peduncles the length of the leaves, filiform: pedicels umbelled; the lateral ones ſomewhat branched. Calycine leaflets ovate, acuminate, ſmall. Corolla blue, ſmooth, twice as long as the calyx, five-cleft. Stigma bifid, with the ſegments revolute.

Native of Java.

The proper place of the ſix laſt plants is between the 15th and 16th ſpecies.

101. The ſtem, together with the petioles, peduncles and calyxes villoſe. Leaves an inch long, a little acuminate. Peduncles three or four times longer than the leaf, bifid: partial peduncles three or five-flowered. Bractes linear-lanceolate at the baſe of the partial peduncles. Calycine leaflets tender, the two outer cordate, one lanceolate, the two inner ſubmembranaceous, ſmooth, only half the ſize, mucronate. Corolla bell-ſhaped, violet with five lanceolate paler rays. Stigmas two reflex.—It varies with ſmoother and hairy leaves.

Native of the iſland of Santa Cruz.

This comes in between the 16th and 17th ſpecies.

102. Stem herbaceous, twining, ſmooth. Leaves two inches long, quite entire, ſimply veined, the veins underneath villoſe when examined with a magnifier; the under ſurface is paler; they are rounded at the end and mucronate; the lobes are rounded

rounded behind, and are ſometimes, but ſeldom, obſcurely angular. The petiole is ſhort. Peduncles ſhorter than the leaf: pedicels angular, without bractes, thickened towards the top, equal, almoſt the length of the peduncle. Calycine leaflets blunt. Corolla three times as long as the calyx; lobes hairy at the tip. Stigma capitate.

Native of the Eaſt Indies: obſerved by Koenig.

103. Stem twining, villoſe. Leaves from two to three inches long, an inch or rather more wide at the baſe, mucronate, frequently ſomewhat villoſe on the upper ſurface, hoary and very ſoft on the under. Petiole one-third of the length of the leaf, hoary. Peduncles axillary, ſolitary. Pedicels very many, ſubumbelled; with minute ſcales at the baſe inſtead of bractes; they are oblong, ferruginous and deciduous. Calycine leaflets pubeſcent at the baſe, rounded at the tip, equal. Corolla almoſt funnel-ſhaped, three times as long as the calyx, with five ſlender villoſe lines on the outſide: lobes acute, bearded at the tip. Stigma capitate, two-lobed. Capſule ovate, ſtriated, ſmooth.—It has the habit of Conv. umbellatus, but has ſmaller, narrower leaves. The variety differs ſcarcely in any thing elſe but in its ſmoothneſs, and the leaves being ſtill narrower.

Native of the Eaſt Indies, and the iſland of Java.

Its place is between the 17th and 18th ſpecies.

104. Stem pubeſcent, rendered triangular by three ſubfoliaceous very ſlender decurrent lines. Leaves two inches long and more, each ſurface has hairs ſcattered over them, which are preſſed cloſe, on the upper ſurface they are not to be ſeen without a magnifier, but on the lower they are more apparent. Petiole villoſe, ſhorter than the leaf. Peduncle the length of the leaves, three or five-flowered: lateral pedicels two-flowered, the middle one one-flowered, ſhorter; they gradually thicken towards the top. Bractes at the baſe of the pedicels, ovate, concave, tender, acute, mucronate, coloured, deciduous, pubeſcent. The two outer calycine leaflets bracte-ſhaped, ovate, acute, mucronate, ſilky: the inner ones ſmooth, ſhorter, rounded at the tip. Stigma capitate.—This is very nearly allied to Conv. anceps, but the leaves are not blunt, and the wings on the ſtem are only one-third of the width.

Native of the iſland of Santa Cruz.

Its proper place is between the 20th and 21ſt ſpecies.

105. Stem ſlightly pubeſcent, round, branched. Leaves tender, hoary; the lower an inch and half long, broader, ſagittate-ovate, crenate-ſubrepand; the upper two inches long, narrower, more attenuated, obſcurely crenate; ears ſtraight, ſubtruncate behind, one-toothed. Petiole ſhorter than the leaf. Peduncles the length of the leaves, pubeſcent, moſt of them five-flowered, but the uppermoſt three-flowered: pedicels in threes, umbelled, the lateral ones on the lower peduncles bifid. There are two linear bractes at bottom on the lateral pedicels, but there is none on the middle one. Calycine leaflets oblong, blunt, mucronate, ſomewhat villoſe. Corolla twice as long as the calyx, with the lobes bearded at the tip. Stigma bifid.—Suppoſed to be a native of the iſle of Bourbon.

106. Stem twining. Leaves nerved, mucronate; ears ſtraight, oblong, obtuſe. Petiole one-third of the length of the leaf. Peduncles ſolitary, the length of the leaves, having a pair of briſtle-ſhaped bractes towards the tip. Calycine leaflets oblong, ſharpiſh, almoſt equal; the two inner ones ſmooth. Corolla half as long again as the calyx, marked on the outſide with five lanceolate, villoſe, ſilky lines; the lobes bearded at the tip. Stigma ſlightly bifid.—Suppoſed to be a native of Braſil. Both theſe were collected by Monſ. Thouin; and their place is between the 30th and 31ſt ſpecies.

107. Stem round, twining. Leaves five-lobed; lobes oblong, the middle one ſcarcely an inch in length, the lateral ones gradually ſmaller and narrower, ſmooth, nerved, very finely veined, mucronate, appearing very neatly ſerrulate when viewed with a glaſs. Petioles filiform, an inch long. In the axils are two ſmall petioled leaves, of the ſame ſtructure with thoſe on the ſtem, almoſt as in Conv. cairicus. Peduncles the length of the petioles, filiform, a little thickened at top, without any bractes. Calycine leaflets oblong, obtuſe, ſmooth. Corolla almoſt bell-ſhaped, ſmooth, purple. Stigma capitate, two-lobed. It is allied to C. cairicus, but has ſmaller five-cleft leaves with blunt lobes, and one-flowered peduncles.

Native of the iſland of Santa Cruz.

Its place is after the 32d ſpecies.

108. Stem twining, round, ſmooth. Leaves petioled, digitate: leaflets five, the middle one ſub-ovate, two inches long or a little more, the lateral ones gradually ſmaller and narrower, all ending in a long point, ſharp at the baſe, quite ſmooth on both ſides, veined. Peduncles longer than the leaf, round, ſmooth. Peduncles umbelled, the lateral ones divided, a little thicker below the flower; at their baſe an ovate-cordate, acuminate, ſolitary leaf. Calyx ſmooth; the leaflets ovate, membranaceous at the edge, two large. Corolla funnel-ſhaped. Stigma capitate, ſlightly two-lobed —It approaches to Conv. glaber of Aublet (Guian. t. 53.), but ſeems to differ in having the leaves acuminate but not attenuated, with more and ſhorter pedicels, and the tube of the corolla nearly of the ſame diameter throughout, not gradually enlarged towards the top.

Its country is unknown. Its place is between the 39th and 40th ſpecies.

109. The whole of this plant is ſmooth. Stem angular, twining. Leaves petioled: leaflets five or ſix, very narrow, quite entire. Peduncles axillary, ſhort, uſually four or five-flowered, the upper ones ſometimes one-flowered. Calyx ſmooth, with oblong leaflets. Stigma acute.

Native of the Weſt Indies.

Its place is after the 40th ſpecies.

110. This differs from Conv. Cneorum, which it otherwiſe reſembles, in being wholly covered with a lanuginous ſhagginеſs, inſtead of ſilvery-ſhining appreſſed ſcarcely diſtinct hairs, as that is; in having linear remote leaves, not widening towards the outſide, linear-ſubulate calycine leaflets, and ſubſeſſile flowers. The corolla and ſtigma as in C. Cneorum.

Native of Spain.

Its place is after the 46th ſpecies[1].]

PROPAGATION AND CULTURE.

1, 2. Theſe are troubleſome weeds in gardens, and ſhould be rooted out with great care. Every ſmall piece of the root will grow, and therefore it is difficult to deſtroy them. With reſpect to the ſecond ſpecies, Mr. Miller obſerves, that being generally among trees and ſhrubs, or under hedges, the roots are ſo intermixed, that it cannot eaſily be extirpated; but in an open clear ſpot of ground, where the plants are carefully hoed down for three or four months, they may effectually be deſtroyed; for when the ſtalks are broken or cut, a milky juice flows out, and the roots are ſoon exhauſted and decay.

[On the contrary Mr. Curtis remarks of the firſt ſpecies, which is the weed that infeſts arable lands, that the more he cut and hoed it, the more it ſpread and the faſter it grew. In effect, it cannot be eradicated, without repeated ploughing in dry weather, and then picking out the roots and burning them.]

3. Scammony is a hardy plant, and will thrive very well in the open air in England, on a dry ſoil.

Sow the ſeeds in the ſpring on a border of light earth; keep the plants clean from weeds, and thin them to the diſtance of three feet. The ſtalks decay in autumn, but the roots will abide many years.

12. Purple Bindweed, commonly called by gardeners *Convolvulus major* is propagated by ſowing the ſeeds in the ſpring, upon a warm border, where the plants are deſigned to remain. Some tall ſtakes muſt be placed by them, for the ſtalks to twine

[1] Vahl.

hour, otherwiſe they will ſpread on the ground, and make a bad appearance.

12. β. 11. The more tender varieties and the eleventh ſort muſt be brought forward on a hot-bed, and planted out on a warm border towards the end of may.

15. Spaniſh Potatoe is cultivated in warm climates by the roots, in the ſame manner as our common Potatoe, but requires much more room, for the trailing ſtalks extend four or five feet every way, ſending out large tubers, forty or fifty of which are produced from a ſingle root. In England, the roots muſt be planted on a hot-bed in the ſpring, and if the plants are kept covered in bad weather with glaſſes, they will produce flowers, and many ſmall roots from the joints; but if they are expoſed to the open air, they ſeldom make much progreſs.

20. Canary Bindweed ſometimes ripens ſeeds here, but being eaſily propagated by layers or cuttings, the ſeeds are not much regarded. Thoſe plants, however, which are raiſed from layers or cuttings, do not produce ſeed, whereas thoſe which come from ſeeds ſeldom fail.

If the young ſhoots are laid down in the ſpring, they generally put out roots in three or four months; then they be taken from the old plant, and each put into a ſeparate pot filled with light earth, and placed in the ſhade till they have taken new root; after which they may be placed with other hardy green-houſe plants till autumn, when they muſt be removed into the green-houſe, and treated as Myrtles, &c. The tender cuttings planted during any of the ſummer months in pots filled with light earth, plunged into a moderate hot-bed, and ſhaded from the ſun, will take root, and may be treated as the layers.

The leaves continuing green all the year, this plant makes a pretty variety during the winter in the green-houſe.

6, 10, 13, 14, 17, 18, 19, 21—26, 28, 30, 31, 35—41, 57, 58, 60, 62—71, 76—81, & 85—109. Being natives of warm climates, chiefly of the Eaſt and Weſt-Indies, are tender. When raiſed from ſeeds, they muſt be ſown on a hot-bed in the ſpring, and when the plants are fit to remove, they muſt be tranſplanted each into a ſeparate pot filled with light earth, and plunged into a moderate hot-bed, obſerving to ſhade them from the ſun till they have taken new root; then they ſhould have a large ſhare of air admitted to them every day, to prevent their drawing weak, and alſo moderate waterings every other day. When the plants are become too tall for the hot-bed, they muſt be ſhifted into larger pots, and placed in the bark-ſtove, where if they are allowed room they will flower; but they rarely produce ſeeds in England. Many of them therefore are continued by cuttings.

29. C. Jalapa, the root of which is the true Jalap, being a native of South America, muſt be preſerved in the bark-ſtove. It may be raiſed from ſeeds on a hot-bed, the young plants being removed into pots muſt be plunged into the bark-bed, and treated in the ſame manner as the laſt mentioned ſet of plants, with this difference only, that as this has large, fleſhy, ſucculent roots, it muſt have but little water, eſpecially in winter. The proper ſoil for the Jalap is a light ſandy loam, not too rich, and the plants ſhould always remain in the bark-ſtove. [It may be alſo increaſed from ſlips or cuttings.]

32. Mallow-leaved Bindweed, and the variety ſeldom produce ſeeds in England, but creeping at the root are propagated by off-ſets or ſhoots taken from the old plants. The beſt time for parting and tranſplanting this ſort is about the beginning of may, when it may be taken out of the green-houſe, and expoſed to the open air; but the young plants ſhould be placed under a frame, and ſhaded from the ſun till they have taken new root: they may then be gradually hardened to the open air during the ſummer; but in autumn they muſt be placed in the green-houſe, and treated in the ſame way as Canary Bindweed, n. 20.

44. If the ſeeds of Sicilian or ſmall-flowered Bindweed are permitted to ſcatter, the plants will riſe in the ſpring, and require no other culture but to keep them clean from weeds: or if the ſeeds are ſown in the ſpring where the plants are to remain, they will flower in june, and the ſeeds will ripen in auguſt.

46. Dwarf Bindweed ſeldom produces ſeeds in England, but the roots propagate in plenty. It prefers a light dry ſoil, and requires no other care but to keep the plants clean from weeds: it may be tranſplanted either in ſpring or autumn.

47. Cneorum or ſilvery-leaved Bindweed will live in the open air in mild winters, if planted in a light ſoil and a warm ſituation, but in ſevere winters it is deſtroyed; ſome of the plants therefore ſhould be kept in pots, and ſheltered under a common frame in winter, where they may enjoy the free air in mild weather, and yet be protected from froſt: in ſummer they may be placed abroad with other hardy exotic plants, where the fine ſilky leaves will make a pretty appearance. This ſort may be propagated by laying down the branches, and alſo by cuttings; but both very ſeldom put out roots the ſame year, and many of them will fail, ſo that the beſt way is to procure ſeeds from Italy; and thoſe plants which come from ſeeds grow much larger than thoſe which are propagated the other ways.

48. Cantabrica or flax-leaved Bindweed is propagated by ſeeds, which muſt be obtained from the countries where it naturally grows; theſe ſhould be ſown upon a warm dry border, where they are deſigned to remain; for as the plants run down with long tap-roots, they will not bear tranſplanting, for I have often made trial of this without any ſucceſs. When the plants come up, they ſhould be thinned where they grow too cloſe, and afterward conſtantly kept clean from weeds, which is all the culture it will require. It flowers in july and auguſt, and the ſtalks decay in autumn; but the roots will laſt ſeveral years, and if they are in a dry ſoil and warm ſituation, will abide through the winter very well without covering.

50. Broom Bindweed may be increaſed and treated in the ſame manner. It muſt have a dry ſoil and warm ſituation to enable it to live through the winter in the open air in England. If the ſurface of the ground about the roots be covered with ſome old tanner's bark, it will preſerve them in the hardeſt froſts.

56. Convolvulus tricolor or trailing Bindweed has been long cultivated as an ornamental plant in the borders of our flower-gardens, under the name of *Convolvulus minor*. It is an annual plant, and is propagated by ſeeds, which ſhould be ſown on the borders of the flower-garden where they are deſigned to remain. The uſual method is to put two or three ſeeds in each place where they are intended to flower, covering them half an inch with earth; and when the plants come up, if the ſeeds all grow, there ſhould be but two left in each place, which will be ſufficient; the others ſhould be drawn out carefully, ſo as not to diſturb the roots of thoſe which are left; after which they will require no other culture but to keep them clean from weeds. If the ſeeds are ſown in autumn, the plants will flower in may; but thoſe which are ſown in the ſpring, will not flower till about the middle of june, and will continue flowering till the froſt ſtops them. The ſeeds ripen in auguſt and ſeptember.

The plants which bear variegated flowers have frequently plain flowers of both colours intermixed with them: theſe ſhould be pulled off as ſoon as they appear, in order to continue the variegated or ſtriped flowers.

61. Soldanella or Sea Bindweed growing naturally on the ſea beach, cannot be long preſerved in a garden.

[Of theſe numerous ſpecies of Convolvulus, the following only will bear the open air, viz. 1, 2, 3, 4, 8, 9, 12, 44, 45, 46, 47, 48, 56 and 61.

Theſe require the protection of a green-houſe: viz. 5, 8, 20, 32, 33, 47, 48, 50, 52: ſome always, and others in ſevere winters only; as 8, 47 and 48.

The reſt, which have been hitherto introduced into culture, will not live in England through the winter, unleſs they are kept in a ſtove: as 6, 11, 14, 15, 18, 21, 23, 26, 29, 37, 41, 62, &c.

CONVOLVULUS. See *Evolvulus, Ipomæa, Pæderia* and *Polygonum*.

Convolvulus braſilianus. See *Ciſſampelos*.

——— nummularius, &c. See *Evolvulus*.]

CONŸZA. (*Either from κώνωψ a gnat, becauſe it catches ſmall inſects by its glutinous juice—or παρὰ τὸ κονίζειν, from its being covered by a duſty pubeſcence—or παρὰ τὸ τὸν κυνὰ ὀζειν, from ſmelling like a dog. Ray.—From κνύζα ſcabies, the itch. Vaill.*)

Lin. gen. n. 950. *Reich.* 1030. *Schreb.* 1286. *Gærtn. t.* 166. *Juſſ.* 180.

Claſſ. 19. 2. Syngeneſia Polygamia Superflua.

Nat. order of *Compoſitæ Diſcoideæ. Corymbiferæ* Juſſ.

GENERIC CHARACTER.

CAL. *Common* imbricate, roundiſh, ſquarroſe: *ſcales* acute, the outer ſomewhat ſpreading.

COR. *Compound* tubuloſe; *Corollets* hermaphrodite numerous, tubular in the diſk. *Females* apetalous, roundiſh in the circuit. *Proper*, of the hermaphrodite funnel-form; *border* five-cleft, patulous.

Of the *Females* funnel-form; *border* three-cleft.

STAM. In the Hermaphrodites *filaments* five, capillary, very ſhort. *Anther* cylindric, tubular.

PIST. In the Hermaphrodites, *Germ* oblong. *Style* filiform, length of the ſtamens. *Stigma* two-cleft.

In the Females, *Germ* oblong; *Style* filiform, length of the hermaphrodite, more ſlender. *Stigmas* two, very ſlender.

PER. none, Calyx converging.

SEEDS to the hermaphrodites ſolitary, oblong, *down* ſimple. To the females ſolitary, oblong; *down* ſimple.

REC. naked, flat.

ESSENTIAL CHARACTER.

Cal. imbricate, roundiſh. *Cor.* of the ray three-cleft. *Down* ſimple. *Recept.* naked.

SPECIES.

1. Conyza ſquarroſa. *Great Fleabane*, or *Plowman's Spikenard.*

Lin. ſpec. 1208. *Reich.* 3. 776. *Lour. cochinch.* 496. *Burm. ind.* 179.
Senecio amboinicus. *Rumph. amb.* 6. 36. *t.* 14. *f.* 2.
Leaves lanceolate-ovate reflex-ſerrate tomentoſe underneath; flowers terminating heaped.]

19. Conyza hirſuta. *Shaggy Fleabane.*
Lin. ſpec. 1209. *Reich.* 3. 776. *Burm. ind.* 180. *Lour. cochinch.* 496.
Leaves oval quite entire ſcabrous, hirſute underneath.

20. Conyza arboreſcens. *Tree Fleabane.*
Lin. ſpec. 1209. *Reich.* 3. 776. *Swartz. obſ.* 304. *Plum. ſpec.* 10. *ic. t.* 130. *f.* 2. *Sloan. jam.* 1. 257. 11. *Brown. jam.* 313. *n.* 1. (*Eupatorium.*)
Leaves ovate quite entire acute tomentoſe underneath; ſpikes recurved one-ranked; bractes reflex.

[21. Conyza fruticoſa. *Shrubby Fleabane.*
Lin. ſpec. 1209. *Reich.* 3. 776.
Eupatorium amer. frut., hederæ terreſtris fol., flore purpuraſcente. *Plum. ſpec.* 10.
Leaves ovate quite entire obtuſe; flowers ſeſſile alternate; branchlets flexuoſe.

22. Conyza virgata. *Winged-ſtalked Fleabane.*
Lin. ſpec. 1206. *Reich.* 3. 777. *Plum. ſpec.* 9. *ic.* 98. *f.* 1. *Brown. jam.* 318. *n.* 2.
Guaphalium virgatum. *Lin. amæn.* 5. 405.
Leaves decurrent lanceolate ſerrulate; ſtems wand-like; flowers ſpiked, in ſcattered heaps.

23. Conyza decurrens.
Lin. ſpec. 1206. *Reich.* 3. 777.
Leaves decurrent lanceolate ſerrulate; flowers axillary ſeſſile glomerate.

24. Conyza aurita.
Lin. ſyſt. 753. *ſuppl.* 367.
Leaves dentate-ſimate; earlets ſubdecurrent.

Species from Hortus Kewenſis.

25. Conyza Inuloides. *Cluſter-flowered Fleabane.*
Ait. hort. kew. 3. 182.
Chryſocoma dichotoma. *Lin. ſuppl.* 359. *Jacq. ic. collect.* 1. 44.
Leaves cuneiform-linear obtuſe notch-toothletted ſmooth; ſtem ſhrubby; anthers two-briſtled.

26. Conyza ſericea. *Snowy Fleabane.*
Ait. hort. kew. 3. 183.
Chryſocoma ſericea. *Lin. ſuppl.* 360.
Leaves linear-filiform, thry and the ſtems tomentoſe-ſilky; flowers panicled.

27. Conyza ægyptiaca. *Egyptian Fleabane.*
Ait. hort. kew. 3. 183.
Erigeron ægyptiacum. *Lin. mant.* 112. *Jacqu. hort.* 3. 14. *t.* 19.—ferratum. *Forſk. deſcr.* 148.
Leaves oblong-ſpatulate toothed hairy, flowers ſubpanicled globular; calytine leaflets ſubulate ſoft.

28. Conyza rugoſa. *St. Helena Fleabane.*
Ait. hort. kew. 3. 184.
Shrubby; leaves wedge-ſhaped ſerrate villoſe wrinkled netted; peduncles villoſe one-flowered; flowers radiate.

29. Conyza inciſa. *Ear-leaved Fleabane.*
Ait. hort. kew. 3. 184.
Leaves ovate ſubcordate hairy-vifcid toothed, eared at the baſe; axiſk of the receptacle honey-combed.

30. Conyza patula. *Spreading Fleabane.*
Ait. hort. kew. 3. 184.
Serratula. *Mill. fig.* 165. *t.* 247. *dict. edit.* 7. *n.* 9.
Leaves elliptic ſerrate villoſe underneath; calyxes ſubglobular, leaflets lanceolate-ſubulate; branches ſpreading.]
Species from South America, in Miller's Dictionary.

31. Conyza tomentoſa.
Mill. dict. n. 5. *Houſt. Mſs.*
Arboreſcent; leaves oblong-ovate tomentoſe cinereous underneath; flowers terminating, on branching peduncles.

32. Conyza ſalicifolia. *Willow-leaved Fleabane.*
Mill. dict. n. 6. *Houſt. Mſs.*
Leaves linear decurrent ſerrate; flowers corymbed terminating.

33. Conyza corymboſa.
Mill. dict. n. 7. *Houſt. Mſs.*
Arboreſcent; leaves lanceolate, flowers corymbed terminating, on branching peduncles.

34. Conyza viſcoſa.
Mill. dict. n. 8. *Houſt. Mſs.*
Herbaceous; leaves ovate ſerrate villoſe; flowers both axillary and terminating.

35. Conyza ſymphytifolia. *Comfrey-leaved Fleabane.*
Mill. dict. n. 10. *Houſt. Mſs.*
Leaves oblong-ovate ſcabrous; flowers racemed terminating; ſtem herbaceous.

36. Conyza ſcandens. *Climbing Fleabane.*
Mill. dict. n. 11. *Houſt. Mſs.*
Leaves lanceolate ſcabrous nerved ſeſſile; racemes recurved; flowers aſcending, peduncles lateral; ſtem ſhrubby climbing.

37. Conyza trinervia.
Mill. dict. n. 12. *Houſt. Mſs.*
Leaves ovate ſmooth three-nerved quite entire ſeſſile; flowers in ſpikes terminating; ſtem ſhrubby.

38. Conyza uniflora.
Mill. dict. n. 13. *Houſt. Mſs.*
Leaves lanceolate acute ſeſſile; flowers ſolitary lateral; calyxes coloured; ſtem ſhrubby branching.

39. Conyza ſpicata.
Mill. dict. n. 14.
Shrubby; leaves ovate three-nerved; flowers in axillary ſpikes.

40. Conyza pedunculata.
Mill. dict. n. 15.
Leaves ovate-lanceolate three-nerved; peduncles very long terminating; flowers in corymbs.

41. Conyza Baccharis.
Mill. dict. n. 16.
Leaves ovate-oblong obtuſe ſerrate half-ſtem-claſping; flowers in terminating corymbs.

From Swartz.

42. Conyza purpuraſcens.
Swartz prodr. 112. *Brown. jam.* 318. 1. *Sloan. jam.* 1. 258. *t.* 152. *f.* 1. *Mill. dict. n.* 17. (odorata.)
Leaves ovate-lanceolate ſerrate ſubtomentoſe, ſtem ſubherbaceous ſimple at bottom corymbed at top, flowers ovate.

[43. Conyza rigida.
Swartz prodr. 113. *Plum. ic.* 14. *f.* 1.
Leaves petioled obovate entire rugged, veined underneath, ſpikes flexuoſe, flowers in pairs, all directed the ſame way.

DESCRIPTIONS, *&c.*

The Conyzas are either herbaceous or ſhrubby; in a few of them the leaves are decurrent; the flowers are of the compound kind without any ray, in corymbs or panicles at the top of the ſtem and branches*. The genus Baccharis is ſcarcely diſtinct from this, in the opinion of Juſſieu, Lamarck, Gærtner, &c..

1. Root biennial. Stems a foot in height, upright, panicled at the end, purpliſh with a white woollineſs. Branches ſtraight. Leaves ovate-oblong, terminating in petioles, wrinkled, ſerrate,

* Juſſieu.

ſpreading, bowed back. Flowers terminating, ſtraight.

Stem from two to three feet high and more, firm, ſomewhat angular, ſtriated, downy, branched towards the ſummit: (according to Withering, nearly cylindric, reddiſh, rough, with ſhort woolly hairs.) Lower *leaves* large; upper decreaſing, bluntly oval-lanceolate, petiolate, irregularly ſerrate, downy on both ſurfaces: (or woolly underneath, and hairy above): thoſe at the baſe of the flowering branches lanceolate, or linear lanceolate; ſcarce perceptibly ſerrate. Numerous flowering heads terminate the ſtem and branches, on ſhort downy peduncles; with each a ſmall lanceolate bracte. *Calyx* imbricated with numerous ſcales; the lower green, ſomewhat ſpreading; the upper yelloviſh, with green ſpreading tips; all linear-lanceolate: (according to Withering, ſcales purpliſh at the edge, with very ſhort woolly hairs on the outſide. *Corollas* yellow, yelloviſh, or duſky purple; florets without piſtils, in the circumference with piſtils; individuals with only piſtils ſlightly cloven into three, have at firſt ſight the appearance of a funnel-ſhaped floret; but are really more of the nature of a ligulate floret.) *Seeds* ſmall, blackiſh, longitudinally furrowed, crowned with a ſeſſile feather, with ſimple rays as long as the calyx [b].

The ſmell is ſlightly, but not ungratefully aromatic. Tragus reports it to be an emmenagogue, but it is ſcarcely known officinally [c].

Native of Denmark, Great Britain, Germany, Holland, France, Switzerland, Carniola, Piedmont: chiefly on dry mountainous paſtures; by hedge ſides and in woods: with us moſtly in a calcareous ſoil; as in Cambridgeſhire, at Shelford, Whittleſford, Hilderſham and Abington:—common alſo in woods in Norfolk, in a clayey ſoil. Charlton wood, and near Dartford and Greenhithe, in Kent. Near Hareſield, in Middleſex. Finſhead, in Northampton. Scotland, but not common. It flowers from july to october.

2. Stems a foot or a foot and half in height, erect, hardiſh, green. Leaves reſembling thoſe of *Mezereon* or *Hyſſop*, only more obtuſe, ſmooth and ſtiff. Branches ſlender, ſtraight at the top of the ſtems. Flowers on ſhort peduncles, terminating: florets white, ſlender, reflex. Cultivated (1699) in Chelſea garden [d].

It flowers in auguſt and ſeptember.

3. Allied very nearly to *C. ſaxatilis* (n. 4.) Stem like that of Lavender, branched, and white. Peduncles ſtraight, uſually three-flowered at the end. Calycine ſcales brown at the edge [e].

Native of the South of Europe. Cultivated in 1570, by Matthias de L'Obel. It flowers from july to ſeptember [f].

4. Leaves heaped at bottom. Peduncles naked. Calycine ſcales black at the edge [g]. Stems firſt procumbent, then erect. Calyxes cylindric, patulous and membranaceous at the end. Very many, naked, female florets in the circumference.—Native of Spain, Italy, Iſtria, Carinthia, the Valais, Paleſtine, and the Cape of Good Hope [h]. Ray found it on walls and rocks about Meſſina and Sicily, abundantly.

Introduced 1774, by Monſ. Richard. It flowers in july and auguſt [i].

5. The whole plant hoary. Stems almoſt ſimple, columnar, ſtriated, with ſhort lateral branches. Leaves a finger's length, reflected at the edge, ſomewhat tomentoſe underneath. Panicle terminating, ſubdichotomous. Calyx ſubovate, ſhorter by half than the flower and down. Flower purple, mixed with the down. It has the air of *C. cinerea* (n. 17.) Found at the Cape, by Chevalier Thunberg [k].

6. This reſembles *C. ſaxatilis* very much, but the flowering ſtems have axillary bunches of ſmaller leaves. The leaves are broader, ſhorter, more obtuſe, all except the lowermoſt white on both ſides. Calycine ſcales not acute and patulous, but rather obtuſe, and cloſely imbricate. Corollas yellow, with very numerous florets. Smell ſtrong.—Native of Arabia [l].

It is very nearly allied to *C. ſaxatilis*, but the leaves towards the baſe are leſs attenuated and widened at the inſertion; the peduncles are ſhorter and thicker, with one or two ſcales, which are lanceolate, but not briſtle-ſhaped; outer calycine leaflets ovate, brown at the tip, the middle ones linear, obtuſe, with a brown line on the back, whereas in the ſaxatilis all the leaflets are lanceolate and acute; branches very thickly tomentoſe, as are alſo the leaves, but grow bald by age. In the cultivated plant the leaves are twice as broad, and not rolled back on the edge [m].

7. Leaves rugged on both ſurfaces, with four or five teeth on each ſide. Peduncles axillary, towards the end of the branches, becoming finally ſix times the length of the leaves.—Native of the Eaſt-Indies [n].

8. This has the air of an *Aſter*. Corymb ſubfaſtigiate. Flowers as in *C. ſaxatilis* (n. 4.) radiated.—Native of North America [o].

Introduced 1773, by Mr. William Young. It flowers in auguſt and ſeptember [p].]

9. From a thick fibrous root ariſe many upright ſtalks. Leaves rough, decurrent. The upper part of the ſtalk divides into many ſmaller branches, with leaves of the ſame form, but ſmaller. Flowers terminating, in round bunches, yellow, appearing in july. The ſeeds ripen in autumn.

[Native of Canada. Cultivated 1759, by Mr. Miller [q]. Compare with this *Inula biſrons*, a native of the South of Europe, and ſuppoſed not to be a different ſpecies, though it has a ray to the flower.

10. Native of the Eaſt-Indies.

11. Branches herbaceous, with a few ſcattered hairs on them. Leaves alternate, wedge-ſhaped at the baſe, green on both ſides, with a few ſcattering hairs, having three or four narrow ſerratures; not ſcabrous. Peduncles axillary, towards the top, with from two to four flowers. Calyx before it opens woolly.—Native of the Eaſt-Indies [r].

Loureiro deſcribes the ſtem as ſuffruticoſe, eight feet high, climbing, round and branching. Leaves broad-lanceolate, attenuated at the baſe, having a few teeth, ſubpubeſcent, ſcattered, petioled. Flowers yellow. All the corollets, both hermaphrodite and female ſhort, immerſed in a ſimple down.

12. Branches ſubhirſute, ſtriated, ſimple. Lower leaves obovate, upper ovate-lanceolate, veined, hardiſh, rugged on both ſurfaces, on very ſhort petioles. Racemes terminating and axillary, ſimple, ſcarce a ſpan in length, ſpreading, reflex or crenate downwards. Flowers alternate, ſeſſile, turned up, rounded: calycine ſcales ovate, the inner lanceolate [s]. Perhaps after all not diſtinct from C. arboreſcens, n. 20.

Native of Madagaſcar and Vera Cruz.

13. Stem ſuffruticoſe, ſix inches high, upright, round, hairy, whitiſh, branched. Leaves very white, quite entire, alternate. Flowers purple, peduncled, heaped. It has a pleaſant ſmell [t]. Mr. Miller ſays, that the peuncles are woolly, nine inches high, one, two or three-flowered, and that the flowers are of a dirty yellow. [According to Zanoni they are of a golden colour. The peduncles thicken towards the top. It ſometimes varies with a ſhort recurved ray [u]. Native of Candia, Sicily, and Cochinchina. —*Cultivated 1714, by the Dutcheſs of Beaufort* [x]. Boccone, who firſt deſcribed the plant, ſays that he had it from Alexander Balam, an Engliſhman, his very good friend, and well ſkilled in Botany.

14. *Root* annual. *Stem* erect, roundiſh, branched, ſlightly tomentoſe, ſpotted with purple; the branches erect, ſcattered. *Leaves* alternate, ſerrate, with acute

[a] Woodw. Mſs. [b] Linn. mant. [c] Haller. [d] Morifon. [e] Linn. mant. [f] Hort. kew. [g] D'Aſſo. [h] Linn. ſpec. [i] Hort. kew. [k] Linn. ſuppl. [l] Linn. mant. [m] Vahl. [n] Linn. mant. unequal,

unequal teeth, narrowed at the base into the petiole, scabrous on the upper surface, smooth and veined on the lower. *Flowers* in panicles at the ends of the branches, on long peduncles thickening towards the flower, and having one leaf on each: a solitary peduncle terminates the stalk. Common calyx ovate, converging at top; scales linear, the inner of the same length with the tubes of the corollas, the outer elongated, and diverging every way. Corolla uniform, consisting of twenty-five to forty hermaphrodite, red florets; those of the ray reflex: tube very slender, narrowed towards the border, which is oblong-ovate, the divisions lanceolate, erect, almost converging. Anther white, with five black lines. Germ striated: style the length of the corolla: stigmas two, reflex. Seed obconic, longitudinally striated. Down bristle-form, of the same length with the tube of the corolla. Receptacle dotted.—Since there are no female florets, this is rather a species of *Serratula*[x]. Jussieu doubts whether it belongs to this genus; the flowers being subsolitary, almost all the florets hermaphrodite, and the calycine leaflets all equal in length, the inner ones wider, the outer linear, and resembling a calycle[z]. The leaves have an exceeding bitter taste. Native of the East-Indies. Introduced 1770, by Monsr. Richard. *It* flowers in august and september, and is biennial[a].

15. Down ferruginous[b]. Perhaps a species of Baccharis[c].—Native of the East-Indies.

16. Stem erect, panicled, pubescent. Leaves hoary, lanceolate-elliptic, repand-serrate, remote. Corollas purple. Styles short. Down longer than the calyx[d].—Annual. Native of the East-Indies.

17. This is an odoriferous plant, with an upright shrubby stem, four feet high, the branches rising in form of a corymb. Leaves sessile, alternate. Flowers purple, lateral and terminating, several together; the corollets so short as not to emerge from the calyx[e]. Native of the East-Indies and Cochinchina.

18. Stem suffruticose, four feet high, upright, round, smooth, branched at top. Leaves hardish, petioled, alternate. Flowers yellow, peduncled, terminating. Receptacle subvillose[f]. This has seldom more than three flowers crowded together[g].—Native of China, Cochinchina, Java and Amboina.

19. Stem herbaceous, a foot high, upright, simple, round, hairy, having few leaves; these are oblong, sharpish, toothletted, hairy, scattered. Flowers yellow, crowded, terminating. Calyx hairy, short. Naked female florets in the ray[h].] According to Miller, it is a biennial plant, about two feet high, with purple flowers in oblong spikes. [Burmann says, it varies with entire and toothletted leaves, and that there are several varieties of it.

According to Linneus, the stem is somewhat villose. Leaves oblong or oval, underneath very hirsute and pale. Flowers in racemes crowded: and it has the calyx of an After. Native of Java, China and Cochinchina.

20. This is a shrub with a depressed rugged stem. Branches divaricate, subdivided, bent down, diverging, villose with a blackish shagginess. Leaves petioled, alternate, broad-lanceolate, nerved, wrinkled, pubescent. Racemes terminating and axillary, erect; flowers subsessile, alternate, pale purple. Calycine scales pressed close, pubescent. Corolla uniform: twelve hermaphrodite corollets in the circuit, a little higher than the others, giving the flower a radiate appearance[i]. It commonly rises to the height of three feet and a half or more, in the low lands of Jamaica. The branches bend generally forwards, and bear their flowers in loose spikes, (or rather racemes) along their extremities, where they are disposed in a gradual succession on the upper sides only[k].

21. Native of South America.

22. It is hairy, and rises generally to the height of two feet and a half or more. The leaves are somewhat hoary. The flower-branches are very long and slender, and disposed in form of spikes at the top; the lower flowers are in threes, the upper solitary. The seeds are subhirsute[l].

Native of Jamaica and Carolina.

Introduced 1783, by Mr. William Young. It flowers in august and september[m].

23. Root annual. Stature of *Filago*. Stem about a palm in heighth, erect, villose-tomentose, as is the whole plant. The leaves run very far down the stem, as in *Genista sagittalis*. Glomerules of flowers ash-coloured, from the axils of the leaves, globular.—Native of India[n].

24. Root-leaves larger than the rest, stiffer, smoother, obovate, with red veins, widely serrate, and waved between the serratures. Stem-leaves oblong, sublanceolate, soft, villose, serrate at the end, sinuate in the middle, subpinnate at the base, the whole edge serrate-toothed, subdecurrent; with two or three foliaceous spreading pinnas on each side. *Stem* erect, stiff, a foot high, reddish, hairy, branched: the branches erect, simple. *Flowers* from the top of the stem, peduncled, scattered in various ways. Calyx ovate; leaflets linear, spreading at the end; the outer broader, the inner formed into a cylinder. Florets minute, white; with minute, linear rays. Pistils very long, erect.—It seems intermediate between this genus and *Baccharis*. The scent is that of *Stachys foetida*, but more pleasant.—Native of the East Indies, in moistish places[o].

25. Stem proliferous, dichotomous, smooth; when the branch is terminated by a panicle immediately under it, the stem is divided into two branches, which are subdivided in the same manner. Leaves very short, sharply serrate, somewhat scabrous, with very minute, elevated dots. Corymbs terminating, simple. Peduncles hirsute, cloathed with subulate bractes. Calyx purplish. Flowers yellow.—All the plants in the Canary islands, even these of the *Syngenesia* class, grow like shrubs[p].

Native of the island of Teneriffe. Mr. Fr. Masson. Introduced 1780. It flowers in july and august[q].

26. This is easily known by the silky whiteness of the branches, leaves and peduncles, and by its yellow flowers. Leaves channelled, very long and flaccid. Branchlets simple, but with panicles of flowers at the end; the shorter ones are terminated with a panicle of very few flowers. Calyxes smooth, with subulate, yellow scales. The bark and wood have an acrid, pungent taste; and the inhabitants use it against the toothach[r].

Native of the Canary islands. Mr. Francis Masson. Introduced 1779[s].

27. *Stem* erect, a foot and half in height, somewhat striated, pubescent, and somewhat viscid. *Leaves* alternate, sessile, scarcely half-stem-clasping, spatulate or obovate-lanceolate, bluntish, subpubescent, having usually about five teeth, but entire at the base. Branches from the upper axils. *Flowers* terminating, four or five, roundish, on purplish peduncles. Corollas yellow, with minute florets; in the ray naked, and very abundant: pistils yellow, quickly vanishing; surrounding the disk with a kind of broad downy ring.—Annual[t].

Native of Egypt. Introduced 1778, by Monsr. Thouin. It flowers in july[u].

28. Native of the island of St. Helena. Introduced 1772, by Sir Joseph Banks Bart.—It flowers in November[x].

29. Native of the Cape of Good Hope. Mr. Francis Masson. Introduced 1774.—It flowers from june to august[y].

30. Annual. *Stem* taper, herbaceous, a foot and half in height, covered lightly with a mealy down,

and branching out almoſt the whole length. Branches ſlender, ſpreading almoſt horizontally, except that they turn up towards the end. *Leaves* oblong-oval, ſoft, bluntly indented on their edges; the lower about four inches long, and two inches and a quarter broad in the middle; hoary green on their upper, and pale green on their under ſurface, with a ſtrong, pale midrib: the leaves on the branches diminiſh gradually in ſize, but are of the ſame form. The *flowers* are produced at the end of the branches on ſhort peduncles, for the moſt part ſuſtaining three flowers. Calyxes ſoft and ſwollen in the middle; ſcales ſmall, acute. Corollas purple. The flowers appear in july, and there is a continual ſucceſſion till the cold of autumn puts a ſtop to them. The early flowers are generally ſucceeded by good ſeeds in favourable ſeaſons.—Native of the northern parts of China; and cultivated 1758, by Mr. Miller, who had the ſeeds from John Browning, Eſq. Maſter in Chancery, a curious cultivator of exotic plants at Chelſea [z].]

31. This riſes with a woody ſtalk ten or twelve feet high, dividing into many branches, the bark of which is covered with a brown nap. Leaves alternate, on ſhort petioles. Flowers in looſe ſpikes ranged on one ſide: they are white, and are ſucceeded by long flat ſeeds. It grows naturally at La Vera Cruz in New Spain, whence Dr. Houſtoun ſent the ſeeds to Mr. Miller.

32. This has a perennial root, from which ariſe ſeveral upright ſtalks three feet high. The flowers are produced at the end of the ſtalks in round bunches; they are ſmall, and of a purple colour; and are ſucceeded by oblong flat ſeeds. Native of La Vera Cruz in New Spain.

33. Stem ſtrong, woody, fourteen or ſixteen feet high, covered with an aſh-coloured bark, and divided at top into many woody branches. Leaves alternate, on ſhort petioles. The branches are terminated by roundiſh bunches of white flowers, on long peduncles, ſeveral together. Sent from La Vera Cruz by Dr. Houſtoun.

34. This is an annual plant, growing in low moiſt places, where the water ſtands in winter. It has an herbaceous branching ſtalk, one foot high, with one oval ſeſſile leaf at each joint, covered with a white hairy down. The flowers are produced from the ſide of the branches on ſlender petioles, each for the moſt part ſuſtaining three flowers, which are white, and are ſucceeded by chaffy ſeeds. The whole plant is viſcous. Sent by Dr. Houſtoun from La Vera Cruz.

35. Root perennial. Stem three feet high. Leaves four to five inches long, and one and a half broad in the middle, rough like thoſe of Comfrey. Stems terminated by branching peduncles, each ſuſtaining ſeveral yellow flowers, not much unlike thoſe of the common ſort. Native of La Vera Cruz, whence it was ſent by Dr. Houſtoun.

36. This has a climbing ſhrubby ſtalk, fourteen or ſixteen feet high, dividing into many branches. Leaves the ſize of thoſe of the Bay-tree, and full as thick in their texture, having many deep tranſverſe neryes, running from the midrib to the ſides; and of a pale green colour. Flowers large and white, produced in long ſpikes, ranged on the upper ſide only, from the ſide of the branches, and pointing upwards. They are ſucceeded by flat dark-coloured ſeeds. Sent from La Vera Cruz by Dr. Houſtoun.

37. Stalk ſhrubby, ſix or ſeven feet high, dividing into ſeveral woody branches. Flowers white, ſucceeded by oblong flat ſeeds. Native of Carthagena in New Spain, whence it was ſent by Mr. Robert Millar.

38. This riſes with a ſhrubby ſtalk eight or ten feet high, dividing into many long ſlender branches. Leaves three inches long, and three quarters of an inch broad in the middle; the ſmaller branches are ſet with very narrow, oblong, pointed leaves, which grow cloſe to the ſtalks; and at each joint is produced one pretty large white flower, with a purple calyx; theſe flowers come out the whole length of the ſmall branches, ſitting cloſe to the baſe of the leaves, ſo that the plants make a pretty appearance in flower.

Native of the ſame country, and ſent over by Mr. Millar.

39. This has a ſtrong woody ſtem, riſing ten or twelve feet high, divided at top into many ſhort woody branches, whoſe joints are very cloſe to each other. The leaves come out alternate on every ſide the branches, to which they ſit very cloſe; they are ſmooth, one inch long, and half an inch broad, ending in acute points, having three longitudinal veins. The flowers are white, and produced in ſhort cloſe ſpikes, which come out from the ſide of the branches, and are ſucceeded by oblong flat ſeeds.

Native of Carthagena in New Spain, and ſent over by Mr. Millar.

40. This riſes with a ſhrubby ſtem to the height of ſix or ſeven feet, dividing into ſeveral branches, which have a dark brown bark. Leaves ſmooth, having three longitudinal veins, ſtanding on ſhort foot-ſtalks, placed alternate on every ſide the branches. The flowers are produced on long naked peduncles, which extend five or ſix inches beyond the end of the branches; theſe are purple, and form a kind of round bunch: the calyx of the flower is compoſed of ſhort chaffy ſcales.

It grows naturally at Campeachy, whence the ſeeds were ſent by Mr. Robert Millar.

41. Stem ſhrubby, ten or twelve feet high, ſending out many ſtrong woody branches, covered with a dark-coloured bark. The flowers are purple, and are ſucceeded by flat ſeeds. Native of Campeachy.

42. This riſes with a ſhrubby branching ſtalk four or five feet high. The lower branches and ſtalk have ſpear-ſhaped leaves four inches long and one inch broad in the middle, on ſhort petioles: the leaves on the upper branches are much narrower, and end in acute points. The flowers are purple, and are produced in round bunches at the end of the branches.

[Browne ſays, that it ſeldom riſes ſixteen or twenty inches in height; that the ſtalk is generally pretty ſimple below the middle, but towards the top throws out many branches, which reach nearly to an equal height, and carry their flowers in a ſhady ſpreading form at the top; that the ſmell is agreeable, and that it is kept by ſome people among their cloaths, to preſerve them from moths and other inſects.

Native of Jamaica, in the low marſhy lands.

43. Native of Jamaica.]

PROPAGATION AND CULTURE.

1. Common great Fleabane being a native, is ſeldom allowed a place in gardens. If the ſeeds be permitted to ſcatter, the plants will come up the following ſpring, and require no other care but to keep them clean from weeds.

9. This is propagated by ſeeds, which may be ſown on a bed of light earth in the ſpring, and when the plants come up, they ſhould be thinned where they are too near, and kept clean from weeds; the following autumn they may be tranſplanted where they are deſigned to remain, and require no other care but to keep them clean from weeds. The ſecond year they will flower and produce ripe ſeeds, and will continue two years if the ſoil is not too good, for theſe plants often rot, when they are planted in a rich ſoil.

13. This rarely producing ripe ſeeds in this country, is propagated here by ſlips, which taken from the old plants in june, and planted on an eaſt-aſpected border, and covered with hand-glaſſes, will take root in ſix or eight weeks. But theſe ſlips muſt be frequently, but gently refreſhed with water, and the glaſſes ſhould be ſhaded in hot weather; and after they have been planted a fortnight, the glaſſes ſhould be raiſed on one ſide to admit air to the cuttings; and when they have taken root, they ſhould be

be gradually expoſed to the open air. In autumn theſe ſhould be carefully taken up, preſerving the earth to their roots; ſome of them may be planted in pots, that they may be ſheltered under a frame in the winter; and the others ſhould be planted in a warm border of dry poor earth, where they will endure the cold of our ordinary winters very well, and continue many years. This is preſerved in gardens, more for the beauty of its ſilvery leaves than its flowers, which have not much to recommend them.

[14. Produces ſeeds freely, by which it may be propagated.]

19. This ſort is propagated by ſeeds, which ſhould be ſown in pots in the autumn, if they can be procured at that ſeaſon; but the pots ſhould be placed in a garden-frame in winter, to prevent the ſeeds ſuffering by cold and wet. If the ſeeds are ſown in the ſpring, the plants rarely come up the ſame year, therefore it will be proper to ſcreen this in winter; when this is obſerved, the plants will riſe the following ſpring. When the plants are fit to remove, they ſhould be each planted in a ſeparate pot, and placed into a very moderate hot-bed, where they muſt be ſcreened from the ſun until they have taken root; after which they ſhould be gradually hardened to bear the open air, into which they ſhould be removed the beginning of june, placing them in a ſheltered ſituation, where the ſecond ſeaſon they will flower, and if the ſummer is good, they will ripen their ſeeds.

6, 7, 10 to 12, 14 to 21, 22 to 24, 27, 31 to 43. Theſe are too tender to thrive in the open air in this country; the ſeeds therefore muſt be ſown upon a hot-bed the beginning of april, and when the plants are fit to remove, they muſt be each tranſplanted into a ſmooth pot filled with light ſandy earth, and plunged into a hot-bed, obſerving to ſcreen them from the ſun till they have taken new root; then they muſt have free air admitted to them every day, in proportion to the warmth of the ſeaſon; they muſt alſo be frequently watered in warm weather, but they ſhould not have it in too great plenty. As the plants advance in ſtrength, they muſt have a greater ſhare of air; and if the ſeaſon is warm, they may be expoſed to the open air for a few weeks in the heat of ſummer, provided they are placed in a warm ſituation; but if the nights prove cold, or much wet ſhould fall, they muſt be removed into ſhelter: if theſe plants are placed in a moderate ſtove in winter, they will thrive better than in greater heat, and in ſummer they ſhould have a large ſhare of air. With this management the plants will flower well in july, but in general they will not perfect their ſeeds here.

[22. And ſome other of the perennial ſorts may be increaſed by parting the roots.

26, 28, 29. Grow readily from cuttings.

27. Muſt be propagated from ſeeds.]

30. The ſeeds ſhould be ſown upon a moderate hot-bed the beginning of april; when the plants are fit to remove, they ſhould be tranſplanted into a freſh hot-bed, obſerving to ſhade them from the ſun till they have taken new root. In june they may be gradually hardened to the open air; and part of them may be planted in warm borders, where they will flower, and if the ſeaſon prove warm, ripen their ſeeds: but it will be prudent to keep ſome plants in pots, placed in an airy glaſs-caſe, in order to ſecure good ſeeds.

34. Sometimes ripens its ſeeds, if the autumn prove favourable; but there is little beauty in this ſpecies. The ſeeds of the other South-American ſorts muſt be procured from that country; and being long in coming, they rarely vegetate the firſt year.

36. Makes a fine appearance in the ſtove when it flowers, and as it retains its leaves all the year, in the winter it affords an agreeable variety among other tender plants.

[Moſt of the ſpecies require the protection of the bark ſtove, as 6, 7, 10, 11, 12, 14 to 21, 23, 24, 27, and 31 to 43.

3, 4, 5, 13, 22, 25, 26, 28, 29, 30, may be kept in a Green-houſe, dry Stove or glaſs caſe.

2, 8, 9 are hardy Perennials.

DESCRIPTION, *&c.*

[This is a lofty elegant tree, with a handſome head: the extreme branches at the axils are flexuoſe, and have a ſmoothiſh bark of a browniſh aſh colour. Leaves alternate, pinnate, the midrib or rachis round and four inches long, leaflets three or four pairs without an odd one, lanceolate-ovate, ending in a blunt point, quite entire, ſhining, ſubcoriaceous, with ſeveral obliquely aſcending veins, the middle nerve prominent beneath, and ferruginous; they are from two to three inches long, and on ſhort petioles; the inner ones narrower by half than the others; the two uppermoſt oppoſite, but one of theſe frequently wanting, ſo that the leaf then appears to be unequally pinnate: the reſt are alternate. Racemes axillary, ſolitary, ſpreading, ſtiff, round, the length of the pinnas, looſely divided into about eight alternate, lateral common peduncles, an inch and half in length, with white flowers ſitting cloſely on them. The germ as it grows, from flat becomes globular.

Native of South America, frequent about Tolu, ſixty leagues from Carthagena, promiſcuouſly with the trees which yield balſam of Tolu, Peru, *&c.* [a]

Introduced into Jamaica by Mr. Robert Millar, ſurgeon: [here in 1788, by Mr. Alexander Anderſon [b].

From this tree is obtained in very conſiderable quantities, by perforating the trunk, fluid balſam or reſin, which thickens by degrees: and which is known in medicine by the title of Balſamum Capivi.

This balſam has an agreeable ſmell, and a bitteriſh taſte; and when agitated with water, in ſome degree unites with it, rendering the liquor turbid and milky, but ſoon ſeparates, and riſes to the ſurface on ſtanding. Dropt on ſugar, or triturated with thick mucilages, or with whites of eggs, it becomes more permanently miſcible with water into an uniform milky fluid: it is generally taken in this

[a] Jacquin. [b] Hort. kew.

form,

form, or mixed with powdery or other matters into a bolus or electary. It mixes eaſily with diſtilled oils, and diſſolves in rectified ſpirit of wine into a tranſparent fragrant liquor, more agreeable than the balſam itſelf.

Balſam of Copaiba has been employed principally, and preferably to the other balſams, in fluor albus, and in ulcerations of the urinary paſſages. Fuller ſays he has known dry deep coughs, coughing up of blood and pus, voiding of chyle inſtead of urine, with great pain and weakneſs, cured by it; and that, notwithſtanding the warmth and bitterneſs of its taſte, he has found it to agree in hectic caſes. He obſerves that it gives the urine a bitter taſte, but not a violet ſmell, as the turpentines do; and that if taken in doſes of two or three drams, it proves, like them, purgative. The uſual doſe is from ten to thirty or forty drops.

In too large doſes, or too long continued, it has been found productive of conſiderable inconveniences; exciting febrile heats, pains in the head, &c.]

PROPAGATION AND CULTURE.

If freſh ſeeds of this tree could be procured from South America or the Weſt Indies, it might be raiſed from them. [It may alſo be increaſed from cuttings, but not very readily.] It muſt be conſtantly preſerved in the bark ſtove.

COPALLI. See *Rhus copallinum*.

COPPICES. See *Planting*.

[COPROSMA. (*From κοπρος, dung; and οσμη, ſmell: the firſt ſpecies ſmelling very ſtrong like dung.*)

Leaves ovate ſetaceous-ſerrate oppoſite, ſtem and branches flexuoſe-ſcandent.]

DESCRIPTIONS, *&c.*

1. It is an annual plant, about two feet high, and dividing into ſeveral branches. Leaves ſome ſpear-ſhaped, others oval, ſome almoſt heart-ſhaped, deep-green, ſlightly indented on their edges, having near their baſe two briſtly reflex ſegments; they are on very long ſlender petioles; eſpecially the lower one. Flowers ſeſſile, ſolitary, yellow. [Stipules ſimple, red at the baſe. Leaves three-nerved. Capſules fuſiform, five-celled, furrowed, with about five teeth, or obtuſe [a]. Very obſcurely five-cornered, leſſening at top into a beak. Seeds of an almoſt pyramidal form, dark brown, fixed in a double row along the middle edge of the partitions [b].]
Native both of the Eaſt and Weſt Indies, and of Africa. Rauwolf ſays it is ſown in great plenty about Aleppo as a pot-herb, the Jews boiling the leaves to eat with their meat.
[Cultivated 1731, by Mr. Miller [c]. It flowers in july and auguſt, and the ſeeds ripen in autumn.
2. Root annual. Stems ſmooth and even, ereſt, a foot in height, round, green. Stipules ſetaceous, ſmall. Leaves alternate, petiolate, marked with lines, naked, the under ſurface ſcabrous, lanceolate, wave-ſerrate. Peduncles nearly oppoſite to the leaves, ſhort, two-cleft or two-flowered. Calyxes angular. Petals narrow, pale yellow. Capſules linear, of a triangular priſmatic form, ſcabrous, the angles ſtreaked with a line, obtuſe at the end, and ſimple [d].
Jacquin remarks, that the whole plant is ſomewhat rugged, that the peduncles ſuſtain from one to three flowers, on very ſhort pedicels, that the calyx is obſcurely tinged with purple, that the petals are obovate, either ſlightly emarginate or entire; he calls the pericarp a ſilique, and ſays that it is two inches long, three-celled and three-valved; and that the ſeeds, which are ſmall and blue, are ranged in a double row along the valves.
Native of Arabia, where it was found by Forſkæhl.
3. Stem ſmooth and even, green. Stipules three-parted, ſetaceous. Leaves marked with lines, lanceolate, wave-ſerrate. Capſules linear, ſcabrous. Styles three, very much divaricated, bifid [e].
Native of the Eaſt Indies.]
4. Stem ſtrong, two feet high, divided at top into two or three branches. Leaves on long petioles, and between them ſeveral ſmaller leaves nearly of the ſame form, ſitting cloſe to the branches. The flowers come out ſingly on the ſide of the branches.
[Stem roughiſh, purpliſh, with divaricating branches. Stipules ſetaceous. Capſules linear, hexangular, the angles compreſſed, each pair approximating. Styles three, bifid. The teeth at the end of the capſule divaricate very much [f]. Capſule terminated by three very ſpreading beaks, bifid at the end: the valves have obſcure tranſverſe wrinkles within, inſtead of partitions; on the outſide they have a double wing at the back, which is notcheletted, and ſomewhat waved. Seeds ſmall, variouſly cornered, blackiſh [g].]
Native of the Weſt Indies. [Cultivated 1739, by Mr. Miller [h].]
5. This riſes with a ſlender ſtalk about three feet high, ſending out ſeveral weak branches. At each joint is one leaf of an oblong heart ſhape, ending in a long acute point, ſerrate, and on a ſhort petiole. The flowers come out ſingly on the ſide of the branches, to which they ſit very cloſe; they are ſmaller than thoſe of the former ſorts.
[The leaflets of the calyx are concave, bent in, dotted on the outſide, and ſhorter than the corolla. Petals emarginate [i].
Native of the Eaſt-Indies, and China. Cultivated 1731 by Mr. Miller [k].
6. This ſhrub grows to the height of a man, with many round branches, the young ones villoſe. Leaves alternate, petioled, crenate, thickiſh, veined, hoary underneath. Peduncles lateral, umbelled, having from four to ſeven flowers, void of ſcent, each on its proper pedicel. Calycine leaflets oblong, concave, villoſe. Petals yellow, roundiſh, ſpreading very much, the length of the calyx. Stamens the length and colour of the corolla. Germ villoſe: ſtyle the length of the ſtamens: ſtigma obtuſe. Capſule ovate, a little bent in, lanuginoſe, obtuſe, two-celled.—It varies in Jamaica with oblong leaves [l]. This variety is figured by Jacquin, hort. t. 57. f. 2.
Thunberg deſcribes his C. tomentoſus thus. *Stem* ſhrubby, round, ereſt, branched, purple, ſmooth, two feet high and more. Branches alternate, at bottom purple and ſmooth, at top tomentoſe, ereſt, wand-like. Branchlets filiform, very ſpreading, tomentoſe. *Leaves* alternate, petiolate, nerved, ſpreading. Petiole very ſhort, tomentoſe; as is alſo the calyx. *Flowers* axillary and terminating, uſually ſolitary. Corolla orange-coloured. Capſule cylindric, woolly.—This is very diſtinguiſhable from the other ſorts by its tomentoſe leaves. Japan, flowering in ſeptember and october.
Native of the Weſt-Indies and Japan.

[a] Linn. mant. [b] Gærtner. [c] Mort. kew. [d] Linn. mant. & ſyſt. [e] Ibid. [f] Ibid. [g] Gærtner. [h] Hort. kew. [i] Lin. ſyſt. [k] Hort. kew. [l] Jacquin.

7. *Stem* ſhrubby, two feet high and more, ſmooth. *Leaves* from alternate buds many, petiolate, ſubcordate, ovate, acuminate, gaſh-ſerrate, the ſerratures ſerrate, acute, all ſubſetaceous; nerved, villoſe, eſpecially the nerves underneath. Petiole a line in length. Flowers terminating, ſolitary, on ſhort peduncles. Corolla dark-yellow or orange-coloured.—Native of Japan, where it is alſo cultivated for the elegance of its flowers, which appear in february and the following months [m].

8. Root annual. Stem upright, round, branched, eſpecially at top, from two to three feet high. Leaves alternate, lanceolate, acute, finely ſerrate, on ſhort petioles, ſomewhat hairy, wrinkled on both ſides. Flowers without ſcent, axillary, peduncled, ſolitary or in pairs. Calycine leaflets hiſpid, ſpreading very much, flat, lanceolate-linear, acuminate, yellowiſh green. Petals yellow, ſhorter than the calyx, ſpreading much, very blunt, narrowed a little towards the baſe. Stamens the ſame length and colour with the petals. Germ oblong, columnar, hiſpid, with whitiſh, upright hairs. Style filiform, the length of the ſtamens: ſtigma capitate. Capſule linear, acute, hiſpid, brown, near an inch long, two-furrowed, two-valved. Seeds black, angular, ſmall.

Native of the Weſt Indies [n].

9. It is an herbaceous plant, but branched like a ſhrub, with a round ſmooth ſtem, and alternate upright pubeſcent branches. Leaves petioled, alternate, ſmall, nerved, ſmooth, with ſmaller leaves in the axils. Stipules ſubulate, oppoſite [o].

Stem almoſt ſhrubby, erect, panicled, ſubpubeſcent. *Leaves* lanceolate or ovate-oblong, equally ſerrated without an elongated tooth at the baſe. Peduncles one-flowered (few-flowered, oppoſite to and ſhorter than the leaf, flowers ſmall, yellow, nodding, *Swartz.*) lateral, without bractes. Germs hairy. Siliques two-valved, compreſſed.—The vernal flowers have no petals, a four-leaved calyx, and four ſtamens: the autumnal, have five petals, a five-leaved calyx, and many ſtamens [p]. Cultivated 1732, by Mr. Miller. It flowers from june to auguſt [q]: in its own country almoſt the whole year. Very common in all the ſugar colonies, in dry ſandy places; ſeldom riſing above two feet and a half. It is generally uſed for beſoms by the negroes [r].]

10. Height about two feet, dividing into ſmall branches. Flowers very ſmall, pale yellow, ſucceeded by ſwelling, rough, four-cornered ſeed-veſſels, about an inch long, flatted at top, where there are four reflex horns, giving them ſome reſemblance to the Clove.

Native of both Indies.

11. Height three feet, with ſeveral weak ſide branches. Leaves about three inches long, and one inch broad in the middle, leſſening gradually to both ends, ſitting cloſe to the branches. The flowers come out ſingly oppoſite to the leaves; they are very ſmall, of a pale yellow, and are ſucceeded by ſeed-veſſels near two inches long, flat, two-celled, with ſmall angular ſeeds.

Native of Carthagena in New Spain.

12. This riſes with a ſtrong herbaceous ſtalk between three and four feet high, ſending out ſeveral ſide branches, which grow erect. Leaves on long ſlender petioles: and between them many ſmaller leaves nearly of the ſame form, ſitting cloſe to the branches. The flowers come out from the ſide of the branches, on ſhort peduncles, are very ſmall, of a pale yellow, and are ſucceeded by flat ſeed-veſſels near three inches long, ending in two horns; they are two-celled, and filled with ſmall angular ſeeds.

Native of Jamaica, whence the ſeeds were ſent by Dr. Houſtoun.

[13. Branches round, ſmooth. Leaves petioled, narrow, blunt, the lower ſerratures not briſtle-ſhaped. Fruits aſh-coloured with hairs, three-valved.—Native of the Eaſt Indies [s].

14. Stem round, ſlightly angular by the decurrent leaves, ſmooth, erect, two feet high. Leaves alternate, petioled, obliquely cordate, ovate, villoſe, patulous, two inches long. Flowers at the ends of the branches, yellow.

15. Stem erect, ſmooth. Branches round, purple, erect. Leaves alternate, petioled, ſerratures large, ſetaceous at the tip, the upper ſurface very finely villoſe-ſcabrous, the under ſmooth, two inches long, patulous.

16. Stem round. Branches oppoſite, ſimilar, divaricating. Leaves on very ſhort petioles, rounded at the baſe, acuminate, an inch long. At the ends of the branchlets are ſolitary, yellow flowers.

Theſe three are natives of Japan [t].]

PROPAGATION AND CULTURE.

All theſe ſorts are too tender to thrive in England in the open air, therefore their ſeeds muſt be ſown on a hot-bed in the ſpring; and when the plants are come up fit to remove, they ſhould be tranſplanted on a freſh hot-bed to bring the plants forward, otherwiſe they will not ripen ſeeds. After the plants are rooted in the new hot-bed, they muſt have free air admitted to them every day, in proportion to the warmth of the ſeaſon, for they muſt not be drawn up weak; when the plants have obtained ſtrength, they ſhould be tranſplanted each into a ſeparate pot, and plunged into a hot-bed, obſerving to ſhade them from the ſun till they have taken root; then they muſt have a large ſhare of air every day, and ſhould be frequently refreſhed with water; and in june they ſhould be gradually inured to the open air, and part of them may be ſhaken out of the pots, and planted in a warm border, where, if the ſeaſon proves warm, they will flower and perfect their ſeeds; but as theſe will ſometimes fail, it will be proper to put one or two plants of each ſort into pots, which ſhould be placed in a glaſs-caſe, where they may be ſcreened from bad weather, and from theſe good ſeeds may always be obtained. The ſixth ſort may alſo be treated in the ſame manner during the ſummer ſeaſon, but in autumn the plants muſt be removed into the ſtove, and plunged into the bark-bed, and theſe will flower early the ſecond year, and ripen ſeeds.

CORDIA. (*So named by Plumier, from Euricius Cordus, whoſe true name was Henricus Urbanus, and Valerius his ſon, German botaniſts of the ſixteenth century.*)

Swartz prodr. 47.
Leaves elliptic acuminate entire coriaceous, branches compound diffuſed, drupes acuminate.

DESCRIPTIONS, *&c.*

1. Leaves like thoſe of the Alder, ſerrate-angulate, ſcabrous underneath[a], three inches long, oppoſite, flat, entire, obtuſe, on a round petiole, half an inch in length. Peduncles panicled, terminating, ſubcorymbed. Petals white, revolute. Fruit inferior, red, nearly an inch in diameter[b]. According to Gærtner, it is a black, berried drupe. Fleſh ſuculent. Shell bony, ovate, emarginate at top and bottom, perforated, of a turgid lenticular form, obſcurely ſcrobicular, ſubquadriloculare; two cells fertile, the others uſually barren or quite obliterated.

The timber of this tree is tough and ſolid, it is uſed for procuring fire by friction; the leaves bruiſed with thoſe of Datura Metel are applied to the ſore head in the head-ach; a glue is prepared from the fruits, which are alſo eaten by children[c].

Native of Arabia and the Eaſt Indies. Cultivated 1640[d].

Mr. Miller ſays it was very rare in this country till the year 1762, when the Daniſh travellers ſent ſome of the fruit from Egypt, and ſome plants were raiſed in the Chelſea garden.

[2. *Branches* ſtrict, tomentoſe, ferruginous. *Leaves* alternate, petiolate, tomentoſe, more ſcabrous on the upper ſurface, the ſize of Cherry leaves. *Petiole* very ſhort, ſeparating at the joint, but the baſe becoming a thorn as in *Volckameria*, rigid, and obliquely truncate on the outſide. *Raceme* from the axils of the leaves, ſimple or bifid, filiform, the length of the leaf. *Fruits* ſcattered, ſeſſile, black, the ſize of Currants. *Calyx* bell-ſhaped, obſcurely five-toothed. *Corolla* bell-ſhaped, five-toothed, twice as large as the calyx. *Style* filiform, twice bifid at top. *Stigmas* acute.—Native of the Eaſt Indies[e].]

3. Stems ſeveral, ſhrubby, eight or nine feet high, having towards the top rough alternate leaves on ſhort petioles, of a deep green on their upper ſide. Flowers terminating, in large cluſters upon branching peduncles, ſuſtaining one, two, or three flowers. Corolla large, with a long tube, ſpreading open at top, and there divided into five obtuſe ſegments; it is of a beautiful ſcarlet, and makes a fine appearance. A ſmall piece of the wood put on a pan of lighted coals, will perfume a whole houſe with moſt agreeable ſmell.

[The younger leaves are ſerrate, the full grown ſcarcely repand, the upper certainly quite entire. Petioles round. No ſtipules. Calyx cylindric, one long, with a trifid mouth. Corolla ſhaped as in Marvel of Peru, tawny-yellow, extremely wrinkled before it opens, like the Poppy. Style twice bifid.

In Jacquin's figure the colour is like that of the bloody Wall-flower, not ſcarlet[f].

It is adorned, ſays Browne, with large bunches of fine ſcarlet flowers, the moſt beautiful and agreeable of any I have yet obſerved in America.

Theſe come out at the tops of the branches fifteen or twenty together, the edge is fringed, but the ſurface ſinuous and curled; the colour at firſt is a high vermilion, becoming ſcarlet, and at length purpliſh; they have no ſcent. The fruit is in the form of an inverted Pear[h].

Native of both Indies and the Society Iſles.

From the juice of the leaves, with that of the fruit of a ſpecies of Fig, is prepared the fine red colour with which they dye their cloths in Otaheite. The Fig however will produce the colour with the leaves of ſeveral other plants[i].

Cultivated 1728, in Dr. Sherard's garden at Eltham[k].

4. Stem and branches unarmed, patulous, round, ſmooth. Leaves petioled, ſcattered, acuminate, entire, veined (eſpecially behind) ſmooth. Panicle large, compoſed of patulous, alternate, trichotomous, many-flowered branchlets; the laſt pedicels three-flowered. Flowers rather large, veined, permanent, ſhrivelling. Calyx tubular, five-toothed, ten-ſtreaked. Tube of the corolla ſpreading toward the opening, the bottom nectareous: border five cleft; the ſegments blunt, entire. Filaments faſtened to the corolla from the baſe to the middle, anthers incumbent, linear, yellow. Germ oblong, ſtyle ſhorter than the ſtamens, dichotomous: ſtigma blunt, yellow[l].

This tree riſes to a conſiderable height, but ſeldom exceeds twenty or thirty inches in diameter. It is pretty much branched towards the top, and furniſhe

[a] Linn. ſyſt. [b] Forſkæhl. [c] Forſkæhl. [d] Hort. kew. [e] Linn. mant. [f] Linn. ſpec. [g] Murray in Linn. ſyſt. [h] Dillenius. [i] Cook's firſt voyage, 2. 214, 215. [k] Dillenius. [l] Swartz.

wi

with oblong nervous leaves. The flowers have no ſcent, are very white, and grow in great numbers at the extremities of the branches; as the germ grows larger, they fade and turn of a dark or dirty brown colour, continuing upon the tree until the whole fruit, which ſeldom grows to a perfect ſtate, falls off. It is eſteemed one of the beſt timber trees in Jamaica, of which it is a native. The wood is of a dark brown colour, and gently ſtriped; it is tough and elaſtic, of a fine grain, and eaſily worked. They call it Spaniſh Elm, or Prince-wood[n]. It is found in other iſlands of the Weſt Indies, and is called by the French Bois de Chypre.

5. This tree alſo riſes to a conſiderable height, (fifty feet) but is ſeldom above twelve or ſixteen inches in diameter, ſhooting generally by a ſtraight trunk. The leaves are very large and rough. The berries are white, (reddiſh, *Sloane*) the ſize of ſmall Cherries. The heart of the tree is of a yelloviſh colour, and pretty good timber. It is called in Jamaica the broad-leaved Cherry-tree[o].

6. This tree ſeldom riſes above fourteen or ſixteen feet, (Sloane ſays fifty feet) and ſpreads pretty much at top. The leaves are rugged, obliquely veined, and diſpoſed alternately. The berries are red, ſucculent, the ſize of our ſmalleſt European Cherries, and diſpoſed in umbellated groups. Turkeys and other poultry feed much upon them; the pulp is ſweetiſh, and of a clammy conſiſtence. In Jamaica it has the name of Clammy Cherry, or Turkey-berry tree[p].

Native of Jamaica and moſt of the other iſlands. Cultivated ſeveral years before 1759[q].

7. The appearance of *this* ſhrub is between that of Privet and Alaternus. Stem ſtraight; bark greeniſh aſh-colour ſpotted with white; the upper part and particularly the ends of the branches covered with long hairs. Leaves like thoſe of Privet, of a ſhining pale green, but in form approaching thoſe of Alaternus; ſmooth, but along the edges and on the middle nerve underneath having ſlender greeniſh hairs. The flowers come forth among the leaves in ſmall bunches, as in Privet: corolla ſcarcely tubular, cut almoſt to the bottom into five (ſometimes four) equal ſegments, white or herbaceous, having the ſmell of Elder flowers; calyx ſhort, cut into the ſame number of ſegments with the corolla, theſe are acuminate, of a greeniſh colour, and extend almoſt to the bottom. Stamens five (or four, when the diviſions of the calyx and corolla are four.) The flowers, when they decay, turn of a reddiſh brown, like the Privet.—Cultivated in the Eltham garden about 1728, from ſeeds that came from Patagonia in South America[r].

Linnæus ſaw that this plant is nearly allied to the genus *Cordia*. He makes the eſſence of *Patagonula* to conſiſt in the largeneſs of the fructiferous calyx. The corolla alſo having little or no tube is wheel-ſhaped: and the fruit is a capſule. With the ſeeds we are not yet well acquainted. I have followed the ſkilful author of *Hortus Kewenſis*, in reducing it to this genus. It flowers moſt part of the ſummer.

8. Native of the iſland of Tongatabu.

9. Native of New Caledonia[s].

10. Branches round, ſmooth, ſomewhat hairy at the tip. Leaves ſeſſile, unequal, have three, and ſometimes four blunt teeth at the end, the middle ones ſmaller; the upper ſurface is ſhining, and over it are ſcattered ſhining ſcales, from the centre of which ariſe minute white ſolitary appreſſed hairs, it is ſcarcely rugged; and the lower ſurface is even, paler and void of dots. The buds are tomentoſe tubercles. Peduncles from the ſame bud with the leaves, ſolitary, one-flowered, pubeſcent, ſhorter than the leaves. Calyx five-parted; parts lanceolate, broader outwards, acute, hairy. Style ſometimes ſingle, dichotomous; ſometimes two ſtyles, which are bifid and the length of the corolla: ſtigmas acute. Fruit the ſize of Pepper, the calyx not growing to it, four-celled: in each cell ſeveral ſeeds. There is a tranſverſe furrow in the middle of the partition.

It has the habit of Cordia with ſcaly leaves, and a ſtyle commonly dichotomous; but it recedes, as is apparent, in ſome particulars[t].

11. Native of Jamaica and other iſlands of the Weſt Indies.

12. Native of Jamaica[u].]

PROPAGATION AND CULTURE.

Theſe plants, being natives of hot countries, are too tender to live through the winter in this country, unleſs they are preſerved in a ſtove: they are all propagated by ſeeds, which muſt be procured from the countries of their natural growth; theſe ſeeds muſt be ſown in ſmall pots, which muſt be plunged into a good hot-bed of tanners bark in the ſpring; and if the ſeeds are freſh and good, the plants will begin to appear in ſix or eight weeks after. Theſe muſt be brought forward in the hot-bed, by being treated as other tender exotic plants, obſerving frequently to water them in ſummer; and in july, if the plants have made much advance, they ſhould be gradually hardened, otherwiſe they will grow ſo weak as not to be eaſily preſerved through the winter. As theſe plants obtain ſtrength, they will become more hardy; but during the two firſt winters, it will be proper to plunge them into the tan-bed in the ſtove; but when they begin to have woody ſtems, they may be placed on ſhelves, in a dry ſtove; where, if they are kept in a moderate degree of heat, they may be preſerved very well (eſpecially the third ſort) which is ſomewhat hardier than the others. This may alſo be placed abroad in a warm ſituation, in the beginning of july, where the plants may remain till the middle of ſeptember, provided the ſeaſon continue warm, otherwiſe they muſt be removed into the ſtove ſooner.

Leaves three-lobed, lobes acuminate, serrate, middle one longer.]

DESCRIPTIONS, *&c.*

1. Root perennial. Stems many, stiff, angular, upwards of three feet high. Leaves opposite; leaflets very narrow and entire. Branches opposite. Peduncles long, slender, one-flowered. Ray yellow; disk dark purple.

[Leaves often in whorls. Calyx like that of *Bidens*, with a spreading calycle [a].

Being a showy plant, growing very tall, and continuing long in flower, it is a great ornament to the shrubbery. The florets, though yellow, are used in North America to dye cloth red [b].

Native of North America. Cultivated 1759, by Mr. Miller [c]. It flowers from july to september.

2. The plant is altogether that of *Bidens frondosa*, but it has the flowers of *C. verticillata*, with a large eight-petalled, striated, oval ray.—Native of Virginia. Annual [d].

3. Stem three or four feet high, four-cornered, smoothish, the opposite sides channelled. Leaves opposite. Leaflets five, seldom three, ovate, undivided, smooth, equal, even, the three outer often confluent, almost decurrent by the outer side, quite entire at the tip. Petioles channelled, connected on both sides by villose hairs. Flowers terminating, alternate, two or three, on longish peduncles. Calyx five-parted, within a smaller five-leaved involucre or outer calyx. Ray of the corolla usually with five white florets, which are ovate, three-toothed at the end, the middle one longest, three-nerved underneath. Disk small, convex, yellow. Seeds with a three-toothed crown, hispid backwards. The disk of seeds becomes pyramidal [e].

The flower has the appearance of *Leucanthemum*. The plant is like the foregoing.—Native of America. Annual [f].

Linneus had it from Miller.

4. Stem quadrangular, simple, jointed. Leaves on the stem opposite, smooth; on the flowering branches alternate, smaller. Flowers terminating, on long peduncles, solitary, with six three-toothed florets in the ray, which however are often wanting. Native of South America [g].]

5. Root perennial. Stems strong, round, smooth, six or seven feet high. Flowers in bunches at the top of the stem, on long peduncles. Ray of the corolla pale yellow; disk dark purple.

[Most of the leaves are ternate, but on the stem they are sometimes almost pinnate. It has the calyx of *Bidens* with a spreading calycle.——Native of North America [h].

6. This is a climber. The florets of the margin are all neuter, and rise immediately from the bottom of the inward scales. The seeds are bidented. Native of the hills in Jamaica [i], and of the island of Santa Cruz [k].

7. Root small, fibrous, annual with us. Stem climbing, weak, five feet high, branching, leafy,

[a] Linn. spec. [b] Curtis. [c] Hort. kew.
[d] Linn. spec. [e] Linn. amoen. [f] Linn. spec.
[g] Plumier. [h] Linn. spec. [i] Browne.
[k] Linn. spec.

ſtriated, ſmooth, ſquare at the baſe, roundiſh above. Leaves oppoſite, petioled, acute, veiny, ſoft, ſlightly downy, bright green, paler beneath: petioles channelled hairy. Stipules none. Peduncles three to five, from the axils of the top leaves, terminating, erect, round, ſtriated, hairy, ſingle-flowered. There are ſometimes two or three lanceolate, entire bractes, at the baſe of the peduncles. Calyx nearly cylindrical, with a few of the outermoſt leaves ſpreading. Florets all gold-coloured; thoſe of the ray with about four teeth and veined; thoſe of the diſk five-cleft. Anthers half excluded, brown. Stigmas downy above, obtuſe. Germ linear, ciliate on the edges. Scales of the receptacle lanceolate, about as long as the florets of the diſk [l].

Linneus ſays it is a large plant, having the calyx of *Bidens*, with a ſpreading calycle. Seeds awned.

Native of Jamaica, in the inland woody parts [m], and probably of Antigua [n].

This cannot be the ſecond Verbeſina of Browne, which he calls upright, and of which he ſays the leaves are entire.—It is named by that author (in his manuſcripts) C. viminea.

Introduced by the Marchioneſs of Rockingham [o].

8. *Stem* eight feet in height, herbaceous, erect. *Leaves* oppoſite, petiolate, three-nerved. *Flowers* at the ends often three, peduncled, very ſmall, like thoſe of *Rudbeckia*. Calyx conſiſting of ſixteen leaflets, broad-ſubulate, recurved, the length of the diſk. Ray of the corolla neuter, yellow, three-toothed, longer than the diſk. *Fruit* naked, almoſt globular, berried; the ſeed within ſomewhat four-cornered, dark-coloured. The fruit is exactly the form of a Blackberry.

Native of Surinam. Dalberg [p].

9. Stem from nine inches to a foot in height, upright, covered with a ſoft down. Lower leaves round or ovate, on petioles an inch in length: upper leaves ternate; the middle leaflet much larger. Flowers golden-coloured, with about eight florets in the ray.

Native of Virginia, whence it was firſt ſent by Baniſter [q].

10. Stems ſeveral, decumbent at bottom, and thence riſing obliquely, a foot and half or two feet in length. At each joint a pair of oblong leaves, with other ſmaller ones. Peduncles round, ſmooth. Florets in the ray eight or nine, broad, with four deep large teeth at the end. Calyx double, each conſiſting of eight or nine leaflets, the outer thick and ſpreading, the inner larger, upright and preſſed cloſe to the flower, tranſparent and of a pale ochre colour. The ſeeds while young are ſhort, flat and compreſſed, but afterwards take the form of a ſmall hemiſpheric beetle or bug; they are of a browniſh purple colour, and have a third awn between the two outer ones.—This plant laſts two or three years, and flowered firſt in the Eltham garden 1725, from ſeeds ſent from Carolina [r].

The ſeeds were received from Cateſby in 1724, and ſown in many gardens near London [s].

11. This is certainly a mere variety of *Bidens cernua* (which ſee) differing in nothing but the radiated flowers, and being frequently found bearing both ſorts from one root, as is well expreſſed in *Vl. dan. t.* 841.—*Coreopſis Bidens* in the Linnean Herbarium agrees with our ſpecimens [t].

12. Root woody, perennial. Stems ſeveral, annual, erect, angular, filled with white pith, winged, from five to ten feet high, ſimple, having only very ſhort ſubdiviſions at the top into roundiſh villoſe peduncles. Leaves rugged on both ſides, of a dirty green colour; the lower ones three or four together or two oppoſite, the reſt alternate, decurrent. Calyx ſpreading very much, or even wholly turned back, conſiſting of a double row of oblong, ſharp, ſmoothiſh leaflets, ſhorter than the florets of the diſk, and uncertain in their number. Florets in the ray from four to eight, yellow; border ſlightly toothed, very concave with the ſides rolled in. Anthers blackiſh. The flowers have but little ſcent, and coming late in october or november, ſeldom perfect their ſeeds with us [u].

Native of Virginia and Canada.] Mr. Miller ſays, in North America every where.—[Cultivated 1759, by Mr. Miller [x].

13. Native of North America. Introduced 1785, by Charles Earl of Tankerville. It flowers in auguſt and ſeptember, and is perennial.

14. Native of Carolina. Introduced 1786, by Mr. Adam Robſon. It flowers from auguſt to october, and is perennial.

15. Native of Carolina and Florida. Cultivated 1778, by John Fothergill, M. D. It flowers in june, and is perennial.

16. Native of North America. *Mr. John Cree.* Introduced 1765. It flowers in ſeptember and october, and is perennial [y].

Probably the ſame with alternifolia of Linneus; and alternifolia hort. kew. a different plant.]

17. Root annual. Stems upright, four feet high. Leaves acuminate, from three to four inches long, three quarters of an inch broad in the middle, deep green on their upper ſurface, and pale on their lower, on ſhort petioles. At all the upper joints of the ſtem two long ſlender peduncles come out, one on each ſide, having two or three pairs of ſmall leaves on them, and terminated by one flower, having ſeven oval entire florets in the ray, and many dark-coloured ones in the diſk. It flowers in auguſt, and if the autumn prove favourable ripens its ſeeds in october.

Native of South Carolina, whence the ſeeds were ſent by Dr. Dale to Mr. Miller.

[18. Stem herbaceous, a foot and half high, erect, four-cornered, grooved, ariſing from a ſimple, perpendicular, fuſiform, white, fleſhy root. Leaves quinate, lanceolate. Flowers entirely ſaffron-coloured, few together on terminating peduncles. Florets in the ray fix, ovate, quite entire. Down of the ſeeds three-horned, branched with inverted briſtles. Calyx erect, many-leaved.

19. Stem herbaceous, two feet high, erect, four-cornered, four-grooved. Flowers entirely yellow, in a ſparſe, terminating panicle. Six florets in the ray. Down two-horned, branched. Receptacle flatiſh, naked.—Both theſe are natives of China, near Canton [z].

20. Root annual. Stem round, upright, a fathom in height, branched, covered with a ſhort glutinous nap. Leaves cordate, the lobes broad; they are glutinoſe, ſtrong-ſmelling, a little longer than the petioles, which are connate at the baſe, all oppoſite except the floral leaves, which are ſeſſile and lanceolate. Flowers corymbed. Calyx ovate, conſiſting of ſixteen ovate-acute, keeled leaflets, in a double row, the eight outer ones blackiſh-green, hirſute and glutinoſe. Corolla yellow: florets of the ray eight, border ovate, oblong, three-nerved, ſhortly emarginate; germ white, ſlightly four-cornered, oblong, barren. Germ of the hermaphrodite florets in the diſk ovate-four-cornered, the lateral angles compreſſed, the inner ones narrower; it has two briſtles at the top. Chaffs of the receptacle ovate-acute, keeled. Seeds obovate, obſcurely three-ſided, compreſſed, narrower at the baſe, with two white, capillary, upright toothlets.——Native of Mexico.

It flowered in the royal garden at Madrid in october and november, before the year 1791. This plant is one of the connecting links between this genus and Helianthus *.]

PROPAGATION AND CULTURE.

1. 2. 5. 9. 12. 13 to 16. Theſe hardy ſorts may be propagated in plenty, by parting the roots; the beſt time for which is in autumn when the ſtalks begin to decay.—The firſt and fifth require a

[l] Smith. [m] Sloane. [n] Smith. [o] Ibid. [p] Linn. ſuppl. [q] Moriſon. [r] Dillenius. [s] Mart. cent. [t] Woodw. Mſs.

[u] Jacquin. [x] Hort. kew. [y] Ibid. [z] Loureiro. * Cavanilles.

light

light loamy earth, and funny expoſure. The twelfth will thrive in almoſt every ſoil and ſituation.

10. The ſeeds of this muſt be ſown upon a gentle hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be ſet each in a ſeparate ſmall pot, and plunged into a freſh hot-bed to bring them forward. In june they ſhould be inured by degrees to the open air, and afterwards ſome of them may be ſhaken out of the pots, and planted in a warm border; where, if the ſeaſon be good, they will flower in the middle of july, and ripen their ſeeds in the beginning of ſeptember.

17. This is propagated by ſeeds, which ſhould be ſown on a warm border in autumn, and the plants will come up the following ſpring; for if the ſeeds are ſown in the ſpring, the plants ſeldom riſe till the year after. When the plants are fit to remove, they ſhould be carefully taken up, and either planted where they are deſigned to remain, or into a nurſery-bed, at four inches diſtance, to get ſtrength, obſerving to ſhade them from the ſun till they have taken freſh root: after which, thoſe which are planted out for good, will require no other treatment but to keep them clean from weeds; and as they advance in height, they ſhould be ſupported by ſticks, otherwiſe the ſtrong winds in autumn often break them; and thoſe which were placed in a nurſery-bed, when they have obtained proper ſtrength, ſhould be taken up and tranſplanted with balls of earth to their roots, where they are deſigned to ſtand for flowering.

As theſe plants continue to produce flowers till the froſt puts a ſtop to them, they merit a place in every curious garden, eſpecially thoſe which do not ramble and ſpread too much. The firſt is ſeldom preſerved, but in botanic gardens for the ſake of variety.

DESCRIPTIONS, *&c.*

1. Root annual, ſmall. Stem a foot or a foot and half in height, ſmooth, branched. Root-leaves larger, doubly pinnate, pinnules broad, gaſhed on every ſide, ſerrate and even half-two-lobed: upper leaves very finely divided, alſo doubly pinnate; the pinnules linear, ſlender, divided into two or three ſegments. Univerſal involucre one-leafed or none; the three leaflets of the partial involucre ſmall, filiform [a].

Petals white, or reddiſh. It flowers in june and july, in corn fields, by road ſides, and on dunghills. The ſeeds ripen in july and auguſt.

The leaves have a ſtrong diſagreeable ſcent. The ſeeds are grateful to the taſte, and incruſted with ſugar are ſold by the confectioners. The Edinburgh college uſe them as correctors in the bitter infuſion and the preparations of Senna, nothing ſo effectually covering the diſagreeable taſte of that medicine. They have been conſidered as ſuſpicious, if not deleterious; but I have known ſix drams of them taken at once, without any remarkable effect [b]. Native of the South of Europe, China, and Cochinchina.

This plant, though found wild in Eſſex, where it has been long cultivated, about Ipſwich, and in a few other places, is not a native of this country.

2. The ſcent of this is much ſtronger than that of the common ſort. Root annual. Stem angular. Umbel uſually ſimple, very ſeldom compound. Univerſal involucre one-leafed: partial none. Petals not rayed. Anthers purpliſh. Germs twin at bottom [c].

According to Loureiro, the ſtem is almoſt upright, round, pale, ten inches high, with many weak diffuſed branches. Leaves decompound, the ſegments linear, ſlender, ſmooth. Umbels compound, ſmall, concave; both involucres many-cleft, ſubulate. Fruit twin, green tinged with brown, ſtronger both in ſmell and taſte than the common ſort.

Native of the South of Europe, China, and Cochinchina.—Cultivated 1739, by Mr. Miller [d].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſowing their ſeeds in the autumn, in an open ſituation, on a bed of good freſh earth; and when the plants are come up, they ſhould be hoed out to about four inches diſtance every way, clearing them from weeds; by which management theſe plants will grow ſtrong, and produce a greater quantity of good ſeeds. The firſt ſort was formerly cultivated in the gardens as a ſalad herb, and in the Eaſt Indies is ſtill much cultivated; for the plant is of great uſe in moſt of their compound diſhes, as a culinary herb, and the ſeeds are alſo much eſteemed for the like purpoſes; but in Europe neither of them are now much uſed.

The ſecond ſort will riſe eaſily from ſeeds, if they are ſown in the autumn; but thoſe which are ſown

[a] Krocker, chiefly from Haller. [b] Withering. [c] Linn. ſpec. [d] Hort. kew.

in the ſpring rarely ſucceed, or at leaſt do not come up till the following ſpring.

[For the field culture of Coriander, ſee Carum or Caraway.

The produce of Coriander is from ten to fourteen hundred weight on an acre, and the price varies from 16s. to 42s. a common price is 24s. for a hundred weight.

If great care be not uſed, the largeſt and beſt part of the ſeed will be loſt. To prevent this, women and children are employed to cut it, plant by plant, and to put it immediately into cloths, in which it is carried to ſome convenient part of the field, and there threſhed upon a ſail-cloth. A few ſtrokes of the flail get the ſeeds clean out, and the threſhers are ready for another bundle in a few minutes.

There is a ready ſale for Coriander ſeed with the diſtillers, druggiſts and confectioners. The former purchaſe very large quantities[a].]

CORIARIA. (*Has its name, from its uſe in tanning hides.*)

Forſt. flor. auſtr. n. 377.

Procumbent diffuſed; leaves cordate-ovate acuminate quite entire five-nerved ſubpetiolate; racemes axillary elongated nodding.]

DESCRIPTIONS, *&c.*

1. This ſhrub ſeldom grows more than three or four feet high. It creeps at the root, and ſends forth many ſtems.

[In the male plant, the flower-buds are often in pairs from the ſcar of the fallen leaves. Male aments cylindric, oppoſite, in pairs (one from each bud, leafleſs; pairs from one to five, below the polygamous aments. Flowers ſeparated by fleſhy, concave ſcales. Hermaphrodite buds alſo ſolitary or in pairs, above the former, in ſeveral pairs. Aments like the others, except that they have frequently a pair of leaves at the baſe; the flowers are ſeparated by ſimilar ſcales, and have ſome males mixed with the hermaphrodites. The other buds, which occupy the ends of the branches, have male flowers only, in leafleſs aments.

In the female plant, very many flower-buds are placed along the branches, oppoſite by pairs. Aments long, peduncled, more leafy, having from one to four leaves, the outmoſt gradually larger. Raceme looſer, few-flowered; the ſcales ſeparating the flowers are narrower and more acuminate[c].

This plant therefore, according to Gouan, is polygamous, having hermaphrodite and male flowers in the firſt, female and male in the ſecond deſcribed above; hermaphrodite and male on a third. Medicus deſcribes a plant with hermaphrodite flowers only.

It is a native not only of the South of France, but alſo of Spain, and the county of Nice.—Cultivated 1629, by Parkinſon. It flowers from may to auguſt[d].]

The plant with male flowers only was common in England, till that which bears hermaphrodite flowers was raiſed in the Chelſea garden from ſeeds ſent out of Italy, which produced great quantities of ſeeds, that vegetated.

[It is conſiderably aſtringent, and is uſed not only in tanning leather, but in dyeing black colours[e].]

This ſhrub ſending up many ſtems forms a thicket, and therefore is uſeful to fill up vacancies in plantations of ſhrubs; but it is improper for ſmall gardens, becauſe it takes up too much room, and there is no great beauty in the flowers.

[2. Leaves ovate-oblong, ſubcordate, ſubſeſſile. Flowers hermaphrodite.

Native of Chili.

3. Native of New Zealand.]

PROPAGATION AND CULTURE.

1. It may be propagated plentifully from the ſuckers, which are produced from the creeping roots in great abundance; theſe ſhould be taken off in march, and planted into a nurſery to form good roots, where they may continue one or two years, and then muſt be removed to the places where they are to remain.

This plant delights in a loamy ſoil, which is not too ſtiff, and ſhould be placed where it may have ſhelter from the north and eaſt winds; where it will endure the cold of our ordinary winters very well, and will flower better than if it is preſerved in pots and ſheltered in the winter, as hath been by ſome practiſed.

DESCRIPTION, *&c.*

This plant ſeldom grows above ſix inches high, and ſpreads near the ſurface of the ground like Heath. In june, when it is full of flowers, it makes a very pretty appearance.

[The ſtem is red. The leaves are alternate, linear, thickiſh, ſpreading. The flowers are in ſpikes[a], purpliſh or blueiſh. Stigma ſimple, not five-cleft[b]. Native of the South of France. Cultivated in 1739[c].

Linneus ſays the root is annual, in the hortus kewenſis it is marked as biennial, and according to Villars it is perennial.]

There are two varieties of this plant, one with a red, and the other with a white flower.

PROPAGATION AND CULTURE.

This may be propagated by ſowing the ſeeds in the ſpring, on a bed of freſh earth; and when the plants are about an inch high, they ſhould be tranſplanted, ſome of them into pots filled with freſh light earth, that they may be ſheltered in winter; and the others into a warm border, where they will endure the cold of our ordinary winters very well, but in ſevere froſt they are generally deſtroyed; for which reaſon, it will be proper to have ſome plants in pots, which may be put under a common hot-bed frame in winter, where they may be covered in froſty weather; but when it is mild, they ſhould have a great ſhare of free air: theſe plants ſometimes produce ripe ſeeds in England, but as they do not conſtantly perfect their ſeeds, it will be proper to increaſe them from ſlips and cuttings, which will take root, if planted about the end of auguſt on a very gentle hot-bed, and ſhaded from the ſun and duly watered.

CORIS. See *Euphraſia* and *Hypericum.*

CORISPERMUM. (*From κόρις, a bug or tick, and σπερμα, ſeed.*)

Rhagroſtis fol. arundinaceis. *Buxb. cent.* 3. *t.* 56.
Spikes axillary ſquarroſe, leaves lanceolate-acuminate pungent nerved.

DESCRIPTIONS, *&c.*

1. [Root annual. Stem varying from a long ſpan to a cubit in height, upright in dry ſoils, but in moiſt ones ſpreading and diffuſed; the branches aſcending; the lower ones oppoſite, in length frequently reaching above the middle of the ſtem; the others alternate, ſtriated with green and red like the ſtem; having pale grooves between. Leaves alternate, ſoft, linear-acute, with a very fine needle's point. From each axil a branchlet terminated by a ſpike of flowers. Spikes more or leſs crowded or elongated, with alternate imbricating bractes, ovate or lanceolate-acuminate, membranaceous with a white or red edge, one-flowered, and increaſing with the fruit. From each bracte proceeds a ſingle flower, which has no corolla, but only a white pellucid little membrane, oppoſite to the bracte, involving the genitals, and as the fruit grows decaying together with the filaments. Stamens in moſt of the flowers three, between the germ and the little membrane, the middle one longer and ſtouter; the ſide ones frequently withering, or wanting. In other ſpikes, often on the ſame plant, the flowers have five ſtamens. The anthers project beyond the corolla, are twin and yellow. Germ very ſmall, ovate; with two very ſmall ſtyles; quickly growing into an oval flat ſeed, a little convex on the outſide, with a ſharp edge round it, and a ſmall inciſure at the place of the ſtyles. The ſeeds are ripening at the baſe of the ſpike, whilſt the flowers are coming out at the top. The ſeed contains a little ſpire, having the radicle at one end, and at the other divided into two leaflets; whence its natural affinity to Salſola and Polycnemum.

It varies much in different parts of the Ruſſian empire; being ſmooth and very ſucculent, becoming red in winter, a foot and half high and more, with very broad bractes, long imbricate ſpikes, and very large ſeeds; or in dry ſoils very ſlender, hoary, with ſmall ſpikes, bractes and ſeeds, or about the lake Baikal, not tall, but very robuſt, with ſhort ſpikes like ſtrobiles, and wide bractes, the whole plant red in winter; or in the Caſpian deſert, a cubit high or more, branching very much, with ſpikes above a ſpan long, and remote bractes.

It is common all over the Ruſſian empire in ſandy ſoils, eſpecially on the banks of lakes and rivers, and in low moiſt places: where it affords paſture for the camels, with the next ſpecies, and the various ſorts of Atriplex and Salſola[d]. It is alſo found in the South of France. It was cultivated by Mr. Miller in 1739[e].

2. This varies in ſize like the foregoing, but not in the proportion of the parts. Root annual. The whole plant dry, more rigid, pubeſcent with a hoary lanugo. Stem and branches round, with neat whitiſh ridges. In ſmall plants there are four oppoſite aſcending branches next the root, often longer than the middle ſtem, which is ſometimes hardly a finger's length, and ſimple. In larger plants, which ſometimes exceed a cubit in height, the ſtem is higher than theſe root-branches, and is branched alternately to the very top. The leaves have five rigid, prominent nerves. Spikes ſeſſile, very ſhort and crowded, muricated all round with very ſpreading ſpineſcent bractes. There is a ſeſſile flower to

[d] Pallas. [e] Hort. kew.

each bracte, usually one-stamened, with very fugacious anthers; styles longer; seeds smaller, not margined, mucronate-bifid with the styles.—Native of Russia, but more confined and local[f]. Cultivated by Mr. Miller in 1759[g].

Gmelin is of opinion that these are not specifically different: but neither he nor Linneus seem to have been acquainted with the second sort. Linneus probably made out his first species from the last variety mentioned above, and his second from the first, second, and third varieties[h].]

PROPAGATION AND CULTURE.

These plants having little beauty are seldom cultivated, except in botanic gardens. The ground will be plentifully stocked with the first sort if it be permitted to scatter its seeds.

The second sort will not grow but in marshy places, it will soon extend over the surface of standing water, when once it is established.

DESCRIPTIONS, &c.

1. Root annual, fibrous, branched. Culms numerous, ascending, jointed, round, smooth, striated, branched, leafy, dark purple at the joints. Leaves sheathing, striated; sheath inflated, shorter than the internodes, spreading, pointed. Stipule solitary, in the bosom of the leaf, entire. Flowers several, arising from the sheaths of the upper leaves. Involucre slender, incurved, horny, cylindrical, striated, rough when drawn backwards through the hand, gradually swelling upwards, and enlarged at the top into an hemispherical cup, neatly notched in its margin, purplish, durable. Flowers in a little head or spike, projecting somewhat beyond the involucre, green often tipped with purple. Calyx and corolla striated, obtuse. Filaments projecting very far. Styles connected at the base, spreading in the upper part, twisted, the length of the filament. Stigmas acute. Seed small. Of all grasses, this is perhaps the most singular, as well as the most uncommon[i].

Native of the vales about Smyrna, whence it was sent to England by Sherard, when he was consul at Smyrna: and afterwards to Linneus by Hasselquist.

Introduced at Kew in 1788, by John Sibthorp, M. D.[k] But it has constantly been cultivated in the Chelsea garden since the time of Rand[l].

2. This very much resembles our common Fox-tail grass (*Alopecurus pratensis.*) Culms ascending, even. Leaves even. Spike terminating, ovate, loose, with the florets on very short pedicels. Glume of the calyx two-valved, equal, ovate. Glume of the corolla one-valved, the length of the calyx, to which is opposed a spreading awn, twice the length of the flower. Sheath of the upper leaf ventricose, as in *Phalaris*. The singular mark of this species is a hood in form of a pitcher, quite entire, of the same consistence with the leaf, surrounding the base of the spike like a common calyx. Observed in Italy, by Arduini[m].

DESCRIPTIONS, *&c.*

1. This ſort ſeldom riſes above ſeven or eight feet high, but is generally well furniſhed with large leaves. It does not flower here very plentifully, nor does it produce berries in England, though it is very hardy.

There is a variety of it with a roſe-coloured involucre, which was found wild in Virginia by Baniſter, and afterwards by Cateſby. They are great ornaments to the woods in America, by their early flowering in the ſpring before the leaves appear, and by their berries hanging on all the winter.

[Cateſby ſays, that the bloſſoms break forth in the beginning of march, being at firſt not ſo wide as a ſixpence, but increaſing gradually to the breadth of a man's hand, being not of their full bigneſs till about ſix weeks after they begin to open. (This is the involucre.) It is greeniſh white, ſometimes roſe-coloured, and each of the four leaflets has a deep indenture at the end. The berries are from two to ſix in a cluſter, cloſely joined, on peduncles an inch long; they are red, oval, and the ſize of large haws: being bitter, they are little coveted by birds, except in time of dearth. The wood is white, has a cloſe grain, and is very hard like that of Box.]

It is common in our nurſeries, where it is known by the name of Virginia Dogwood, [and was cultivated in 1739, by Mr. Miller[a]. Cateſby ſays, that Fairchild had it in his garden. It flowers in april and may.

2. In its wild ſtate it is a ſhrub, four or five feet in height; but cultivated, it advances into a tree, twenty feet high. Shoots aſh-coloured and pubeſcent. Leaves in pairs, ovate-lanceolate, ſubhirſute. The flowers come out very early in the ſpring, before the leaves. Leaflets of the involucre lanceolate, often reflected, permanent. Peduncles one-flowered, ſomewhat villoſe, from twelve or fifteen to thirty in an umbel. Corolla yellow, ſpreading, and at length reflected, longer than the ſtamens. Top of the ſtyle bent in and papilloſe. Fruit oblong, of a high ſhining ſcarlet colour, the ſize and form of a ſmall Olive or Acorn. The geſtation endures about five months, and the greater part of the flowers drop without fruit[b].]

The Cornelian Cherry is very common in plantations of ſhrubs. If the ſeaſon be mild, the flowers will come out the beginning of february; and though there be no great beauty in them, yet they are produced in plenty at a ſeaſon when few other flowers appear. Formerly it was cultivated for the fruit, which was uſed to make tarts, and a rob de Cornis was kept in the ſhops.

[Cornel, ſays Evelyn, grows with us of good bulk and ſtature, and is exceedingly commended for its durableneſs in wheel-work, pins and wedges, in which it laſts like the hardeſt iron.

Native of France, Ruſſia, Germany, Switzerland, Auſtria, Carniola, Piedmont, the Milaneſe.—Cultivated in 1596, by Gerarde[c].

3. *Stem* erect, ſix feet in height: branches oppoſite, ſtriated, aſh-coloured, ſmooth. *Leaves* at the ends of the branches, oppoſite, petioled, ovate, acuminate, entire at the baſe, nerved, pale underneath, ſmooth, two inches broad and three long. *Petiole* angular, ſmooth. *Flowers* terminating, umbelled, white. *Umbel* decompound, with from three to five rays, much ſpreading. *Peduncles* and *pedicels* half-cylindric, channelled, ſmooth. Leaflets of the *involucre* lanceolate-ſetaceous, deciduous, many times ſhorter than the umbel. *Perianth* four or five-parted, ſmooth; diviſions ovate, acute. *Filaments* ſhorter than the corolla. *Germ* ſuperior; *ſtyle* very ſhort; *ſtigma* three-cornered. *Drupe* ovate, acute, compreſſed, red, ſmooth, the ſize of a ſmall Pea, with the ſtyle permanent. The fleſh thin and ſubacid. The ſtone hard and ſhaped like a lens. The kernel white and hard.—Native of Japan[d]. L'Heritier affirms, that this is a Viburnum.

4. Height from four or five to eight or ten feet. Leaves oppoſite, quite entire but ſometimes with the edge waving, ſtrongly nerved, ſlightly pubeſcent on both ſides, two inches and an half long, one and an half broad: petioles ſmooth, furrowed above, and four lines in length. Peduncles axillary, leafleſs; pedicels ſhort and very cloſe together: forming a five-cleft cyme, again ſubdividing. Small

[a] Hort. kew. [b] Haller and Scopoli. [c] Hort. kew. [d] Thunberg.

deciduous

deciduous bractes at the base *of the peduncles*. Calyx four or five-toothed. Petals greenish white, lanceolate, revolute. A four-lobed ring surrounds the base of the style. Some of the flowers are female. Fruit round, obscurely umbilicate; very dark-purple: the pulp soft and bitter; the stone round, bony, marked obscurely with eight furrows, two-celled, with one plano-convex white seed in each cell [a].

Native of Europe in hedges, especially in a calcareous soil. It flowers in june, and the berries ripen in august.

This common shrub has a variety of names in different parts of our kingdom—as *Female Cornel, Dogberry tree, Hound's-tree, Hound's-berry tree, Prick-wood* from its use in making skewers, *Gaten* or *Gatten-tree, Gater* or *Gatter-tree*.

Our common Dogwood, says Evelyn, is like the Cornel for compactness, and is made use of for cart-timber, and rustick instruments, for mill-cogs, spokes, bobins for bone-lace, and the best of tooth-pickers and butchers skewers. Being hard and even, it is fit also for the turner. In some countries abroad they extract an oil from the berries for lamps, by boiling them in water, and pressing them. Haller observes, that these berries are very bitter and styptic, but not used in medicine.]

Mr. Miller informs us, that the fruit is often brought into our markets, and sold for Buckthorn berries, from which however it may easily be distinguished; there being only one stone in this, whereas the Buckthorn has four stones; the latter also stains paper green, but the juice of the former is purple. Dogwood is called *Virga sanguinea* by old authors, from the young shoots being of a fine red colour. A variety with variegated leaves is to be found in the nurseries, but it is not much esteemed.

5. [This very much resembles the foregoing: differing only in its recurved branches and white berries. Many of the suckers are procumbent [c].

Stem woody, putting out many lateral branches near the ground, so that unless it is trained while young, it generally spreads low. The branches during summer are brownish, but in winter change to a fine red. The flowers are produced in large cymes at the extremity of every shoot, towards the end of may, and are white. The fruit also becomes finally white; but unless these shrubs are planted in a stiff ground, they rarely produce much fruit, except in cold wet seasons.

This species was first discovered by Gmelin; and afterwards was found by Messerschmidt near Kamtschatka: it is frequent through all Siberia. Also in North America. The seeds were first sent by Professor Ammann of Petersburgh to England [d].

Native of North America and Siberia.—Cultivated 1759, by Mr. Miller [b].

6. This shrub grows two fathoms in height, with an upright, round, branched, gray stem. Branches opposite, round, spreading, dusky purple; shoots round, with a ring at the joints, almost without spots and dark red, as in *C. sanguinea*, the younger ones more or less pubescent. Leaves acuminate, entire, nerved; the rib and nerves raised beneath, scored above, spreading, flat, three inches long, an inch and half wide. Petioles round on one side, grooved on the other, one fourth of the length of the leaves, villose, reddish. Cymes terminating, peduncled, upright, depressed, scarcely convex, three or four-parted, with an intermediate solitary flower, villose, two inches wide. Flowers pedicelled, horizontal, white, with the disk at first white, but afterwards brown, or dark purple.

The leaves are narrower, and deeper veined than in the foregoing; the flowers grow in smaller cymes; the fruit is smaller, and of a deep blue colour when ripe [e].] The shoots are of a beautiful red colour in winter; and in summer the leaves being large, of a whitish colour on their under side; and the bunches of white flowers growing at the extremity of every branch, this shrub is valuable; and in autumn, when the large bunches of blue berries are ripe, it makes a fine appearance. Native of North America.

[Cultivated 1759, by Mr. Miller [b].

7. Branches subdeterminate, round, glossy, dark purple; with whitish vague dots or lines. Leaves petioled, ovate, acute, quite entire, glossy, marked with lines, pale underneath. Stipules none. Panicles corymbed, flat above, white. Germ obovate. Perianth none. Petals obtuse, sessile, revolute, white. Filaments twice the length of the petals, from spreading erect. Style cylindric, shorter than the corolla. Stigma thickish.—Native of North America [f].

The branches are sometimes red, and sometimes green. It is singular in having the leaves alternate; the twigs also being dichotomous, this shrub has a different appearance from its congeners; the petioles also are longer than in the other species [m]. Cultivated 1760, by Mr. James Gordon. It flowers in september [b].

8. This elegant plant is about six inches high. Stem four-cornered, thinly branched, forked at top. Leaves oval, opposite, smooth, sessile, ribbed with five nerves, the lower ones rounder. The involucre consists of four white leaves resembling petals, in the centre of which are twenty or more small blackish flowers, on short peduncles: the flowers are very small, in a simple umbel: they are succeeded by a cluster of berries which are red when ripe; in each of them is a heart-shaped stone. The berries have a sweet waterish taste, and are acceptable to children: they are supposed by the highlanders to create an appetite, and hence the Erse name, Lus-a-chrasis, *Plant of gluttony* [n].

Native of the north of Europe, and the whole northern tract of the Russian empire from the Baltic to the E. ocean; Cheviot and other hills in the north of England; and in mooriish places by rivulets on the sides of the highland mountains in Scotland.

It is commonly known under the name of *Dwarf Honeysuckle*: and flowers in june.

9. This is only a hand in height, and has the habit of Trientalis or Paris. Stems several, upright, herbaceous, four-cornered, purplish, having some opposite, slightly-clasping leaves at bottom, which wither and fall off. The proper leaves are in whorls from four to six together, solitary at the top of each stalk; they are sessile, roundish or ovate, acuminate, entire, nerved, have scarcely conspicuous hairs scattered over the upper surface, are bright green, paler underneath, spreading, flat, eighteen lines long, and an inch broad. Umbels involucred, terminating, solitary, peduncled, upright, white. Flowers pedicelled, upright, white, with a violet-coloured bottom. Leaflets of the involucre sessile, subcordate, acuminate, entire, marked with lines, white, sometimes red at the tip, horizontal, the two inner ones smaller: the whole involucre is fifteen lines in diameter [o]. (Linnæus says it is longer than in the foregoing sort.)

Pallas suspects it to be only a variety of that, and says that the specimens of C. suecica or herbacea found in Kamtschatka and Bering's island, exactly correspond with the garden specimens of C. canadensis sent from England, and the wild ones from Newfoundland.

Native of Canada, Labrador, and Newfoundland. Introduced 1774, by John Fothergill, M.D. It flowers in august [g].

10. This shrub is the height of a man. Stem upright, branched, gray. Branches opposite, somewhat spreading, round, very thick, green, with brownish warts; twigs like the branches, with rings at the joints, slightly tinged with purple. Suckers

[a] Haller, Scopoli, Pollich, Gærtner. [b] Hort. kew. [c] Linn. mant. [d] Mill. fig. [e] Mill. fig. 70. [f] Linn. suppl. [m] L'Heritier. [n] Hort. kew. [o] Withering & Lightfoot. [g] L'Heritier. [q] Hort. kew.

purple,

purple, with dusky linear spots. Leaves acuminate, entire or nearly so, with semiconcentric nerves, prominent beneath, scored above, the under surface glaucous; they are spreading, flat, four inches in length and breadth; the younger ones tomentose underneath. Petioles an inch long, rounded on one side, channelled on the other, ending in a clasping ring, and spotted like the suckers. Cymes terminating, solitary, peduncled, upright, without any involucre, three or five-parted, pubescent, three inches wide. Flowers pedicelled, upright, white, five lines wide. Peduncles round, tubercled with minute, subulate, loose, caducous bractes, spotted like the suckers and petioles. Pedicels dotted with purple. Some cymes, instead of an involucre, have a two-leaved, opposite, subulate bracte, growing to the peduncle, decurrent and reflex. The proper perianth is acute, upright and permanent. Petals linear-lanceolate, at first spreading, afterwards reflex, sessile, inserted below the crown of the germ. Filaments inserted at the petals, from erect diverging; anthers oblong, two-celled, peltate. Germ silky, whitish: stigma capitate, slightly quadrangular or polygonal. Fruit a berry-form drupe, hollowed at the base, retaining the style, soft, pale blue turning whitish, three lines in diameter: nut roundish, flatted, nerved, a line and half in diameter.

It is distinguished by its orbicular, wrinkled, very green leaves, the cymes bracted at bottom, and its very thick tubercled branches.

It flowers in the summer, frequently twice, but very rarely ripens a few of the fruit in autumn.

It is a native of Pensylvania, and has been long cultivated, but not commonly, in France.

11. This grows to the height of two fathoms. Stems several, upright, brownish. Branches opposite, round, in younger plants strict, in older ones patulous: the twigs, and especially the suckers, stiffish, having rings at the joints, purple, warted closely at the base. Leaves acuminate, entire; midrib purplish at the base; nerves remote, confluent at the tip, prominent beneath, scored above, smooth, bright green scarcely paler beneath, spreading, flat, from two to three inches long, from twelve to fifteen lines broad: petioles erect, only one fixth of the length of the leaf, gibbose on one side, channelled on the other, purple. Cymes terminating, with two branchlets coming out together from the uppermost leaves, peduncled, panicled, five-parted, bracted, from eighteen to twenty-four lines in diameter. Flowers pedicelled, white, with the disk only red, four lines in diameter. Bractes minute, caducous. Perianth four-parted to the very base; segments linear, acute, spreading; it is subpubescent and permanent. Petals inserted below the crown of the germ, sessile, lanceolate, spreading, longer than the calyx. Filaments inserted at the petals, slender, spreading a little, scarcely longer than the petals: anthers oblong, two-celled, peltate, incumbent, pale blue. Germ oblong, truncate, with a nectareous crown: style shorter than the stamens: stigma capitate. Drupe soft, blue, white within, from two to three lines in diameter. Nut ovate, two lines in length.

This has the habit of C. sanguinea and sericea, but recedes far from them, in having the flowers in panicles. These are smaller than in C. paniculata: and the anthers are blue.

It was introduced long since from North America, but is yet scarce. The fruit appears too late to ripen here. The leaves continue green till frost comes on.

12. This shrub is the height of a man. Stems very many, upright, much branched, round, gray. Branches opposite, patulous, like the stems. Twigs and suckers stiffish, having rings at the joints, pale purple, warted. Leaves acuminate, almost entire; the nerves very lax, prominent beneath, scored above; bright green, beneath glaucous, spreading, from two to three inches long, from fifteen to eighteen lines broad: the upper ones, whilst young, reddish. Petioles one third or one fourth only of the length of the leaves, round on one side, channelled on the other, when young scarcely ending in a ring, purplish. Thyrses or panicles terminating, with two branchlets coming out together from the uppermost leaves, solitary, peduncled, upright, without any involucre, three inches wide. Peduncles round, purplish when bearing fruit. Flowers pedicelled, upright, white, three lines in diameter. Perianth four-parted, pubescent, permanent; the teeth very small, narrow and sharp. Petals five, inserted below the crown of the germ, narrow-lanceolate, acute, spreading, afterwards turned back, larger than the calyx. Filaments inserted at the petals, setaceous, diverging, the length of the corolla: anthers oblong, two-celled, peltate. Germ globular, truncate, pubescent, with a nectareous crown, style scarcely shorter than the stamens: stigma capitate, depressed. Drupe retaining the style, scarcely excavated at the base, white, three lines in diameter. Nut roundish, marked with lines.

It is distinct from all the other sorts in having the cymes elongated into a thyrse or panicle. It is handsome, and very full of flowers, which come out in the spring, or early in the summer; in autumn it is loaded with fruit during several months[1].

Native of North America. This and the foregoing sort were cultivated by Mr. Miller in 1758[2].

These American sorts are equally hardy with our common Dogwood, grow as tall, and make a much better appearance.

[Most species of Cornus are Shrubs, some of which become small trees; few are herbaceous. In the latter, the uppermost leaves are in whorls; in the former they are opposite except in the seventh, which has them alternate. The flowers are involucred or not, in umbels or cymes; hence Monsr. L'Heritier has made two divisions of this genus: the first comprehending the *involucred umbelled* species—1. florida. 2. mascula. 8. suecica. 9. canadensis: the second, those which have naked *cymes*; that is, all the rest. The cymes are either depressed, or elongated into a sort of thyrse. The flowers are white, with some sweetness. The fruit is red in C. suecica, canadensis, florida and mascula; white in C. paniculata and alba; blue in C. sericea, circinata and stricta; blackish purple or brown in C. sanguinea and alternifolia. The wood has a particular smell, and in most of the species is hard and tough, particularly in the second, of which the modern Indians make their arrows, as the ancients did their spears[3].

——" bona bello
" Cornus." *Virgil.*]

PROPAGATION AND CULTURE.

All the sorts of Dogwood may be propagated by their seeds, which, if sown in autumn soon after they are ripe, will most of them come up the following spring; but if the seeds are not sown in autumn, they will lie a year in the ground before the plants will appear, and when the year proves dry, they will sometimes remain two years in the ground: therefore the place should not be disturbed where these seeds are sown, under two years, if the plants should not come up sooner. When the plants are come up, they should be duly watered in dry weather, and kept clean from weeds; and the autumn following they may be removed, and planted in beds in the nursery, where they may remain two years, by which time they will be fit to transplant where they are to remain. The best season for this is the autumn. They are also propagated by suckers, and laying down the branches. Most of the sorts produce plenty of suckers, (especially when they are planted on a moist light soil,) which may be taken off from the old plants in autumn, and planted into a nursery for a year or two, and then may be transplanted into the places where they are to remain; but those plants which are propagated by suckers,

[1] L'Heritier. [2] Hort. kew. [3] L'Heritier.

rarely have ſo good roots as thoſe which are propagated by layers; and being much more inclinable to ſhoot out ſuckers, they are not near ſo valuable as plants raiſed from layers.

[Some of the ſcarcer ſorts from America are ſometimes engraſted into the fourth or fifth.]

8. The eighth ſort is very difficult to preſerve in gardens; the only method is, to remove the plants from the places of their natural growth, with good balls of earth to their roots, and plant them in a moiſt ſhady ſituation, where they are not annoyed by the roots of other plants. In ſuch a ſituation they may be preſerved two or three years, but it rarely happens that they will continue much longer.

Agnanthus viburni folio. *Vaill. act. par.* 1722. 273.

Leaves oppoſite, ovate, flowers in terminating corymbs.

[2. Cornutia quinata.

Lour. cochinch. 387.

Leaves quinate, lanceolate-ovate, flowers in racemes.]

DESCRIPTIONS, &c.

1. It grows to the height of ten or twelve feet. The branches are four-cornered, and grow ſtraggling. Leaves oppoſite, ovate, hoary, on very ſhort petioles, acuminate, deciduous. The petiole in falling is broken off a line diſtant from the branch, and remains a hard, truncate, blunt, perennial proceſs, ſupporting the branches that come out from the axils. Flowers in corymbs at the ends of the branches[n]: they are of a fine blue colour, uſually appear in autumn, and ſometimes remain in beauty two months and more.

This plant was firſt diſcovered by Plumier in America. It is found in plenty in ſeveral of the iſlands in the Weſt Indies, as alſo at Campeachy and La Vera Cruz, from both of which places ſeeds were ſent to Mr. Miller, firſt by Dr. Houſtoun, and afterwards by Mr. Robert Millar.

[2. This is a middle-ſized tree, with ſpreading, round branches. Leaves acuminate, quite entire, ſmooth, on a long common petiole. Flowers greeniſh yellow. Corolla ſomewhat funnel-ſhaped; the upper lip trifid, the lower bifid and ſhorter. Native of China, in the woods near Canton[x].]

PROPAGATION AND CULTURE.

1. It is propagated by ſeeds, which ſhould be ſown early in the ſpring on a hot-bed; and when the plants are come up, they ſhould be tranſplanted each into a ſeparate halfpenny pot, filled with light freſh earth, and plunged into a hot-bed of tanners bark, obſerving to ſhade them until they have taken root; after which they ſhould have freſh air let into the bed, in proportion to the warmth of the ſeaſon, and ſhould be frequently watered, for it naturally grows on ſwampy ſoils. When the plants have filled theſe pots with their roots, they ſhould be ſhifted into others of a larger ſize, and plunged into a hot-bed again, where they ſhould be continued till october, when they muſt be removed into the bark-ſtove, and plunged into the tan, for otherwiſe it will be very difficult to preſerve them through the winter. The ſtove in which theſe plants are placed ſhould be kept to the temperate heat marked on Mr. Fowler's thermometers, which will agree better with them than a hotter ſtove. The third year from ſeeds theſe plants will flower, when they make a fine appearance in the ſtove, but they never perfect their ſeeds in England.

Theſe may alſo be propagated by cuttings, which, if planted into pots filled with earth, and plunged into a bark-bed, obſerving to ſhade and water them, will take root, and muſt be afterwards treated as the ſeedling plants.

CORONARIA. See *Agroſtemma*.

CORONILLA. *(Diminutive from corona, a crown; the flowers crowning the branches in a corymb.)*

Lin. gen. n. 853. *Reich.* 956. *Schreb.* 1198. *Gærtn. t.* 155. *Juſſ.* 361. *Tourn.* 419. *Emerus Tourn.* 418. *Mill. dict. Securidaca. Tourn.* 224. *Gærtn. t.* 153. *Mill. dict.*

Claſſ. 17. 4. Diadelphia Decandria.

Nat. order of *Papilionaceæ*, or *Leguminoſæ*.

GENERIC CHARACTER.

CAL. *Umbellule* ſimple:

Perianth one-leafed, very ſhort, compreſſed, bifid, erect: the *three inferior teeth* ſmaller; the *two ſuperior* conjoined; permanent.

COR. papilionaceous.

Standard heart-ſhaped, reflected on all ſides, ſcarce longer than the wings.

Wings ovate, converging at top, gaping at bottom, obtuſe.

Keel compreſſed, acuminate, aſcending, uſually ſhorter than the wings.

STAM. *Filaments* diadelphous (ſingle and nine-cleft), aſcending at almoſt a right angle, the tips widiſh. *Anthers* ſimple, ſmall.

PIST. *Germ* columnar, oblong. *Style* briſtled, aſcending. *Stigma* ſmall, obtuſe.

PER. *Legume* very long, columnar, ſtraight, contracted with an iſthmus between each ſeed; two-valved, one-celled, parting by joints.

SEEDS many.

OBS. *In* Coronilla *of* Tourn. *the Legume is columnar as if jointed: ſeeds longiſh.*

In Securidaca Tourn. *the Legume is compreſſed, with one future, flat, the other narrow. Seeds quadrangular.*

In Emerus Tourn. *the claws of the corolla are longer than the calyx: the Legume narrow and ſubulate: ſeeds cylindric.*

ESSENTIAL CHARACTER.

Cal. two-lipped $\frac{4}{1}$: the upper teeth connate. *Standard* ſcarcely longer than the wings. *Legume* contracted between the ſeeds.

SPECIES.

Shrubby, leaflets nine, emarginate, ſtipules large, roundiſh.

14. Coronilla orientalis. *Levant Coronilla.*

Mill. dict. n. 8.

C. orient. herbacea, fl. magno luteo. *Tournef. cor.* 44.

Herbaceous, legumes numerous radiate thick, jointed, leaflets glaucous underneath.

DESCRIPTIONS, *&c.*

1. [Height from two to ſix feet, (eight or nine in gardens.) Stem not very ſtraight, branched and brachiate: (ſo weak as ſometimes to want ſupport.) Leaflets three or four pairs, gradually larger, almoſt cordate, glaucous, ſmooth. Peduncles umbelled, with from three to five flowers. Calyx broad, four-toothed, longer than the peduncle. Corolla yellow: ſtandard cordate, broad, erect or reflex, marked with lines at the baſe, very remote from the other petals; wings a little ſhorter than the keel, which is wide, with a ſharp beak. Before the claw of the ſtandard is a nectareous ſcale. Legume long, with a claw at the end, and the joints obſcurely diſtinct. Seeds cylindric [a].]

Mr. Miller, who kept this ſpecies diſtinct from the Coronillas, under its old name of *Emerus*, divided it into *greater* and *leſs*. The former, he ſays, is very common in the Engliſh gardens, but the latter in very few, and not known till he procured the ſeeds from Italy. The latter does not riſe to more than half the height, but has larger leaves; the flowers alſo are rather larger, and are on ſhorter peduncles. The leaves, fermented in a vat, in the ſame manner as is practiſed with Indigo, will afford a dye very nearly equal to what is procured from that plant.

Mr. Miller has a third ſort, which he names *Emerus herbacea*, diſcovered by Plumier in the French Weſt India iſlands, and by Houſtoun at La Vera Cruz. Stem herbaceous, upright, three feet high. Leaflets about twenty pairs, blunt, deep green. Flowers ſolitary, axillary, on peduncles two inches long, large, pale yellow. Legumes ſlender, compreſſed, more than ſix inches long, toruloſe, with a border on each ſide.

[The common ſort is a native of France, Germany, Switzerland, Auſtria, Carniola, Savoy.

I found it flowering in April, about Geneva, in many places.

Cultivated in 1596, by Gerarde [b].]

2. This riſes from two to four feet high, with many ſlender woody branches. The flowers ſtand upon pretty long axillary peduncles, in ſmall

[a] Haller & Scopoli. [b] Hort. kew.

bunches;

bunches; they are of a bright yellow colour, and appear for ſix or ſeven months together, but have not produced ſeeds.

[It has branches like Broom; and ſmall leaves, that are ſomewhat fleſhy[c].

Native of the South of France.

Cultivated 1768, by Mr. Miller[a].]

3. This riſes three or four feet high. Flowers on long axillary peduncles *in* cloſe bunches. [*Leaflets* nine or eleven oblong-cordate or wedge-form retuſe, with a ſmall point or none, glaucous, ſomewhat fleſhy. *Stipules* large, cordate, *white*, edged with green. *Flowers* ſmall, deep yellow: claw of the ſtandard ſcarcely receding[b]: wings converging and concealing the keel. Joints of the legume from three to ſeven, elliptic, turgidly lenticular, valveleſs. Seeds ovate-oblong, ſlightly compreſſed, of a red-ferruginous colour[f].

It approaches very near to the *glauca*; but the leaflets are ſmaller, more numerous, and more truly glaucous; the ſtipules, which in the *glauca* are ſmall, narrow and pointed, in the *valentina* are large, almoſt round, and in the young plant ſtrikingly conſpicuous; as the plant comes into flower they drop off: this is not ſo much diſpoſed to flower the year through as the *glauca*, but produces its bloſſoms chiefly in may, june and july: the flowers of the *glauca* ſmell more ſtrongly in the day-time, thoſe of the *valentina* at all times diffuſe a very powerful odour: the latter are more diſpoſed to produce ſeed-veſſels[g]. Linnæus remarks, that early in the ſpring the leaves have the colour of Rue; hence Mr. Curtis names it Rue-leaved Coronilla.

Native of Spain and Italy.

Cultivated 1656, by Mr. John Tradeſcant, jun.[b].]

4. This ſeldom is more than three or four feet high, with a woody branching ſtem. [Leaflets five or ſeven, glaucous, wedge-form, ſeldom obcordate, with a ſmall reflex point. Stipules ſmall, ſublanceolate. Flowers bright yellow, in a roundiſh bunch. Wings gaping widely at bottom, ſo as to diſcover the whole keel[f]. This, ſays Linnæus, has little or no ſmell in the night. During the day the flowers are remarkably fragrant.—Native of the South of France. Cultivated 1739, in the botanic garden at Chelſea[k]. It is diſtinct from C. valentina in having the ſtems not erect, but decumbent. If it has never more than ſeven leaflets, it cannot be the plant figured by Miller in t. 289. f. 1., which indeed has large broad ſtipules, and more reſembles the *valentina*. Flowering from ſeptember to may; indeed almoſt the whole year.

5. Stems erect, little branched, round, ſmooth, about eighteen inches in height, woody at bottom only. Leaves unequally pinnate: leaflets four, five or ſix pairs, glaucous, ſmooth, ovate or retuſe, ending in a point; the end leaflet more obtuſe. Peduncles to three inches in length, round, ſmooth, ſupporting from twenty to twenty-ſix flowers on pedicels three, or blank lines in length. Calyx a line long, yelloviſh: corolla yellow; ſtandard ſeparate, not very large, reflex, ovate, obtuſe: wings ovate, not hooked, a little longer than the keel, which is broad and ſharply beaked. Legumes an inch long, round, deflected, ſcarcely contracted between the ſeeds, terminated by the aſcending ſtyle. The end of the keel is apt to be green, and this with the glaucous hue of the leaves, indicates that a *blue* colour may be produced from theſe yellow flowers by putrefcence[l].

Native of the ſouthern countries of Europe.—Introduced 1776, by Joſeph Nicholas de Jacquin, M. D. It flowers in july[m].

6. Root perennial. Stems ſeveral, woody, branched, two or three inches long, and proſtrate. Hence ſpring, annual, herbaceous, round branches, pale green, alſo proſtrate, leafleſs at top, and ending in a little bunch of flowers. Leaflets five pairs at moſt, obovate, ovate-roundiſh, or orbicular, blunt, quite entire, thick, glaucous on both ſides, veinleſs, ſmall, on very ſhort and ſlender petioles, having the taſte of Rue; end leaflet obcordate: midrib round on one ſide, grooved on the other. Stipules one-leafed, membranaceous, pale, converging ſo as to embrace the baſe of the leaf, bifid at top on the back, often deciduous. Flowers about ſix, yellow, ſweet-ſmelling. Calyx ſmall, green. Wings of the corolla very concave, blunt, twice as long as the keel. Legumes pendulous, ſlightly four-cornered, browny jointed, rugged. Seeds oblong, brown. The whole plant is very ſmooth[n].

Stem, according to Linnæus, the ſtature of *Lotus corniculata*. The loweſt leaflets of the petioles approximating to the ſtem (as in *C. coronata* and *varia*) like ſtipules, ſpreading, expanded in a plane, not leſs than the reſt.

Native of the ſouthern countries of Europe. Cultivated 1683, by Mr. James Sutherland[o].

7. This is a very humble ſhrub, rarely growing more than two feet high, when planted in a good ſoil; but in a dry barren place, not much above one foot. The ſtem is hard and woody, from which the branches are produced on every ſide near the ground, ſo as to form a low buſhy ſhrub. At the joints where the leaves are produced are two ear-ſhaped ſtipules. The flowers are on long ſlender axillary peduncles: they are yellow, and have a ſtrong ſweet ſcent: as the plants always produce great plenty of them, they make a fine appearance during the month of may, which is their ſeaſon for flowering. The ſeeds ripen in auguſt and ſeptember.—The ſilvery colour of this plant is occaſioned by its growing on a poor dry ſoil; and if it is removed into better ground, it will take a glaucous colour; and the contrary.

Native of the iſland of Crete[p].]

8. Root annual, compoſed of a few ſlender fibres, which run pretty deep in the ground. Stems herbaceous, trailing, a foot and half long, dividing into ſeveral branches. Leaves unequally pinnate, compoſed of ſeven or eight pairs of oval, ſmooth, blunt, emarginate leaflets, of a deep green colour; the innermoſt larger, and diminiſhing in ſize to the end. Peduncles axillary, in pairs; ſlender, from four to ſix inches long, with a large cluſter of yellow flowers at the top. [Legumes near four inches long, compreſſed, a little bent like a ſickle, but ſhaped like a broad ſword, terminated by the ſtigma which is ſhort, clawed, but not jointed; in the middle it is pubeſcent, and where the ſeeds lie obſcurely toruloſe; at the ſides it is ſmooth, and has a broad margin; within it is divided into ſeveral cells, but has only two valves; the ſeminal future is divided by a deep furrow: partitions membranaceous, very thin, permanent. Seeds about twelve, of an oblong quadrangular form, compreſſed, ſmooth, of a red ferruginous colour[q].

It ſleeps with the leaflets converging above the petiole, and bent towards the baſe of it[r].

Native of Spain. Cultivated 1596, by Geraide. Flowering in july[s].

9. Root perennial, creeping widely. Stems from four to ſix feet in height when ſupported, otherwiſe trailing. Leaves unequally pinnate; leaflets oblong, ſmall, ſome in pairs, others alternate, deep green; the loweſt uſually approximate to the ſtem, like ſtipules, as in *C. coronata*, or are very ſmall. The flowers come out many together in roundiſh bunches, on peduncles which are about the ſame length with the leaves. The corolla varies from a deep to a light purple, to whitiſh and even wholly white; and ſometimes there is a mixture of both. The legumes are ſlender, and from two to three inches in length.

Linnæus obſerves, that the loweſt leaflets uſually approximate to the ſtem, like ſtipules, as in *C. coronata*, or are very ſmall. The peduncles are the length of the leaves.

Native

Native of France, Germany, &c. flowering from june to autumn. Cultivated in the time of Parkinſon, 1640[1]: as an ornamental plant.

This plant was formerly propoſed to be cultivated as a proper food for cattle; and it was found that it grew very readily, and might be very beneficial to the farmer. Mr. Miller informs us that he remembers to have ſeen a large ſpot of ground planted with it at Deepden near Dorking in Surry, at a ſeat of the Honourable Mr. Howard; where, although it had been neglected for ſome years, it was growing ſo rank as to get the better of all the weeds, brambles, &c. He found ſome of the branches upwards of five feet long, and very tender their whole length; ſo that a ſmall ſpot of ground will ſupply a conſiderable quantity of fodder, eſpecially in dry ſeaſons. Horſes and cows ſeemed to eat it greedily[2].

Mr. Curtis remarks, that its bitterneſs will be an objection to its being cultivated for cattle. A gentleman, however, who has lately ſown it on my recommendation, aſſures me that cows eat it very readily.

10. Stems aſcending, angular, even, two or three feet long. Leaflets fifteen, ſmooth, very obtuſe, with a point; the odd one not larger than the others. Stipules ſmall, patulous. Involucres very ſmall, many-leaved, mortified at top. Corollas blood-red; the ſtandard marked with purple veins; the wings convex on the outſide; the keel dark purple at the end. Legumes bent in[3], acuminate, near two inches long.

Native of Candia, whence Tournefort ſent the ſeeds to the Royal garden at Paris.

[Cultivated 1731, by Mr. Miller[4].]

11. This has a ſlender, hairy, twining ſtalk, of a brown colour, twiſting round any of the ſhrubs which ſtand near it, whereby it riſes eight or ten feet high; for the moſt part compoſed of five oval leaflets, one inch long, and half an inch broad, of a deep green. The flowers come out by pairs at each joint, ſtanding on very ſhort ſeparate peduncles erect; they are large, and of a pale yellow; theſe are ſucceeded by taper jointed pods, more than three inches long, which are covered with ſhort, ſoft, white, hairy down, and ſtand erect.

Diſcovered by Father Plumier in South America. Dr. Houſtoun ſent the ſeeds from Carthagena to Mr. Miller.

[12. Stem four feet high, upright, branched. Leaflets oblong, blunt, with a ſlender point. Flowers yellow, axillary. Calyx five-toothed, ſhort; the teeth nearly equal. Legume upright, filiform, toruloſe. Seeds ſubcylindric.

Native of Cochinchina[5].]

13. Mr. Miller deſcribes this ſort as being like the *glauca*, but the leaves having fewer leaflets; [in the ſpecific character, however, he ſays that the leaflets are eleven in this, whereas the *glauca* has only ſeven. From the largeneſs of the ſtipules I ſhould ſuppoſe it to be the ſame with the *Valentiana*.] According to Miller, the flowers are larger than thoſe of *glauca*, and have little ſcent.

14. Root perennial. Stem annual, erect, upwards of two feet high. Leaflets five or ſix pairs, oblong. Peduncles ſtrong, upwards of ſix inches in length, ſupporting large bunches of yellow flowers, ſucceeded by ſhort thick pods about an inch long. It flowers in june and july, and in warm ſeaſons the ſeeds will ripen in autumn.

Diſcovered by Tournefort in the Levant, whence he ſent the ſeeds to Paris. There is a variety with large white flowers.

PROPAGATION AND CULTURE.

1. This ſhrub is eaſily propagated by ſowing the ſeeds, which it commonly produces in great quantity, in march, upon a bed of light ſandy earth. Keep it clear from weeds, and in very dry weather refreſh it often with water, but gently, ſo as not to waſh the ſeeds out of the ground. When the plants are come up, watering in dry weather will promote their growth. At michaelmas, if the plants have thriven well, draw out the largeſt, and tranſplant them into a nurſery, in rows at three feet diſtance, and one foot aſunder in each row. The reſt of the young plants may remain another year before they are tranſplanted into the nurſery, where they ſhould continue two years, when they will be fit to plant out where they are to remain. If they are left in the nurſery longer, they are apt to make downright roots, the cutting off which is often fatal to the ſhrub; and in removing them at any time, care ſhould be taken not to break or wound the roots.

It may alſo be propagated by laying down the tender branches, which will take root in about a year's time, and may then be tranſplanted into a nurſery, and managed in the ſame manner as the ſeedling plants.

2, 4, 7. Theſe are propagated by ſowing the ſeeds in the ſpring, either upon a gentle hot-bed, or on a warm border of light freſh earth; and when the plants are come up about two inches high, they ſhould be tranſplanted either into pots, or a bed of good rich earth, at about four or five inches diſtance every way, where they may remain until they have obtained ſtrength enough to plant out for good; which ſhould be either into pots filled with good freſh earth, or a warm ſituated border; in which, if the winter is not too ſevere, they will abide very well, provided they are in a dry ſoil.

Some plants of the ſecond ſort ſhould be ſheltered under a common frame in winter, becauſe they are often deſtroyed in hard froſts; but in mild weather they ſhould be expoſed to the air, otherwiſe they will draw up weak.

3, 5, 6. Theſe are propagated by ſeeds; which may be ſown on a bed of light earth in april, and when the plants are fit to tranſplant, ſome of them ſhould be planted in a warm border, cloſe to a warm wall or pale, to which the branches ſhould be trained; obſerving to ſhade them from the ſun till they have taken freſh root, and alſo to refreſh them with water when they require it. After they are well rooted, they will require no other culture but to keep them clean from weeds, and faſten their branches to the wall; the next year they will flower, and if they are on a dry ſoil, and in a warm ſituation, they will continue many years. Some of theſe plants ſhould be pot into pots, that they may be removed into ſhelter in winter; where, if they are not too tenderly treated, they will flower great part of that ſeaſon; but theſe will rarely produce ſeeds, whereas thoſe in the full ground generally do, provided they are covered with mats in froſty weather.

8. Sow the ſeeds in borders of light freſh earth in the ſpring, where the plants are to abide, allowing them at leaſt two feet diſtance.

9. The roots creep very far under ground, by which it increaſes greatly, and when permitted to remain unremoved two or three years, it will overbear what plants grow near it; for which reaſon the roots ſhould be confined, and it ſhould be planted at a diſtance from any other plants. It will grow in almoſt any ſoil and ſituation, but thrives beſt in a warm ſunny expoſure, in which the flowers will be much fairer, and in greater quantities.

10. Sow the ſeeds on a bed of light earth in the ſpring, where the plants are deſigned to remain; thin them where too cloſe, and keep them clean from weeds. It is an annual, flowering in june, and ripening the ſeeds in autumn.—Native of the Archipelago, whence Tournefort ſent the ſeeds to Paris.

16. This plant is propagated by ſeeds, which ſhould be ſown early in the ſpring on a moderate hot-bed; and when the plants are come up, they ſhould be each tranſplanted into a halfpenny pot filled with freſh rich earth, and plunged into a hot-bed of tanners bark, obſerving to ſhade them until they have taken root; after which time they ſhould have air and water in proportion to the warmth of

[1] Hort. kew. [2] Mill. fig. [3] Linn.
[4] Hort. kew. [5] Loureiro.

the ſeaſon; and when they have filled theſe pots with their roots, they ſhould be ſhifted into pots of a larger ſize, and plunged into the hot-bed again, where they muſt remain until autumn, when they ſhould be removed into the ſtove, and plunged into the tan. Theſe plants muſt be conſtantly kept in the bark-ſtove, and placed among plants which require a moderate heat; where they will thrive and flower, and ſhould be ſupported by tall ſticks, round which they will twine as Hops do; for if they have not this ſupport, they will twiſt round other plants, and ſpoil them. Theſe are very proper plants to place againſt an eſpalier on the back part of the ſtove, amongſt other climbing plants, where they will make an agreeable variety.

If the plants are carefully managed in the winter, they may be preſerved two or three years, and will annually flower in july, and ſometimes they will produce ripe ſeeds in England.

14. This ſort is propagated by ſeeds, which ſhould be ſown on a warm border of light earth in the ſpring, and when the plants come up they muſt be carefully cleaned from weeds; when they are fit to remove, they ſhould be tranſplanted into a warm border, where they are to remain, ſhading them from the ſun till they have taken freſh root, after which they will require no farther care in ſummer, but to keep them clean from weeds; and in autumn, when the ſtalks are decayed, if the ſurface of the ground is covered with ſome old tan to keep out the froſt, it will be a ſecure method to preſerve the roots. The ſecond year the plants will flower, and, if the ſame care is taken in winter, the roots may be continued ſome years.

DESCRIPTION, *&c.*

Stems many, ſlender, round, with a few branches at the end, two or three inches long, covered with leaves. Theſe are alternate, of a kind of ſpatulate form, acuminate, ſmall, ſeſſile, of a glaucous hue. Stipules in pairs, acute, ſilvery. Flowers in glomerate racemes, ſeſſile, terminating. Calyx of a whitiſh bay colour, converging: corolla white[a].

[a] Krocker.

The fruit is a ſmall nut, covered with the permanent flower; it is cruſtaceous, wrinkled and tubercled, brown, one-celled and valveleſs. It incloſes a ſingle, ſubglobular, ſmooth, rufeſcent ſeed. A filiform umbilical chord aſcends from the baſe of the nut to the top of the ſeed. The embryo is roundiſh, inverted, pale yellow, and ſurrounds the albumen like a ring[a]. It flowers in june and july; and is annual.

Native of France, Germany, Denmark, Switzerland, Piedmont, in ſandy ſoils, uſually near the ſea or rivers.—Found by Mr. Hudſon on Slapham ſands beyond Dartmouth, and near the Star point.

Calyxes longer than the corolla.

DESCRIPTIONS, *&c.*

1. This plant ſends out many oblong ſmooth leaves, a little indented on the edges, and forming a ſort of head, like the Auricula. The peduncles come out in the centre of the leaves, riſe about four inches high, and ſupport an umbel of flowers, each on a ſlender, ſhort pedicel: they are of a fleſh colour, and ſpread open like thoſe of the Auricula.

[Leaves petioled, cordate, villoſe, toothed. Scapes eight or nine inches in height, erect, round, ſmooth at the top: pedicels many, one-flowered, umbelled, with ſtipules underneath. Corolla white or gold colour within, reddiſh violet or purple on the outſide. Diviſions of the calyx obtuſe, reflected[a]. Capſule ovate-oblong, marked with a flattiſh furrow on each ſide, two-valved, the valves when ripe frequently bifid at the end[b].

Native of the Alps, Auſtria, Sileſia, Siberia, flowering in april and may. According to Allioni it is biennial. Cultivated 1596, by Gerarde[c].]

2. Very like the firſt, but the flowers much ſmaller, and the calyxes larger. [Leaves reniform-cordate, lobed, with notches, the lobes rounded; they have

[a] Gærtner. [b] Krocker. [c] Gærtner.
[d] Hort. kew.

hairs

hairs ſcattered over them, and the petioles are long. The ſcapes are higher than the leaves. The umbel has about three flowers: the corolla is white, and the leaflets of the involucre are ovate[f]. Capſule ſmall, ovate-globular, in a bell-ſhaped calyx, gaping at top into five oblong revolute ſegments. Seeds about twenty, ſubovate, variouſly angled, rough-dotted, reddiſh brown.—This is a genuine ſpecies of Androſace, and has nothing in common with Cortuſa but the long petioles of the leaves[g].

Native of Siberia.]

PROPAGATION AND CULTURE.

Theſe plants are with great difficulty kept in a garden. The only method by which I could ever preſerve them, has been by planting them in pots, and placing them in a ſhady ſituation, where they were duly watered in dry weather; in this place they conſtantly remained both ſummer and winter, for the cold will not deſtroy them; the earth for theſe plants ſhould be light, and not too rich, for dung is very injurious to them. As they very rarely produce any ſeeds in England, the only method to propagate them is, by parting the roots in the ſame manner as is practiſed for Auriculas; the beſt time for this is about Michaelmas, ſoon after which the leaves decay.

Stipules linear, acute.

DESCRIPTIONS, *&c.*

1. [The common Hafel-nut or Nut-tree, is properly a ſhrub. The trunk is covered with a whitiſh cloven bark, which is ſmooth on the branches, frequently of a bay colour, and ſpotted with white; on the ſhoots it is ſometimes ſmooth, ſometimes hairy, aſh-coloured and green, with white tubercles. Leaves alternate, gaſh-ſerrate, wrinkled, with hairs on both ſides ſtanding out, dark green above, bright green beneath, on very hairy round petioles, half an inch in length: the midrib beneath is white and hairy; from that ſeveral white nerves proceed vertically; and between theſe is a veiny net[a].

The male catkins appear in autumn, and wait for the expanſion of the female gems in the ſpring. The ſtyles are of a bright red colour, long and ſetaceous[b]. The flowering branches, eſpecially thoſe which bear the fertile flowers, are ſet with ſhort fine hairs terminating in globules. The catkins are in pairs, of a yelloviſh green colour: the middle ſegment of the ſcales pointed at the end. Anther hairy[c].]

β. γ. White and Red Filberts. The ſhrubs of theſe varieties grow more erect than the common Hafel, and the ſtipules are different in ſhape. Mr Miller having found theſe not to vary, except in the ſize and colour of the fruit, makes them a diſtinct ſpecies.

[The involucre is tubular, fleſhy at bottom, turgid, thick, torn at top; the nut ovate-oblong and large. The outer ſkin of the kernel, in γ, dark red.

δ. The Cob-nut has a very large round fruit.]

ε. The Cluſter-nut has the fruit growing in great cluſters at the ends of the branches.

[The hafel, ſays Swinburn, has the name Avellana from Avellino, a city of the kingdom of Naples, about which it is cultivated. It covers the whole face of the neighbouring valley, and in good years brings in a profit of 60,000 ducats (£.11,250) The nuts are moſtly of the large round filbert, which we call Spaniſh. They were originally imported into Italy from Pontus, and known among the Romans by the appellation of *Nux Pontica*, which in proceſs of time was changed into that of *Nux Avellana*, from the place where they had been propagated with the greateſt ſucceſs.]

[f] Linn. ſyſt. [g] Gærtner.

[a] Pollich. [b] Lightfoot. [c] Withering.

The common hafel-nut is wild in many woods and coppices in England, whence the fruit is gathered in plenty, and ſent to the London markets by the country people.

[It alſo ſerves very well for thickening woods; and when allowed to grow, will make poles of twenty feet, but it is generally cut down ſooner for walking ſticks, fifhing rods, withes for faggotting, &c. for which purpoſes it is eſteemed a profitable wood.

The uſes of it recited by Evelyn are—for poles, ſpars, hoops, forks, angling-rods, faggots, cudgels, coals, and ſpringes to catch birds, withes and bands, the chips to purify wine, hurdles and wattling. He might have added, crates, ſpringles to faſten down thatch, the roots for inlaying or ſtaining. Where yeaſt is ſcarce, they twiſt the twigs, and ſteep them in ale during its fermentation, then hang them up to dry, and when they brew put them into the wort.

[2. This is remarkable for the length of the calyx, which continues to cover the nut entirely even after it is ripe.

Native of Virginia, in Dragon Swamps [d]. Introduced in 1745, by Archibald Duke of Argyle [e].

3. The leaves in this are a little laciniated at top. The raceme of nuts is very large [f].] The nuts themſelves are roundiſh, and in ſhape like thoſe of the common Hafel, but more than twice their ſize. The cups or involucres are alſo very large, ſo as almoſt to cover the nut, and are deeply cut at the brim.

Native of Conſtantinople. [Whence it was brought to Europe firſt in 1582, and again four years after, by David Ungnad Baron in Zorneck. Cluſius informs us, that when he left Frankfort in 1593, there was a ſhrub there above the height of a man, which had not then borne fruit, nor did it bear any two years after, though it continued to grow and flouriſh [g]. Linneus mentions a very large tree of it in the Leyden garden, in 1736, ſown there by Cluſius above a century before [h]. Cultivated here in 1665, by Mr. John Rea [i].]

PROPAGATION AND CULTURE.

All theſe ſorts may be propagated by ſowing their nuts in february; which, in order to preſerve them good, ſhould be kept in ſand in a moiſt cellar, where the vermin cannot come at them to deſtroy them, nor ſhould the external air be excluded from them, which would occaſion their growing mouldy.

The manner of ſowing the ſeeds being well known to every one, I need not here mention it, eſpecially ſince it is not the ſureſt way to obtain the ſorts deſired; for they ſeldom prove ſo good as the nuts which were ſown, or at leaſt not one in four of them will; and the method of propagating them by layers being not only the ſureſt, but alſo moſt expeditious, is what I would recommend to every one who would cultivate theſe trees for the ſake of their fruits.

[Having the ground well plowed and harrowed, let drills be drawn one yard aſunder, into theſe drop the nuts at about ten inches diſtance, and let them be covered with two inches of earth. They muſt be carefully weeded and thinned till the plants are left a yard aſunder each way. Or they may be raiſed in a nurſery, drawn from thence when they are from a foot to two feet high, and planted finally at the diſtance before mentioned. In twelve years they may be cut down for poles, but may afterwards be cut every ſeventh or eighth year.

The Filbert can only be kept true to its kind by ſuckers or layers; which laſt make the beſt trees. In ſome parts of Kent plantations of Filberts are much attended to. The trees are never ſuffered to riſe above ſix feet in height, and are regularly pruned like Gooſeberry buſhes. They are planted at the diſtance of twelve feet, and when full ſpread, the cup formed by the branches is ſix feet diameter. The ſpaces are cultivated with hoeing crops, the vigour of the trees depending on the ſtirring of the ground [k].

It is the uſual mode in Kent to raiſe them in hop-grounds, where ſometimes cherry, but more commonly apple-trees are alſo planted. They know nothing of raiſing them from layers, but do it from ſuckers, which it is the beſt way to train previouſly in a nurſery. The beſt ſoil is a ſtrong loam, with a clayey or marley bottom, in Kent termed coomy, whereon they bear greatly; the fruit is large and fine, and not maggotty. An acre has ſometimes been ſold for £. 50 [l].

GENERIC CHARACTER.

CAL. *Spathe* univerſal compound, *Spadix* branching.

COR. three-parted. *Petals* ovate, obtuſe, ſpreading.

STAM. *Filaments* ſix, ſubulate, longer than the corolla. *Anthers* adnate.

PIST. *Germ* roundiſh. *Style* ſubulate, ſhort. *Stigma* ſimple.

PER. *Berry* globoſe, large, one-celled.

SEED ſingle, bony, large, globoſe.

OBS. Browne *deſcribes his Corypha in a different manner*: is it therefore of a different genus?

CAL. *Spadix* ſimply branched, imbricated with proper ſpathes. *Perianth* none.

COR. none.

STAM. *Filaments* ſix, ſhort, growing into the ſides of the germ. *Anthers* oblong.

[a] Dav. van Royen, in Linn. ſyſt.
[b] Dav. van. Royen, in Linn. ſyſt.
[c] Linn. ſuppl.
[d] Linn. ſuppl.

PIST. *Germ* globoſe, ſmall; *Style* ſimple, ſhort. *Stigma* headed, ſomewhat funnel-form.

PER. *Drupe* one-celled.

SEED. *Nut*, with a bony aril.

ESSENTIAL CHARACTER.

Flowers hermaphrodite, ſix-ſtamened. *Spathe* many-leaved (none. *Cal.* ſix-leaved. *G.*) *Cor.* three-petalled (none. *G.*) *Piſt.* one. *Berry* globoſe, ſuperior, one-ſeeded. *Seed* bony, globoſe.

SPECIES.

1. Corypha umbraculifera. *Great Fan-Palm.*
Lin. ſpec. 1657. *ſyſt.* 984. *Reich.* 4. 633. *hort. cliff.* 482. *Gærtn. fruct.* 18.
Palma montana, fol. plicatili ſabelliformi maximo ſemel tantum frugifera. *Raii hiſt.* 1367.
Codda-panna. *Rheed. mal.* 3. *p.* 1. *t.* 1—12.
Saribus. *Rumph. amb.* 1. 42. *t.* 8.
Fronds pinnate-palmate plaited, and having a thread between them; ſtipes ciliate-ſpiny.

2. Corypha minor.
Lin. ſyſt. 984. *Jacqu. hort. vind.* 3. *p.* 8. *t.* 8.
Fronds palmate fan-ſhaped plaited ſubbifid, having a few threads interpoſed; ſtipes unarmed.

DESCRIPTIONS, *&c.*

1. The cruſty covering of the ſeed cannot be accounted a ſhell, and therefore the pericarp is not a drupe; becauſe this cruſt forms the very papilla with which the embryo is covered[b].

This tree ſcarcely flowers before it is thirty or forty years old[c].

One ſpecies of this tree, which is the *Codda-panna* of the hortus malabaricus is very large; it has palmate-pinnatifid leaves, with a petiole (or ſtipe) of tender thorns; a ſecond, which is the *Saribus* of Rumphius, has the leaves plaited in a radiate form palmate-peltate, with the petiole as in the other; a third ſmaller, which is the *Sabal* of Adanſon, with palmate leaves, an unarmed petiole, and a fruit in the ſhape of a pea. Perhaps theſe may be different ſorts[d].

Rumphius is of opinion that his *Saribus* is a diſtinct ſpecies from the *Codda-panna* of the Hortus Malabaricus, and Loureiro deſcribes it as ſuch. The latter has alſo two other ſpecies; one which he calls *Corypha africana*, an inhabitant of the eaſtern coaſt of Africa; and the other, *Corypha pilearia*, which is figured in Rumphius, vol. 1. *t.* 9. and is *Rhapis Liguala.*

Native of Malabar and the iſland of Ceylon. The Marqueſas and Friendly iſlands.

Cultivated before 1742, by Robert James Lord Petre[e].

Knox deſcribes the great Fan Palm under the name of *Tallipot*. It is as big and tall as a ſhip's maſt, and very ſtraight. The leaves are of great uſe, one being ſo broad and large that it will cover fifteen or twenty men. Being dried, it is very ſtrong and limber; and though it be very broad when open, yet it will fold cloſe like a fan, and then is no bigger than a man's arm. The whole leaf ſpread is round, but is cut into triangular pieces for uſe: theſe they lay upon their heads as they travel, with the narrow end foremoſt, to make their way through thickets. Soldiers all carry them, not only to ſhade them from the ſun, and to keep them dry in caſe of rain on their march, but to make their tents for them to lie under. Theſe leaves all grow on the top of the tree. It bears no fruit until the laſt year of its life, and then yellow bloſſoms moſt lovely to behold, but ſmelling very ſtrongly, come out on the top, and ſpread abroad in great branches: theſe come to a fruit round and very hard, as big as our largeſt cherries; in ſuch abundance that one tree will yield ſeed enough for a country; but not good to eat. The flowers ſmell ſo ſtrong, that they cut down the trees where they are near houſes. The trunk within is a pith only, which they beat in a mortar to flour, and bake cakes of it, which taſte much like white bread[f].

[b] Gærtner.
[c] Linn. ex hort. malab.
[d] Juſſieu.
[e] Hort. kew.
[f] Hiſt. of Ceylon, p. 15.

The leaves alſo ſerve for covering their houſes, and for writing on with an iron ſtyle. Moſt of the books which are ſhown in Europe for the Egyptian papyrus, are made from the leaves of this Palm.

2. Leaves ſubradical, ſmooth, rigid, ſtriated; petiole without prickles, channelled or flat above, round underneath; the ſegments of the leaf are enſiform and acute. Spadix erect, round, ſmooth, from three to five feet high, axillary, clothed with membranaceous ſheathing ſpathes, whence iſſue along the whole of the ſpadix panicled racemes, angular, ſmooth and firm. Flowers ſeſſile, ſmall, without ſcent, all hermaphrodite, numerous. Perianth three-leaved, ſmall, permanent, whitiſh; leaflets roundiſh, concave, very blunt. Petals three, oblong, blunt, concave, deciduous, white, ſpreading. Filaments thick, white, the length of the corolla; three alternate with the petals, the other three lying on the petals ſo that the anthers only emerge from their tops: theſe are ſagittate and incumbent. Germ ſuperior, three-cornered-roundiſh, pale; ſtyle conical, three-furrowed, erect, white, a little ſhorter than the ſtamens; ſtigma blunt. Fruit the ſize of a pea, and of a ſweet taſte, ſmooth, black, not very ſucculent. Shell membranaceous, thin, brittle, browniſh, containing a flatted-roundiſh, bony, ſhining kernel.

It flowered firſt in Europe in the imperial garden at Schoenbrunn, in 1773 [b].]

COSTMARY. See *Tanacetum*.

COSTUS. (*Κόστος*, Gr. *a name borrowed from the Arabic.*)

Lin. gen. n. 3. *Reich.* 3. *Schreb.* 4. *Muſ. Cliff.* 14. § 2. 3. *Juſſ.* 63.

Claſſ. 1. 1. Monandria Monogynia.

Nat. order of *Scitamineæ.—Cannæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* three-toothed, very ſmall, ſuperior.

COR. *Petals* three, lanceolate, ſomewhat erect, concave, equal. *Nectary* one-leafed, large, oblong, tubular-inflated; two-lipped: *Lower lip* broader, longer than the corolla: *Border* ſpreading, three-cleft; middle diviſion three-parted. *Upper lip* lanceolate, ſhorter, doing the office of a filament.

STAM. The office of a *Filament* is performed by the upper lip of the nectary, to which grows a two-parted *Anther*.

PIST. *Germ* inferior, roundiſh; *Style* filiform, length of the filament. *Stigma* headed, compreſſed, emarginate.

PER. *Capſule* roundiſh, crowned, three-celled, three-valved.

SEEDS many, three-cornered.

OBS. *Linneus now calls the* Nectary *an interior ringent Corolla, whoſe upper lip is three-parted, and the middle emarginate.* R.

Juſſieu calls the corolla an interior calyx.

ESSENTIAL CHARACTER.

Cor. inner, inflated, ringent: the lower lip trifid.

SPECIES.

1. Coſtus arabicus. *Arabian Coſtus.*

Swartz prodr. 12. *Linn. hort. cliff.* 2. *Mer. ſurin. t.* 36.

Leaves ſmooth on both ſides, ſpike few-flowered, ſcales leafy at the tip, the upper ones faſtigiate.

3. Coſtus ſpicatus.

Swartz prodr. 12.

Alpinia ſpicata. *Lin. ſyſt.* 51. 2. *Jacqu. amer.* 1. *t.* 1.

Leaves ſmooth on both ſides, ſpike many-flowered, ſub-ovate, cloſely imbricate, ſcales ovate, ſimple.

4. Coſtus malaccenſis.

Retz. obſ. 3. 71. *n.* 18.

Leaves very finely tomentoſe underneath, raceme terminating, bunches ſix-flowered.

[c] Jacquin.

DESCRIPTIONS, *&c.*

1. Root perennial, irregular, two inches thick, knotty. Stems annual, ſimple, round, three or four feet high, near an inch in diameter at bottom, fleſhy, with a ſtrong bark, ſheathed all over. Leaves alternate, lanceolate, acuminate, quite entire, coriaceous, the largeſt a foot long, on a ſhort, thick, ſheathing petiole; green and ſmooth above, paler and very ſoft underneath. Spike very handſome, terminating, ſubſeſſile, ſolitary, erect, cloſe, as big as the hand cloſed. A pair of ſpathes to each ſeſſile flower; the outer ovate, acute, concave, coriaceous, broad, blood-red, the other oblong, only one third of the breadth, concave, purple at the tip, placed on the right ſide of the flower, which it embraces. Calyx in the flower green, with a purple tip, in the fruit entirely blood-red. Petal and nectary fleſh-coloured; ſometimes almoſt white. Anthers white. Seeds black, without ſmell, but having an unpleaſant taſte: there is a white fungoſe ſubſtance adhering to the baſe by which they are connected together [b].

Native of the Eaſt Indies. Cultivated 1752, by Mr. Miller [d].]

The roots were formerly imported from India, and were much uſed in medicine; but of late years they have not been regarded, the roots of Ginger being generally ſubſtituted for them.

[2. Spike or head of flowers imbricate, with ovate, blunt, concave ſcales, each one-flowered, permanent, green, not coloured [e].

Native of the Weſt Indies.

3. Root perennial, fleſhy, irregular, white. Stems ſomewhat jointed, almoſt upright, round, ſmooth, one or two feet in height. Leaves oblong, acuminate, attenuated at the baſe, ſhining, quite entire, alternate, on a very ſhort round petiole; the floral leaves below the ſpike commonly in fours. Spike conical, ſolitary. Spathes very cloſely imbricate, ſcarlet, thick, coriaceous, one-flowered. Flowers yellow without ſcent, quickly withering [f].

Native of the Caribbee iſlands, by the ſide of torrents.

In Martinico it is called *Canne de riviere*, and a decóction of the roots and ſtalks is often given in the Gonorrhœa, &c. as a cooling drink [g].

4. Stems ſeveral, approximating, upright, ſimple, a little compreſſed, ſmooth, clothed with the ſheaths of the leaves, half as high again as a man, ſomewhat incurved towards the top. Leaves alternate, ſubbifarious, the lower ones ſpreading, the upper ones almoſt upright, oblong, acuminate, roughened with briſtle-ſhaped toothlets on the edge; above ſmooth, even, with remotiſh nerves at an acute angle, bright green, a foot and half long, and more than a hand broad. Petioles faſtened to the ſheaths, ſemicylindric, channelled, ſmooth, ſhort. Sheaths opening on the ſide, ſmooth, ſtriated, longer than the ſpace between them, the mouth ovate-oblong, membranaceous, ciliate, acute. Raceme terminating, emerging from the ſheaths of the upper leaves, on one ſide, looſe, nodding. Common peduncle incurved, jointed towards the middle, ſheathed, round, ſomewhat hairy, red, more than a hand long, ſcarcely the thickneſs of the little finger. Partial peduncles involucred at the baſe, and ſomewhat compreſſed, becoming afterwards almoſt round, club-ſhaped at top, hairy, curved, much longer than the bunches of flowers. Theſe are crowded, ſeſſile, commonly ſix-flowered and involucred. Each flower has alſo its proper involucre. The involucre near the middle is faſtened to the common peduncle, and ſurrounds it at the baſe; it is inflated, oblong, acuminate, ending in a long twiſted apex, ſtriated, hairy, membranaceous, larger than the reſt, pale red. The ſecond, third and fourth are longer than the partial peduncles, but the reſt are ſmall; they are all inflated, membranaceous, and of one colour. The involucres of the bundles of flowers are perforated

[b] Jacqu. collect. [d] Hort. kew. [e] Linn. cliff. [f] Jacqu. amer. [g] Ibid.

or bell-ſhaped, ſubtriquetrous, obſcurely toothed at the edge, membranaceous, ſmooth, ſhorter than the calyxes. All the flowers, eſpecially the laſt, are on very ſhort, club-ſhaped pedicels, ſomewhat compreſſed.

Native of thick woods near Tſing, in the neighbourhood of Malacca.

Characters of the fructification are given by Swartz, in his obſervations, from the three firſt ſpecies. Of the firſt by Jacquin in his Collectanea: of the ſecond by Linneus in his Hortus Cliffortianus: of the third by Jacquin in his Hiſtoria Stirpium Americanarum: and of the fourth by Retzius in his Obſervationes.]

PROPAGATION AND CULTURE.

Theſe are propagated by parting the roots; the beſt time for doing this is in the ſpring, before the roots put out new ſtalks. The roots muſt not be divided too ſmall, becauſe that will prevent their flowering. They ſhould be planted in pots, filled with light kitchen-garden earth, and plunged into the tan-bed in the ſtove, where they ſhould conſtantly remain, and may be treated in the ſame manner as the Ginger, which is fully treated of under the article AMOMUM.

Leaves alternate, almoſt ſtem-claſping, oblong, toothed, flowers ſolitary, ſeſſile, oppoſite to the leaf.

15. Cotula bicolor.
Forſt. fl. auſtr. n. 540.

DESCRIPTIONS, &c.

1. Root annual. Stem about ſix inches high, at firſt erect, then procumbent, ſcarcely flexuoſe, tender, pubeſcent: branches alternate, more conſpicuouſly pubeſcent, incurved, turned up, ſpreading. Leaves pinnatifid-ſinuate; ſegments diſtant, ſparingly ſerrate or entire, blunt; they are ſmooth, ſpread-

ſpreading, alternate, ſeſſile. Peduncles one-flowered, filiform, erect, villoſe. Flowers drooping, much compreſſed before they open, the ſize of a lentil. Florets yellow. Leaflets of the calyx ovate-oblong, obtuſe, concave, with a white membranaceous edge. Corollets in the ray none, but naked piſtils concealed beneath the calycine leaflets, with a bifid ſtigma. Seeds of the ray roundiſh compreſſed, flat on the inſide, a little keeled on the outſide: of the diſk rather oblong, almoſt triquetrous. Down none. Receptacle naked [a].

Native of Spain and the iſland of St. Helena. Cultivated 1732 by James Sherard, M.D. [b]

β. So nearly allied to *C. anthemoides*, that it is doubtful which genus it belongs to. Flowers nearly globular; leaflets of the calyx equal, with a membranaceous edge. Native of Egypt [c].

2. The flowers have no chaffs; the florets are four-cleft. Native of Spain and other ſouthern parts of Europe. Annual [d].

3. Stem herbaceous, five feet high, erect, ſomewhat angular, even, (as is the whole plant,) covered with a blueiſh dew. Leaves alternate, ſeſſile, lanceolate, with ſcattered hairs and crowded hollow dots, eſpecially underneath. Peduncles terminating, almoſt leafleſs, one-flowered. Calyx many-leaved, equal; leaflets lanceolate, acuminate, ciliate. Corollets of the diſk four-cleft [e]. This and ſome of the other ſpecies (viſcoſa, turbinata, capenſis) having radiate flowers, are ſeparated under the name of *Lanciſia* by Pontedera and Adanſon [f]. Juſſieu reduces this to the *Lidbeckia* of Bergius; and the *turbinata* to the *Cenia* of Commerſon. Native of the Cape of Good Hope.—It flowers in may and june. Introduced 1774, by Mr. Francis Maſſon [g].

4. This ſort is an annual plant, which ſends out trailing ſtalks about ſix inches long, with ſucculent leaves, in ſhape like thoſe of Buckſhorn Plantain. The flowers grow from the diviſions of the ſtalks upon ſhort weak foot-ſtalks, being deſtitute of rays; they are of a ſulphur colour, and appear in july. The flowers of this and the eighth ſort ſtand erect, when they firſt appear, but ſo ſoon as the florets are impregnated, and their colour changes, the foot-ſtalks become very flaccid toward the top, and the flowers hang downward; but when the ſeeds are ripe, the foot-ſtalks become ſtiff, and the heads ſtand erect for the winds to diſperſe the ſeeds.

[Receptacle conical, depreſſed, tubercled, naked, rayed with the pedicels of the female florets. Seeds of the ray larger, obovate, emarginate at the tip, on a filiform pedicel, flattiſh or grooved on one ſide, keeled with an obtuſe angle on the other, ſmooth, compreſſedly triquetrous, whitiſh, bald. Seeds of the diſk ſmaller, oblong-elliptic, flattiſh, with a whitiſh rim, but rufeſcent in the middle, ſeſſile, ſmooth, bald. No rim at the vertex of the ſeed [h].

This is a Cape plant; but has now eſtabliſhed itſelf in Europe. Cultivated in 1714 [i].

5. Stems round, hirſute, a foot and half in height. Leaves alternate, much crowded, narrow-lanceolate, reſembling thoſe of *Protea argentea*, hirſute on both ſides, almoſt a finger's length. Umbel terminating, five-flowered. Peduncles one-flowered, hirſute, with ſome alternate almoſt leafy ſcales. Calyx ſubimbricate, villoſe; the inmoſt ſcales higher than the diſk, ſubulate, even on the inſide, and coloured. Corolla without any ray; diſk hemiſpheric. Seeds flatted, obovate, crowned; the edge obſcure, ſcarcely three-lobed. Receptacle naked.—Native of the Cape [k].

6. Stems ſimple, ſubpubeſcent. Leaves petioled, alternate, hoary underneath; lobes half-ovate, equal, mucronate. Peduncles one or two, long: (bracte lanceolate, ſmall) one-flowered, erect. Calyx with equal, pubeſcent ſcales.—It agrees very much in the flower with *C. ſtricta*; and they might make a ſeparate genus.—Native of the Cape [l].

[a] Murr, prodr. [b] Dill. elth. [c] Linn. ſpec. [d] Linn. [e] Linn. mant. [f] Gærtner. [g] Hort. kew. Philoſ. tranſ. [h] Gærtner. [i] Hort. kew. from Linn. ſuppl. [k] Ibid.

7. This is a procumbent plant, or at leaſt declining, putting forth many ſuckers from the root. Stem a *ſpan* high. Leaves very like thoſe of common *Groundſel* (*Senecio vulgaris*), ſinuated, villoſe, viſcid. Flowers like thoſe of the firſt ſpecies, but on ſhorter peduncles, and with the calyx more rounded: the florets alſo much reſemble thoſe of C. anthemoides, but the females have a very ſlender linear corolla. Seeds naked, inſerted into the corolla on the inner ſide, near the tip. Receptacle conical, naked.

Found by Houſtoun at La Vera Cruz, and ſent to Linneus by Miller [m].]

8. This ſends out many branching ſtalks, which ſpread on the ground. Leaves very finely divided, covered with a cottony ſubſtance. Flowers ſolitary, on long peduncles, from the ſide of the branches; they have a narrow border of white rays, with a pale yellow diſk. [Receptacle fiſtulous, with minute equal calycine leaflets at the edge of it. Ray of the corolla very ſhort, ovate, white, red underneath [n]. Seeds diſform, thoſe in the ray on pedicels [o]. Annual. Native of the Cape of Good Hope.

Cultivated 1713, in the botanic garden at Chelſea. It flowers in july and auguſt [p].

9. Stem ſcarcely ſuffruticoſe, but rather entirely herbaceous, more than a foot high, upright, ſlightly angular, firm, pubeſcent, pale green, very much branched on every ſide. Branches ſcattered, almoſt ſimple, nearly erect, clothed all over with leaves and rudiments of branches, axillary, ſlender, corymbiferous. Stem-leaves ſcattered, at the origin of the branches, pinnate-multifid; pinnas almoſt oppoſite, doubly pinnatifid, glaucous, ſubvilloſe, petioled. Branch-leaves alſo petioled, pinnate; pinnas almoſt oppoſite, linear, toothed, blunt; teeth ovate-acute. Petioles linear, channelled above, convex beneath, claſping, appendiculed at the baſe with ſtipules or gaſhed leaflets. Corymb of flowers compound, faſtigiate, large, terminating, conſiſting of ſeveral corymbiferous branches. Peduncles long, grooved, pubeſcent, ſubumbelled, one-flowered, with linear, alternate ſcales [q]. Scarcely any female florets; thoſe of the diſk four-cleft. Annual [r]. Native of the Cape of Good Hope.

10. This has the appearance of Chamomile. Stems many, very much branched, diffuſed, a ſpan in height, round, ſomewhat gloſſy. Leaves naked, without dots; the rib ſcarcely flatted; with cylindric teeth purpliſh or browniſh at the end. Peduncles terminating, longiſh, one-flowered, ſtriated. Calyx imbricate, a little ſcarioſe. Corollets of the ray diſtant, ſubpedicelled, marked with lines, neutral, white—of the diſk four-cleft. Diſk convex, yellow. Receptacle half-ovate. Annual. Native of the Cape [s].

11. Stem erect, ſubfaſtigiate, with a panicle. Leaves *bipinnate, like thoſe of Tanſey*. Heads without any ray; florets four-cleft. Native of the Cape [t].

12. Root perennial. Stems herbaceous, ſhort, tomentoſe, ſimple, procumbent, white. Leaves petioled, white, ſilky, like thoſe of Wormwood. Scapes terminating, ſolitary, very long, naked. Flowers ſolitary, like thoſe of the fourth ſpecies. Calyx hemiſpheric, with the ſcales nearly equal, obtuſe and ſcarioſe at the end. Corolla floſculus, ſhorter than the calyx, yellow. Native of the Cape [u].

13. Stem herbaceous, dichotomous. Leaves ſomewhat obtuſe, ſlender. Peduncles terminating from the forks of the ſtem, longer than the leaves. Flower exactly ovate, white, with four-cleft corollets. Chaffs the length of the florets [x].

14. Native of New Caledonia. Found ſeptember 13th, 1774.

15. Native of the iſle of Tanna in the South Seas.]

[l] Linn. cliff. [m] Linn. mant. Pontedera. Bergius. [n] Linn. ſuppl. [o] Gærtner from Linn. mant. [p] Hort. kew. [q] Linn. mant. [r] Linn. ſyſt. [s] Ibid. [t] Linn. mant.

PROPAGATION AND CULTURE.

1, 2. If the ſeeds be permitted to ſcatter, the plants will come up in the ſpring, and require no other care but to keep them clean from weeds, and thin the plants where they are too cloſe.

3. This, and the other Cape ſorts muſt be raiſed on a moderate hot-bed in the ſpring, and when the plants have obtained ſtrength, they may be tranſplanted into a warm border, where they will ripen their ſeeds very well. [They all flouriſh beſt, however, under the protection of the dry ſtove; and ſeveral of them may be increaſed not only from ſeeds, but freely from cuttings.

C. orbiculata. *Forſk. arab.* 112.
Leaves orbiculate-ſpatulate, quite entire, flowers panicled, ſmooth, quadrifid.

DESCRIPTIONS, &c.

1. This and moſt of the other ſpecies are natives of the Cape of Good Hope.—The firſt ſort varies much in the form of the leaves, &c. Some of theſe varieties are made diſtinct ſpecies, and are thus deſcribed by Mr. Miller.]

γ. This has a ſhort thick ſucculent ſtalk, which rarely riſes more than a foot high, branching out on every ſide, ſo as to ſpread over the pots in which it is planted. The branches become woody by age, and are cloſely beſet by thick round leaves of a grayiſh colour, with purple borders, plane on their upper ſide, but convex on their under, and very fleſhy, of an herbaceous colour within, and full of moiſture.

δ. This alſo has a thick ſucculent ſtalk, which by age becomes woody, and riſes three or four feet high, ſending out crooked branches, which grow irregular, with thick fleſhy ſucculent leaves about two inches long, and near as wide towards the top; they are narrow at the baſe, and rounded at the top, of a ſea green colour, with a purple edge, which is frequently irregularly indented. Flowers on thick ſucculent peduncles, from the ends of the branches, near a foot long, naked, and ſupporting eight or ten flowers, hanging down, tube long, brims turning back. Stamens and ſtyles longer than the tube, and hanging down.

[Introduced 1690, by Mr. Bentick. They flower from july to ſeptember [a].]

2. This has a ſhort greeniſh ſucculent ſtalk, ſeldom more than a ſpan high, dividing into ſeveral irregular branches. Leaves thick, ſucculent, four inches long, half an inch broad, and as much in thickneſs, having a broad concave furrow on their upper ſide, and convex on the under, bright green, with a purple tip. Peduncles terminating, near a foot high. Flowers on ſhort pedicels, yellow; tubes long, brims reflex, tipped with purple. Stamens longer than the tube.

[Stem very thick, with obtuſe branches, leafy at the end only. Leaves naturally oppoſite, (in monſtrous plants alternate) ſpatulate-lanceolate, fleſhy, obtuſe, petioled. Scape terminating, a foot high, ſubumbelled and divaricated [b].

Cultivated 1731, by Mr. Miller [c].

3. This is a perennial plant, a long ſpan in height. Stem, for one third part at bottom, where it is covered with leaves, perpendicular; the other two thirds, which are clothed with flowers, bent in form of an S, thick, angular, ſtiff. Leaves very much crowded, imbricate all round, ſucculent, compreſſed, flattiſh above, angular on the back, ending in a prominent bump, having a flexile white ſpine at the tip; the loweſt thinner, longer, broader and abrupt, with a cartilaginous border at the end, and ſpreading; the upper ones narrower, and more erect. Spike terminating, compound at the baſe: the loweſt ſpikelets elongated, many-flowered, ſpreading, peduncled, but the flowers ſeſſile; the ſpikelets above theſe are very ſhort, and have few flowers or four heaped together; above theſe the flowers are ſolitary and ſeſſile to the top of the ſtalk. Under each ſpikelet and flower is a ſucculent, ſubulate, incurved bracte, ending in a ſpine. Perianth five-parted, the parts connected at the baſe, nearly equal, lanceolate, concave, acute, converging. Corolla four times as long as the perianth, conſiſting of five white, linear, converging concave petals, connected at the baſe. Nectary ſurrounding the germ, compoſed of five roundiſh, concave, emarginate, yellow ſcales. Filaments almoſt equal, longer than the corolla: anthers cordate. Piſtils a little ſhorter than the ſtamens: germs ſuperior, ending in divaricate ſtyles [d].]

Native of Siberia, whence it was brought to the imperial garden at Peterſburgh. Mr. Miller received it from Dr. Amann. It flowers in april, and ſometimes bears ſeed in England.

4. This has a thick ſucculent ſtalk, rarely more than a ſpan high, dividing into many branches. Leaves ſhort, thick, ſucculent, not more than half an inch long, and a quarter of an inch broad, grayiſh with green ſpots, ſeſſile. Peduncles terminating, ſix inches long, naked, ſupporting five or ſix flowers; alternate, ſeſſile, greeniſh, with purple tips.

[Cultivated 1732, by James Sherard, M. D. [e].]

5. Stalk upright, ſucculent. Leaves oblong, thick, ſucculent, alternate. Flowers purpliſh, in a looſe ſpike, two or three joined on the ſame peduncle, which is very ſhort. It is a biennial plant, and the ſeeds ripen in autumn.

Native of Candia and Siberia.

[Cultivated 1732, by Dr. Sherard [f].

6. Mr. Hudſon has diſtinguiſhed the yellow from the common Navel-wort, by the circumſtances of the flowers being upright, and the bractes toothed in the firſt, whereas in the ſecond, the flowers hang down, and the bractes are entire. Moriſon remarks alſo, that the root of the yellow Navel-wort is not round like a turnep, but oblong and creeping; the leaves larger and growing more cloſe, not ſo perfectly peltate, but more open about the inſertion of the petiole.—Mr. Woodward obſerves that the flowers are not always pendant in the ſmaller ſpecimens of common Navel-wort.

α. Yellow Navel-wort is found in Somerſetſhire, and in the weſt riding of Yorkſhire [g].

β. Root tuberous, roundiſh. The whole plant is ſucculent, and has a ſhining, froſted appearance. Stem nearly upright, ſlightly angular, from ſix to nine inches high, frequently purple. Leaves thick, fleſhy, circular, concave on the upper ſurface, with a hollow dimple nearly in the centre, juſt oppoſite to the inſertion of the petiole, which is round.] From this appearance this plant has the name of Navel-wort. The lower leaves in ſome plants are kidney-ſhaped. The ſtem-leaves reſemble the root-leaves, but are not ſo exactly circular, and the petiole not fixed ſo near the centre. Flowers in long terminating bunches, of a white greeniſh hue. The ſpike is ſometimes ſimple, ſometimes branched towards the bottom. At the baſe of each peduncle is a lanceolate bracte. Segments of the calyx lanceolate-ovate, extending more than half way down. Corolla tubular, five-cornered, the ſides flat; ſhrivelling, permanent: the ſegments acute, ſtriated. Nectary and anthers yellow. Filaments alternately longer and ſhorter [h].

Native of Judæa, Spain, Portugal, Italy, Britain: on moiſt rocks and walls. With us in an old gravel pit at Highberry-barn, near London. At Peterborough, Northampton—and Thorpe, between Peterborough and Wandesford. Slate-pit rocks at Smithland in Leiceſterſhire.—Church Brampton in Northamptonſhire. About Troutbeck in Weſtmoreland. In Cornwall and other parts of the weſt. Godſlow bridge in Oxfordſhire. About Malvern in Worceſterſhire. Skipton-Mallet in Somerſetſhire. Caernarvonſhire and Merionethſhire in Wales. In ſome of the Scotch iſlands—as Arran, Y-columbkil, &c.—It flowers from june to auguſt.

7. Root fibroſe. Stem ſimple, columnar, almoſt erect, a finger's length in height. Leaves blunttiſh, ſeſſile, ſomewhat hairy, ſtarriſh above, dotted with duſky red. Flowers in a terminating corymb. Corollas funnel-ſhaped, duſky red on the outſide, ſomewhat hairy: border plane, acute, red above, with three purple ſtreaks, and a purple tip. Filaments thickiſh and a little prominent: anthers very ſmall. Calyx ſhort.—The appearance of the herb is that of Sedum album.—Native of Africa, the Levant, and Spain.—Biennial [i].

8—13. Found at the Cape of Good Hope by Thunberg.—The 11th has its trivial name, from its yellow flowers reſembling thoſe of Cacalia. As the 12th alſo has from its reſemblance to Statice reticulata [k].

14. Stem leafy to the very top. Leaves dilated at the baſe, the ſegments three or five, unequally ferrate, except the floral ones, which are linear and entire. The inflorescence paniced. Calyx very

[a] Hort. kew. [b] Linn. mant. [c] Miller. [d] Hort. kew. [e] Dill. elth. [f] Ibid. [g] Hudſon. [h] Linn. With. Stoker, Hudſ. Woodw. Mſs. [i] Linn. ſuppl. [k] Linn. ſpec.

ſmooth and glaucous, as is alſo the corolla; the border of which is yellow on both ſides, uſually four-cleft, but in ſome few flowers five-cleft. Stamens eight ſhort, two long[1].]

According to Miller, the ſtem is upright, about a foot high, jointed and ſucculent. Leaves broad, deeply cut on their edges, of a grayiſh colour, oppoſite, almoſt embracing. Peduncles terminating, about ſix inches long, ſuſtaining ſeven or eight ſmall flowers of a deep yellow colour. Stamens not longer than the ſhort tube.

[Native of Egypt and the Eaſt Indies. It flowers in july and auguſt, and was cultivated by Mr. Miller in 1731[2].

15. Stem at the end almoſt naked. Leaves obſcurely ſerrate, linear at the baſe. Inflorescence cymed; the pedunckes dichotomous. Calyx and corolla pubeſcent on the outſide; the border of the latter ſcarlet on the upper ſurface, paler on the lower. Stamens eight, as in the foregoing, from which it is diſtinct[3].

16. This has been confounded with the ſecond ſort, and ſhould be placed next to it. It flowers from july to ſeptember; and was cultivated in 1759, by Mr. Miller[4].]

17. This has the appearance of a Sedum. Root annual. Stem filiform, brachiate, a palm in height. Leaves fleſhy, obtuſe. Pedunckes at the ends of the branches, commonly ſimple, ſeldom branched. Flowers racemed, diſtant. Pedicels capillary, looſe. Leaflets of the calyx lanceolate, villoſe-viſcid. Corolla bell-ſhaped, pale yellow, with purple ſtreaks. Native of the mountains of Spain near Toledo, and elſewhere.

18. This reſembles Cotyledon laciniata in habit, inflorescence, and ovate yellow corollas; but differs in having lanceolate leaves; and the ſtem, pedunckes, calyx and corolla villoſe.

19. The whole of this plant is ſmooth. Partial pedunckes alternate. Corolla ovate, like that of C. laciniata, membranaceous, narrowed at top; the ſegments lanceolate, reddiſh-yellow[5].]

PROPAGATION AND CULTURE.

1, 2, 4, 8—13, 16. The African kinds are all propagated by planting cuttings in any of the ſummer months, which ſhould be laid in a dry place for a fortnight or three weeks after they are taken from the plant, before they are planted: for theſe abound with juice through every part of the plant, which will certainly rot the cuttings, if they are not ſuffered to lie out of the ground, that the wounded part may heal over, and the great redundancy of ſap evaporate. The ſoil in which theſe plants thrive beſt, is one third freſh light earth from a paſture, one third ſand, and the other third part lime-rubbiſh and rotten tan, in equal quantities; theſe ſhould be well mixed, and laid in a heap ſix or eight months before it is uſed, turning it over five or ſix times, that the parts may the better incorporate: and before it is uſed, it will be proper to paſs it through a ſcreen, to ſeparate the large ſtones, clods, &c. therefrom.

Having prepared the earth, and your cuttings being in a fit order for planting, you muſt fill as many halfpenny pots with earth as you have cuttings to plant; then put one cutting in the middle of each pot about two or three inches deep or more, according to their ſtrength; then give them a little water to ſettle the earth cloſe about them, and ſet the pots in a warm ſhady place for about a week, to prepare the cuttings for putting forth roots; after which they ſhould be plunged into a moderate hot-bed of tanners bark, which will greatly facilitate their rooting: but obſerve to give them air, by raiſing the glaſſes at all times when the weather will permit, as alſo to ſhade the glaſſes in the heat of the day.

In about ſix weeks or two months time after planting, theſe cuttings will be rooted, when you muſt begin to expoſe them to the open air by degrees, firſt drawing the pots out of the tan, and ſetting them on the top, then raiſe the glaſſes very high in the day-time; and in about a week after remove the pots into a green-houſe, and there harden them for another week; after which they may be expoſed to the open air in a well defended place, obſerving not to ſet them in a place too much expoſed to the ſun, until they have been inured to the open air for ſome time.

In this place the plants may remain until the beginning of october, at which time you ſhould remove them into the conſervatory, placing them as near the windows as poſſible at firſt, letting them have as much free open air as the ſeaſon will permit, by keeping the windows open whenever the weather is good; and now you muſt begin to abate your waterings, giving it to them ſparingly; but you ſhould not ſuffer their leaves to ſhrink for want of moiſture, which is another extreme ſome people run into for want of a little obſervation: for when they are ſuffered to ſhrink for want of ſufficient moiſture to keep their veſſels diſtended, they are rendered incapable of diſcharging this moiſture whenever they receive it again. The 14th ſort ſhould be placed in a moderate ſtove in winter, nor muſt it be ſet abroad till midſummer, for it is much tenderer than any of the others.

The beſt method to treat moſt of theſe plants is, to place them in an open, airy, dry glaſs-caſe, among Ficoideſes and African Houſeleeks, where they may enjoy as much of the ſun-ſhine as poſſible, and have a free, dry, open air; for if theſe are placed in a common green-houſe among ſhrubby plants, which perſpire freely, theſe ſucculent plants imbibe too much of the damp air, and thereby becoming too replete with moiſture, often caſt their leaves, and ſometimes their branches decay, and the whole plant periſhes.

3. This ſort requires a very ſhady ſituation, for if it be expoſed to the ſun in ſummer, the plants will ſoon decay. It is propagated by off-ſets like the Houſeleek; and requires a pretty ſtrong ſoil.

5, 6, 7. If theſe ſorts be ſown upon a wall, they will thrive better than in the ground, and be leſs liable to ſuffer by froſt; ſo that where the ſeeds ſcatter themſelves on walls or rock-work, the plants thrive better than when they are cultivated.

14, 15. Theſe ſorts require a warm ſtove to preſerve them through the winter in England, nor ſhould they be expoſed abroad in ſummer; for if they receive much wet, the ſtalks are very ſubject to rot; ſo that they ſhould conſtantly remain either in the ſtove, or in ſummer ſhould be placed in an airy glaſs-caſe with other tender ſucculent plants, where they may have free air in warm weather, and be ſcreened from cold and wet; but in autumn they muſt be removed into the ſtove, where they ſhould be kept in a moderate temperature of warmth: theſe are propagated by cuttings, which ſhould be taken off in ſummer, and planted into ſmall pots, and plunged into a moderate hot-bed, and when they have taken root, they ſhould be removed into the ſtove. They muſt have but little water, eſpecially in winter.

DESCRIPTIONS, *&c.*

1. The roots creep under ground, whereby it propagates very faſt. [The whole plant is ſmooth. The lower leaves are petioled, very large and ſpreading on the ground, varioufly waved, jagged and indented; ſmooth, glaucous, ſometimes tinged with purple: many ſtalks ariſe among theſe, two feet high, ſpreading and much branched, bearing ſimilar, but leſſſite leaves. The flowers on long peduncles, white. Fruit at firſt ovate, terminated by the blunt ſtigma, afterwards nearly ſpherical: the ſize of large Peas [a].

On the ſandy and beachy coaſts of Sweden, Denmark, Britain: as at Rooſebeck in Low Furneſs, Lancaſhire; near Megavilſey, in Cornwall; between Whitſtable and the iſle of Thanet; near Colcheſter; about Lyde in Kent, and elſewhere on the Eſſex and Kentiſh ſhores; thoſe of Suſſex and Dorſetſhire in great plenty, and elſewhere: flowering in may and june.

The young leaves, covered up with ſand, and blanched, are boiled and eaten as a great delicacy [b]. When full grown, they are ſaid to occaſion giddineſs. All ſorts of cattle eat them.

There is one variety with jagged leaves, and another with yellowiſh bloſſoms [c].

β. The ſeeds of this were ſent me from Peterſburgh for the common ſort, from which it differs greatly. This has a perennial root, which ſends out ſeveral oblong, ſmooth, pointed leaves, irregularly cut on their ſides into acute ſegments almoſt to the midrib; theſe are very ſmooth, and of a ſea-green colour: between theſe ariſes the ſtalk, which grows three feet high, garniſhed below by oblong pointed leaves, which are acutely indented on their edges. The ſtalks branch out into many ſmaller, and theſe ſubdivide again into leſs, which have looſe ſpikes of white flowers like thoſe of the common ſort, which are ſucceeded by ſeeds of the ſame form. This differs greatly from the firſt in the ſhape of its leaves, which are longer, ending in points, and the ſegments do the ſame; whereas thoſe of the other are blunt, and not half ſo deeply cut. The ſtalks riſe more than twice the height of the firſt, branch out more, and the branches grow more erect; and theſe differences are conſtant, where the plants of both ſorts grow in the ſame ſoil.

2. This has a biennial root, from which ariſe many leaves in the ſpring, that are alternately divided to the midrib; and theſe diviſions are again alternately cut on their edges into many points, ſo that they have the appearance of pinnate leaves, and are of a grayiſh colour. Stems two feet high, branching, terminated by looſe panicles of ſmall white flowers, coming out in june. The ſeeds ripen in autumn. Native of the Levant.

3. [Root whitiſh, annual, fuſiform. Stems very branching, angular, near three feet high, rugged, with ſtiff pungent reflex hairs, and terminating in wand-like racemes, the firſt quite ſimple and very long, the following ones branched. Leaves roundiſh, veined, wrinkled, ſomewhat rugged, unequally toothrepand, on angular petioles, having a ſingle appendix on each ſide at top; one of theſe is frequently deficient, but ſeldom both. Flowers in corymbs; calyxes yellowiſh; petals white. Fruits brown, ſhining, placed on a cylindric barren body, in which there is no trace of a cell, and this on a peduncle an inch in length [d].] It flowers in june, and the ſeeds ripen in autumn. Native of Spain and Italy.

[Cultivated 1759, by Mr. Miller [e].

4. Root perennial, fuſiform, as thick as the human arm, from two to four feet long, round, brown or blackiſh on the outſide when freſh, within fleſhy, white, with a tinge of dirty yellow, of a ſweet taſte. Stem from two to three feet high, angular, upright, ſmooth, branched. The root-leaves that firſt come out are often ſmall and entire; but afterwards theſe with the leaves on the ſtem and branches are diverſely and irregularly multifid, ſometimes very large, decompoundly or ſuperdecompoundly pinnatifid, dividing finally into oblong toothed ſharp ſegments, ſomewhat glaucous, ſmooth on both ſides, the upper ones are ſimple and oblong. Petioles angular, in the larger leaves ſmooth; but in the ſmaller ones, both theſe and the ribs are very thick and protuberant; they and the veins being ſomewhat hiſpid, with whitiſh hairs. The leaves, however, vary extremely in form and hairineſs, not only in different plants, but in the ſame individual. Flowers very numerous in terminating branched corymbs, ſmelling ſtrong of honey. Calyx greeniſh yellow. Petals white. Anthers greeniſh. Germ green, with a yellow ſtigma. Fruit the ſize of a pea, with a green ſhining fleſhy ſkin, becoming wrinkled and pale as it ripens. Seed blackiſh on the outſide: kernel pale yellow, with a ſubacrid and rather unpleaſant taſte.

[a] Woodw. Mſſ. & Lightf.
[b] Lightf.
[c] Withering.
[d] Hort. kew.
[e] Jacquin.

It

It flowers about the middle of april, and the fruits ripen in june, but few of them come to maturity.

Native of Hungary, Tartary, Moravia, and Bohemia. First noticed and described by Cluſius, who received it from Balthaſar de Bathyan, for the botanic garden at Vienna. Profeſſor Jacquin procured it again from Hungary in 1777.

The roots are eaten in a ſcarcity of bread by the Tartars and Hungarians; the hares alſo are very fond of them [f].

According to Jacquin, this is the Crambe orientalis of Linneus, and the fifth ſpecies of Royen; but probably not Rapiſtrum orientale acanthi folio of Tournefort, which is the true Crambe orientalis; and is deſcribed in obſ. bot. in the ſecond volume of Jacquin's miſcellanea, p. 337.

5. A ſtiff ſhrub, with leafy branches. Leaves alternate, petioled, deeply toothed, pinnatifid, or pinnate, with the diviſions ſerrate: hoary. The branchlets terminate in a large, diffuſed panicle, with alternate, divaricate, racemed branchlets; the racemes ſhort [g].

It approaches nearer to the character of Myagrum than of Crambe; for the filaments are not forked, and the ſilicles are almoſt two-jointed. The two genera might be very well united, and this removed to the order Siliculoſa [h].

Found by Maſſon, in the higheſt rocks of the iſland of Madeira [i].

Introduced 1777. It flowers moſt part of the year [k].

6. This is a rugged ſhrub. Stem erect, round, looſely branched, aſh-coloured, the height of a man. Leaves alternate, oblong-ovate, either undivided or eared, obliquely ſubcordate, acuminate, unequally toothed, wrinkled, nerved, bright green on both ſides, ſpreading, reclined: petioles round on one ſide, channelled on the other, ſtrigoſe. Panicles terminating, very long, compoſed of alternate compound racemes, peduncled, divaricate. Flowers pedicelled, erect, white. The leaves are four times as big as thoſe of C. fruticoſa, not hoary; and the ſtrigæ are ſtronger, but more lax [l].

Found in the Canary iſlands by Maſſon. Introduced 1779. It flowers in may and june [m].]

PROPAGATION AND CULTURE.

1. As this generally grows upon the gravelly ſhore, where the tide overflows it, the inhabitants obſerve where the gravel is thruſt up by the ſhoots of this plant, open it, and cut the ſhoots before they come out, and are expoſed to the open air, whereby the ſhoots appear as if they were blanched; and when they are cut ſo young, they are very tender and ſweet; but if they are ſuffered to grow till they are green, they become tough and bitter. This plant may be propagated in a garden, by ſowing the ſeed ſoon after it is ripe, in a ſandy or gravelly ſoil, where it will thrive exceedingly, and increaſe greatly by its creeping roots, which will ſoon overſpread a large ſpot of ground, if encouraged; but the heads will not be fit to cut until the plants have had one year's growth: and in order to have it good, the bed in which the plants grow ſhould, at michaelmas, be covered over with ſand or gravel about four or five inches thick, which will allow a proper depth for the ſhoots to be cut before they appear above ground; and if this is repeated every autumn, in the ſame manner as is practiſed in earthing of Aſparagus-beds, the plants will require no other culture. This may be cut for uſe in april and may, while it is young; but if the ſhoots are ſuffered to remain, they will produce fine regular heads of white flowers, which appear very handſome, and will perfect their ſeeds, by which they may be propagated.

[We are obliged to the Rev. Mr. Laurents for a more particular account of the culture of Sea Colewort or Sea Cale, which he obtained from the Weſt of England.

Prepare the bed intended to receive the ſeeds as for Aſparagus. Sow them in march. Before they are put into the ground, bruiſe the outer coat without wounding the ſeeds, to accelerate their growth. Set three ſeeds in a triangular form ſix inches apart, leaving a ſpace of two feet between the triangles. Bury the ſeeds three inches deep.

The plants will make their appearance in four or five months, but they ſhould not be cut until the third ſpring. About the end of november, when the leaves are rotten, clear them away, and cover the bed with a coat of half rotten dung.

In the ſecond year, about march, when the plants are beginning to perforate the ſurface, take or rake off lightly the coat of dung, and give the plants full liberty to grow. In november, or ſooner if the leaves be rotten, clear them off, and cover as in the former year.

In the third year, immediately after removing the dung in the ſpring, cover the plants with a thick coat of ſand or coal aſhes, or ſmall pebbles. As they grow, continue to keep them from the air, until they are cut for uſe.

In cutting them, remove the ſand, aſhes or pebbles, and then cover the roots again. Some of the plants will bear cutting two or three times in a ſeaſon.

After the laſt cutting is finiſhed, remove the cover, and let the plants grow until the leaves are decayed; and then clear and cover for the winter.

Some cover their plants with earthen pans or large garden pots, putting a tileſherd over the hole, for all air muſt be ſecluded in order to have them white [n].

2. May be propagated in the ſame manner.

3. Muſt be propagated by the ſeeds.

[5, 6. Are inhabitants of the green-houſe. The others are hardy. The two laſt grow freely from cuttings.

Nat. order of *Perſonatæ.—Bignoniæ* Juſſ. 140.

GENERIC CHARACTER.

CAL. *Perianth inferior* four-leaved; *leaflets* linear, ſhort, ſpreading, permanent.
Perianth ſuperior ovate, inflated, large, cut lengthwiſe on one ſide.
COR. one-petalled, unequal; *Tube* very long, very narrow. *Border* flat, two-lipped; *upper lip* entire, roundiſh: like the other diviſions, but larger. *Lower lip* three-cleft; *diviſions* roundiſh; the middle one wider.
STAM. *Filaments* four, length of the tube of the corolla, of which two are ſomewhat ſhorter. *Anthers* ſimple.
PIST. *Germ* ovate. *Style* thread-form, length of the tube of the corolla. *Stigma* thickiſh, obtuſe.
PER. coriaceous, ovate, ſharp on both ſides, two-valved.
SEED. *Nut* woody, depreſſed, ſharpened on both ſides, with a bent two-parted point, marked on each ſide with three-toothed furrows, (of the figure of a quadruped's ſkull,) two-cleft on the ſides.
OBS. *This genus is too nearly allied to* Martynia, *but the corolla is more equal.*
In Cr. annua *the inferior calyx is two-leaved.* R.

ESSENTIAL CHARACTER.

Cal. double of the flower: perianth four-leaved; ſpathe one-leafed. *Cor.* tube very long.—*Capſ.* of Martynia.

SPECIES.

1. Craniolaria annua.
Lin. ſyſt. 558. *Reich.* 3. 141. *mant.* 417. *Jacqu. amer.* 173. *t.* 110. *amer. pict.* 86. *t.* 166. *Ebret. pict.* 1. *f.* 2.
Martynia Craniolaria. *Gloxin. obſ. bot.* p. 11. & 14.
Leaves cordate angled; outer calyx two-leaved.

DESCRIPTION, *&c.*

1. [This is an annual plant, two feet high, the whole of it villoſe and extremely viſcid, from a ſingle and very ſhort trunk divided into dichotomous, round thick branches, procumbent at the baſe, but above the middle erect, diffuſed. Leaves large, oppoſite, half five-lobed; the lobes ſubovate, repand-toothed, acute: petiole reddiſh, hairy, dividing at the end, and bordering the leaf on each ſide at the baſe. Racemes ſimple, looſe, upright, near a foot in length, and containing about ten flowers, in all the diviſions of the ſtem, accompanied by a ſolitary one-flowered peduncle. Other ſhorter irregular racemes terminate all the branchlets, and ſpring from the axils of ſome leaves. Flowers handſome, but without ſcent, hirſute. Calyx green. Corolla white, with three large dark purple ſpots at the bottom of the throat. There is a very ſhort rudiment of a fifth filament under the diviſion of the upper lip. Pericarp at firſt green, but yellow when ripe. Nut black, abiding ſome days after the pericarp has fallen, not opening, or even ſeparable with conſiderable force, though it appears to be four-valved. The proper peduncles are ſupported by a bracte reſembling the calycine appendicles. The throat of the corolla, which is more clammy than any part of the plant, generally has abundance of very ſmall flies, which are attracted by the honey juice, and being entangled in it, there meet their death [a].

Linneus obſerves, that the calyx is ovate, diſſected above longitudinally, and has two bractes at the baſe. It reſembles Martynia annua, but the tube of the corolla is very long [b]. (ſeven or eight inches.)

The root, which is brown without, but white within, round, fleſhy, thick, has a ſweet taſte, and is eaten freſh with milk, or preſerved with ſugar. It is uſed in the Spaniſh Weſt-Indies for the ſame purpoſes as that of Scorzonera is in Europe; and is called there by the ſame name [c].]

It was diſcovered in the neighbourhood of Carthagena in New Spain by William Houſtoun, M.D. who ſent the ſeeds to England.

PROPAGATION AND CULTURE. See MARTYNIA.

CRANIOLARIA. See *Geſneria* and *Martynia.*

CRANTZIA. See *Tricera.*

[CRANZIA. (*So named by Schreber in honour of Joa. Nepom. Crantz or Cranz, profeſſor of materia medica, &c. at Vienna, author of Stirpes Auſtriacæ, &c.*)

Lin. ſyſt. 306. *ſuppl.* 189. *Thunb. nov. act. nat. cur.* 6. 330. *Ait. hort. kew.* 396.
Leaves petioled cordate, flowers ſolitary.
Craſſula montana.
Lin. ſyſt. 307. *ſuppl.* 189. *Act. nov. nat. cur.* 6. 332.
Leaves connate ovate acute ciliate, ſtem almoſt naked, flowers headed-aggregate.
37. Craſſula mollis. *Fig-Marygold-leaved Craſſula.*
Lin. ſyſt. 307. *ſuppl.* 189. *Thunb. nov. act. nat. cur.* 6. 340. *Ait. hort. kew.* 391.
Leaves connate, cylindric-triquetrous, ſmooth, ſoft, remote; ſtem erect, ſimple; corymb trichotomous ſuperdecompound.
38. Craſſula crenulata. *Notch-leaved Craſſula.*
Lin. ſyſt. 307. *ſuppl.* 189. *Act. nov. nat. cur.* 6. 339.
Leaves connate lanceolate dotted and crenulate remote, corymb decompound.
39. Craſſula alpeſtris.
Lin. ſyſt. 307. *ſuppl.* 189. *Act. nov. nat. cur.* 6. 336. *t.* 56. *f.* 4.
Leaves connate ovate acute entire imbricate in four rows, heads peduncled.
40. Craſſula pyramidalis.
Lin. ſyſt. 307. *ſuppl.* 189. *Act. nov. nat. cur.* 6. 335. *t.* 56. *f.* 3.
Leaves connate ovate obtuſe entire imbricate in four rows, heads ſeſſile.

41. Craſſula ſpicata.
Lin. ſyſt. 307. *ſuppl.* 189. *Act. nov. nat. cur.* 6. 333.
Leaves connate linear-ſubulate, ſcape almoſt naked, flowers in whorls.
42. Craſſula turrita.
Lin. ſyſt. 307. *ſuppl.* 189. *Act. nov. nat. cur.* 6. 336.
Leaves connate imbricate in four rows ovate-oblong acute ciliate.
43. Craſſula rupeſtris.
Lin. ſyſt. 307. *ſuppl.* 189. *Act. nov. nat. cur.* 6. 337.
Leaves connate ovate entire ſmooth, ſtem covered, corymb ſuperdecompound.
44. Craſſula thyrſiflora.
Lin. ſyſt. 307. *ſuppl.* 190. *Act. nov. nat. cur.* 6. 339.
Leaves perfoliate ovate ciliate patulous, corymb compound ſpiked.
45. Craſſula capitella. *Square-ſpiked Craſſula.*
Lin. ſyſt. 307. *ſuppl.* 190. *Thunb. nov. act. nat. cur.* 6. 339. *Ait. hort. kew.* 394.
Leaves oblong connate cartilaginous-ciliate, patulous, flowers in headed whorls.
46. Craſſula pubeſcens.
Lin. ſyſt. 307. *ſuppl.* 190. *Act. nov. nat. cur.* 6. 340.
Leaves connate ovate-ſubulate villoſe, ſtem branching, flowers corymbed.
47. Craſſula cephalophora.
Lin. ſyſt. 307. *ſuppl.* 190. *Act. nov. nat. cur.* 6. 333.
Leaves connate linear-oblong obtuſe entire; heads lateral peduncled.
48. Craſſula tomentoſa.
Lin. ſyſt. 307. *ſuppl.* 190. *Act. nov. nat. cur.* 6. 333.
Leaves connate lanceolate villoſe ciliate, ſtem almoſt naked, flowers in whorls.
49. Craſſula Cotyledonis.
Lin. ſyſt. 307. *ſuppl.* 190. *Act. nov. nat. cur.* 6. 332.
Leaves connate oblong tomentoſe ciliate, ſtem almoſt naked, flowers corymbed aggregate.
50. Craſſula tecta.
Lin. ſyſt. 307. *ſuppl.* 190. *Act. nov. nat. cur.* 6. 331.
Leaves connate ovate obtuſe aſh-coloured lamelloſe, ſcape naked, flowers ſeſſile.
51. Craſſula perforata.
Lin. ſyſt. 307. *ſuppl.* 190. *Act. nov. nat. cur.* 6. 338.
Leaves connate-perfoliate ovate, ciliate, remote; ſtem erect, thyrſe-bearing.

Species from Hortus Kewenſis.

52. Craſſula expanſa. *Awl-leaved Craſſula.*
Ait. hort. kew. 390.
Leaves ſemicylindric-ſubulate channelled above ſpreading, peduncles axillary ſolitary one-flowered, ſtems dichotomous.
53. Craſſula lineolata. *Channelled Craſſula.*
Ait. hort. kew. 391.
Stem herbaceous, leaves cordate ſeſſile, peduncles almoſt terminating axillary approximating umbel-ſhaped.
54. Craſſula pulchella. *Reflex-leaved Craſſula.*
Ait. hort. kew. 392.
Stem herbaceous dichotomous, leaves ovate-oblong fleſhy reflex, flowers in the forks peduncled, peduncles turbinate.
55. Craſſula imbricata. *Imbricate Craſſula.*
Ait. hort. kew. 393.
Leaves ovate acute imbricate in four rows gloſſy, flowers axillary ſeſſile.]
56. Craſſula obliqua. *Oblique-leaved Craſſula.*
Ait. hort. kew. 393.
Cotyledon ovata. *Mill. dict. n.* 8.
Leaves oppoſite ovate oblique quite entire acute diſtinct, ſomewhat cartilaginous at the edge.
[57. Craſſula alooides. *Spike-flowered Craſſula.*
Ait. hort. kew. 394.

Leaves ovate diſtinct acute ciliate, ſtem ſimple, ſomewhat hairy, raceme compound, branches panicle-ſhaped.

58. Craſſula ſparſa. *Alternate-leaved Craſſula.*
Ait. hort. kew. 395.

Leaves alternate ſubſpatulate acute quite entire, raceme compound.

59. Craſſula diffuſa. *Diffuſe Craſſula.*
Ait. hort. kew. 395.

Leaves oblong attenuated at the baſe remotely crenate, peduncles oppoſite to the leaves and axillary ſolitary.

60. Craſſula ſpathulata. *Crenated Craſſula.*
Ait. hort. kew. 395. *Thunb. nov. act. nat. cur.* 6. 330.

Leaves petioled cordate-roundiſh acutiſh crenate, corymbs panicle-ſhaped.

61. Craſſula marginalis. *Margined Craſſula.*
Ait. hort. kew. 396.

Stem ſhrubby, leaves cordate perfoliate acuminate plane ſpreading dotted within the margin.

62. Craſſula lactea. *Snowy Craſſula.*
Ait. hort. kew. 396.

Stem ſhrubby, leaves ovate attenuated at the baſe connate quite entire dotted within the margin, cymes panicled-ſhaped.

63. Craſſula ceſpitoſa.
Cavan. hiſp. 50. *n.* 76. *t.* 69. *f.* 2.

Leaves globoſe-ovate, imbricate four ways, cyme three-flowered, flowers ſeſſile.

64. Craſſula Umbella.
Jacqu. collect. 4. 172. *icon. rar.* 2.

Leaves roundiſh perfoliate, racemes axillary and terminating, upper peduncles in whorls.]

DESCRIPTIONS, *&c.*

1. Stem reddiſh, jointed, about three feet high, dividing at top into many irregular branches. Flowers at the ends of the branches, in cloſe umbels. Corolla funnel-ſhaped, erect, with a pretty long tube cut at the top into five parts, of a fine ſcarlet colour.

[Leaves ſo cloſely oppoſite, as to appear to be in four rows. Faſcicle terminating twice dichotomous; flowers ſeſſile, alternate, monopetalous with a five-parted border[a]. Introduced 1714, by Profeſſor Richard Bradley[b].

It flowers in july or auguſt.

2. Stems a ſpan high, erect, ſmooth, annual; roots perennial. Leaves oppoſite, ſmooth, cartilaginous-ſcaly about the edge. Cyme ſmall[c], bifid; denſe, ſcaly[d].

3. Stem erect, like that of *C. coccinea*, perfoliate, but the leaves not ciliate. Flowers faſcicled, but each pedicelled; petals yellow, erect[e].

4. A ſhrub of a foot in height, dichotomous, the ſmall branches round, blood-red, covered as is the whole plant with the reſemblance of a cryſtalline hoar-froſt. Leaves oppoſite, linear, fleſhy, plane above, the length of the internodes, obſcurely connate. Corymbs terminating, unequal, ſmall. Petals white, lanceolate, ſpreading[f].]

5. Stem weak, ſucculent, about a foot and half high, dividing at top into ſmall branches. Leaves flat, near two inches long, and a quarter of an inch broad at their baſe, gradually narrowing to a point. Flowers in ſmall cluſters at the ends of the branches, ſmall and herbaceous.

[Stem reddiſh green, with age becoming of a cheſnut colour. Leaves thick, ſucculent. The ſtem and leaves are every where rough with whitiſh bubbles. The corolla is ſo deeply divided, as to leave a doubt whether it be monopetalous or pentapetalous[g].

It flowers in june and july.

Cultivated by Dr. Sherard at Eltham, between 1724 and 1732. About the ſame time in the Chelſea garden.]

6. This riſes with an upright ſtem ten or twelve feet high, if it be not broken or injured, but it requires ſupport, the ſtems being ſlender, and the leaves very weighty. The latter are about three inches long, thick, ſucculent, pale green, acute, hollowed above, and having a convex ridge beneath. Flowers terminating, in large cluſters, of a whitiſh herbaceous colour, with ſhort tubes, and the brim cut into five parts. The flower-ſtalk is thick and ſucculent, generally turning firſt downwards, then upwards again, almoſt in form of a ſyphon. It flowers in july, but does not produce ſeeds here.

[Cultivated in 1725 at Eltham, by Dr. Sherard[h].

7. The ſtature of this approaches to that of *C. tetragona*, but it differs, in having the ſtem only a foot high (not three or four feet), erect, green, not reddiſh: the branches narrow almoſt filiform. Leaves oppoſite, horizontal, oblong, columnar, acuminate, not depreſſed above, but rather underneath, and a little arched backwards, ſo as to reſemble *Salſola fruticoſa*[i].

8. Leaves the thickneſs of a gooſe quill. Peduncle terminating, naked, columnar. Cyme trifid, very much branched, faſtigiate. Corolla white with purple anthers[k].

Introduced 1714, by Richard Bradley, Profeſſor of Botany at Cambridge[l].

9. Root perennial. Stem fruteſcent, filiform, branched at bottom, leafy, ſmooth, a foot high. Branches alternate, long, gradually attenuated, ſmooth, rufeſcent. Leaves faſtigiately-oppoſite, columnar-ſubulate, longer than the internodes, entire, ſmooth, the upper ones gradually ſmaller. Flowers in narrow compound corymbs[m].

Introduced 1774. It flowers in july and auguſt[n].

10. This reſembles very much the next ſpecies, and is very nearly allied to the thicker ones on account of the flowers, the petals of which are white and ſpatulate, awned at the top with a globe, as in the *cultrata*, and never unfolding: but it differs in having a ſhorter ſtem, only a palm in height, and ſpreading; leaves twice as long and larger, not at all contracted at the baſe, more oppoſite and crowded, not having any ſpace between them, the edges, eſpecially of the young ones, very finely crenulated and by no means oblique as in that[o].]

11. This ſort riſes with a weak ſucculent ſtalk about two feet high, ſending out many irregular branches. Leaves thick, plane above but convex beneath, deep green, the borders ſet with a few ſilvery hairs. The ſtalk which ſupports the flowers riſes from the top of the branches, and is from four to ſix inches long, putting out ſeveral ſide branches, which grow erect; theſe are terminated by large cluſters of ſmall greeniſh flowers, which appear in june and july.

[The flower never expands.—Cultivated in the Eltham garden 1732, or earlier[p].

12. The whole plant is ſmooth. Stem as thick as the wriſt, round, browniſh; branches round, greeniſh brown: both are jointed, the joint above blunt and entering the cavity of that below it. Leaves diſtinct, oppoſite, ſubſeſſile, ſpatulate, rounded, quite entire, ſpreading, glaucous, ſpotted on the upper ſide only with great numbers of dark green ſpots, and having a deep border of purple on the edge; ſome are very blunt, others have a very ſmall point. Cymes dichotomous, terminating on almoſt all the branchlets. Peduncles compreſſed, greeniſh-glaucous. Bractes ſmall at the diviſions of the peduncles. Flowers numerous, without ſcent. Perianth ſmall, glaucous, ferruginous-red at the end. Petals lanceolate, large, flat, acute, having no claws, but ſpreading very much above the calyx, at firſt white, afterwards roſe-coloured. In the flowers of the principal dichotomies one-fifth part is commonly wanting in all parts of the fructification, ſo that the plant would at firſt flowering ſeem to belong to the fourth order of the fourth claſs[q].

Cultivated in 1739.

[a] Dillenius. [b] Linn. mant. [c] Ibid. [d] Hort. kew. [e] Thunberg. [f] Hort. kew. [g] Linn. mant. [h] Dillenius. [i] Jacquin.

[k] Linn. mant. [l] Hort. kew. [m] Linn. mant. [n] Bergius. [o] Linn. mant. [p] Ibid. [q] Mart. cent.

In the laſt edition of the Dictionary (1768), Mr. Miller ſays it had not then flowered in England. It flowered in the Imperial garden at Vienna in 1778, at the end of april.

13. A ſhrub, browniſh red, even, with alternate branches. Leaves unequally, alternate: leaflets petioled, cordate, quite entire, acute, even, ſeven or nine; petioles thickiſh at the baſe. Panicle axillary, ſhorter than the leaves, red. Flowers red.—Native of China[r].

14. Stem roundiſh, brachiate, ſomewhat pubeſcent. Leaves generally oppoſite, fleſhy, acute, ſhining, with excavated dots on the upper ſurface. Annual[s], *or* Biennial. Flowering in may and june Introduced 1774, by Mr. Francis Maſſon[t].

15. This is ſcarcely a palm in height. Stem ſimple, round, pale green, dichotomous at top. Leaves oppoſite, not unlike thoſe of the leſſer Centory. Flowers purple on the outſide, golden-coloured within, with a blood-red heart-ſhaped ſpot at the bottom of each petal[u].

Annual. Flowering in june and july. Introduced 1774, by Maſſon[x].

16. Stem a palm in height, erect, round, purpliſh. Leaves oppoſite, fleſhy, ſeſſile, ſpreading very much, ſharpiſh. Flowers from the forking of the ſtem, ſolitary, ſubpeduncled. Flowers terminating the branchlets, crowded into heads. Diviſions of the calyx ovate, convex, from erect patulous. Petals ovate, white, one-third only of the ſize of the calyx, and therefore minute. Stamens only half the length of the petals. Piſtils five, with ſcarcely any ſtyles, ſtigmas ſhorter than the ſtamens.—The leaves every where ſubciliate at the baſe.—The plant when mature growing reddiſh, except the petioles. Annual[y].

It is commonly deſcribed as having a rough ſtalk; this however is ſometimes ſmooth. It flowers in june and july. Introduced 1774, by Maſſon[z].

17. Leaves oppoſite, obtuſe, marked with lines, quite entire, the lower often on petioles. Calyxes ſtrigoſe, petals ovate, the length of the calyx[a].

18. Stems filiform, ſeldom branched, covered with very ſmall, ſeſſile, fleſhy, bluntiſh leaves. Flowers the moſt minute of all, the length of the leaves[b].

19. Leaves like thoſe of Houſeleek, only ſomewhat ſmaller and more obtuſe, thickly fringed about the edge with white hairs. Stems ſhort, ending in a few leafy branches, which are elongated into round ſhoots a long ſpan in length, having leaves on them like the lower ones, but diſtant from each other in pairs; theſe are generally divided into two peduncles ſuſtaining yelloviſh flowers[c].

Perennial. Flowering in july and auguſt. Cultivated 1732, by Dr. James Sherard, at Eltham[d].]

20. Stems very ſlender, full of joints, trailing. Leaves thick, ſucculent, heart-ſhaped, connate, grayiſh. The ſtems are divided, grow about eight or nine inches long, and are terminated by cluſters of ſmall white flowers, ſitting very cloſe to the top: theſe appear in ſpring, and again in the latter part of ſummer.

[Stem round, even, ſimple. Leaves in a double row, ſeſſile, hollow-dotted, convex underneath, very tenderly ciliate. Corymbs axillary, very ſhort, faſtigiate. Corollas bell-ſhaped, with a reflex border. Anthers purple[e].

Cultivated 1759, by Mr. Miller[f], who received it from Adrian van Royen.

21. Stem covered with truncate, ciliate ſheaths of leaves. Leaves linear, fleſhy, obtuſe, cartilaginous-ciliate. Spikes headed, terminating, ſubſeſſile with an imbricate involucre. Annual[g].

22. Branches two feet long, lax, purple, hairy. Leaves drawn to a very long point at the end, ſeſſile. Flowers ſolitary, on ſhort peduncles, yellow[h].

23. Stem round, pubeſcent, decumbent. Branches aſcending, a finger's length. Leaves ſeſſile, the thickneſs of a hen's feather, towards the end a little attenuated, and there red; the lower almoſt an inch in length, the upper gradually ſhorter. Flowers in the branches among the leaves, ſcattered, remote, on very ſhort peduncles. Leaflets of the calyx fleſhy, convex on the outſide, ſomewhat villoſe, a line in length. Petals three times the length of the calyx, white, keeled; the keel ſomewhat villoſe and red. Nectaries white, very ſmall. Filaments a little ſhorter than the petals. Anthers roundiſh, ſmall, red. Annual[i].

Stem ſimple, with a few viſcid hairs. Leaves ſpreading, oblong, obtuſe, fleſhy; the lower in fours. Cyme trifid or quadrifid with recurved branches. Flowers ſeſſile. Stamens reflex. In ſtature it reſembles Sedum annuum[k]. Branches red, bifid, trifid or multifid at top. Leaves alternate. Stamens ten, but five of them ſoon withering[l].

Stem one, uſually branched; branches erect, generally ſimple. Leaves oblong, ſemicolumnar, linear, flattiſh above, aſh-coloured with a red tip. When viewed with a glaſs very finely hirſute, eſpecially thoſe of the ſtem. The whole branches flower-bearing; the flowers ſeſſile, not really in the axils of the leaves, but placed a little above at their ſides. Leaflets of the calyx ovate, acute. Petals lanceolate, awned. Stamens five. Fruit ſtellate, red, compoſed of the five little capſules awned with the permanent ſtyle[m].

Native of Switzerland and Italy. With us it flowers in may and june. Cultivated 1759, by Mr. Miller[n].

24. Stem very much branched, diffuſe, branches oppoſite, the length of a finger. Leaves oppoſite, crowded, oblong-ovate, ſeſſile, gibbous, with very minute pimples, ſcabrous at the end. Flowers axillary, ſeſſile, very minute. Calyx the length of the corolla, ſubulate. Petals ſhorter than the calyx, lanceolate, acuminate ſo as to be almoſt awned, red in the middle. Stamens very ſhort, red at the end. Stigmas red. Annual[o].

It flowers in july. Introduced 1778, by Mr. Zier[p]. Native of Southern Europe.]

25. This never riſes with a ſtalk, but the leaves come out cloſe to the ground, forming a ſort of head. They are ſucculent, taper, ending in points, and frequently put out roots: out of the centre of theſe ariſes the flower-ſtalk, branching into two or three ſhoots at top, each terminated by cluſters of greeniſh flowers, which make no great appearance.

[Leaves ſmooth, ſomewhat hoary, not unlike thoſe of the Pink, only thicker, and ſet with excavated dots. Flower-ſtems round, from four inches to a foot in height, with joints having each four leaflets. The flowers do not open.

This ſpecies has been long known in the gardens of the curious[q].] It flowers in may, and ſometimes again in the latter part of ſummer.

26. This is a low plant, having open ſpreading heads very like thoſe of ſome ſorts of Houſeleek, growing on the ends of very ſlender trailing ſtalks, produced in plenty on every ſide the parent plant, in like manner as the childing Marigold. The flower-ſtalks ariſe from the centre of theſe heads; they are naked, about four inches long, and terminated by cloſe cluſters of herbaceous flowers. Leaves radical, forming roſes, ovate, fleſhy, gibbous, even, ſharpiſh, ciliate backwards with cartilaginous, very ſlender hairs. The root puts forth lateral threads, which are filiform and decumbent, forming runners at the end. Scape hardly longer than the leaves, and erect. Spike brachiate-verticilled, with few flowers. Petals whitiſh red. Stigmas purple. Perennial[r].

It flowers uſually in july and auguſt, ſometimes in may[s].—Cultivated 1732, by James Sherard, M. D.[t]

27. Stems ſlender, trailing, ſucculent, of a reddiſh colour, and putting out roots at the joints.

[q] Dillenius. [r] Linn. mant. [s] Dillenius. [t] Hort. kew.

Theſe and the leaves have the appearance of Purſlane. The flowers are produced in ſmall cluſters at the ends of the branches; they are white, with a bluſh of purple at the brim; they appear in ſummer at different times, and are often followed by ſeeds.

[Common in botanic gardens, both in England and abroad[a].

28. Stem round, ſmooth, covered with leaves. Leaves ſmooth. Flowers terminating, very copious, white; head hemiſpherical[z].—Leaves very blunt, horizontal. Border of the corolla linear, ſpreading[y].

This, and all the foregoing ſpecies, are natives of the Cape of Good Hope, except a very few, the places of growth of which are ſet down.

29. Root biennial. Root-leaves very many, aggregate, thin, ſmooth, with bundles of hairs at the edge. Stem-leaves only two pairs, like the others, but much leſs, and remote. Stem ſlightly angular, erect, ſmooth, a ſpan high, nearly the thickneſs of a quill[x].

30. Root perennial. Stem ſhrubby, branched, a foot or more in height: branches round, ſmooth. Leaves oppoſite, ſuborbiculate, from ſpreading upright, fleſhy, thick, blunt with a point, and with a ſharp edge. Flowers terminating, in an ovate corymb[w].

31. Root fuſiform, creeping, perennial. Stem almoſt upright, branched, a palm high, naked at the baſe. Branches and branchlets alternately ſcattered. Leaves alternately oppoſite, very gibbous underneath, quite entire; the upper ones very cloſe, with a white meal on them, and minute green ſpots; the lower ones ſhrivelling; imbricate in four rows. Flowers ſeſſile, yellow[v].

32. Root fuſiform, perennial. Stems ſeveral, radical, filiform, dichotomous-branched, upright: branches alternate, upright, divided, faſtigiate. Leaves on the branches and branchlets faſtigiately oppoſite, ſeſſile, diſtinct, ſuborbiculate, fleſhy, thickened at the tip, entire, green at the baſe, mealy at the tip, white, with impreſſed greeniſh dots in four rows, frequent, longer than the internodes. Flowers from the ends of the branchlets, very many, terminating, upright, peduncled. Peduncles filiform, ſmooth, one-flowered, ſcarcely longer than the leaves[u].—This and the foregoing reſemble ſea Corallines in the ſtructure of the leaves, but are larger[t].

33. Root annual. Stem filiform, flexuoſe-erect, a finger's length, ſmooth, purple. Stem-leaves two or four, ovate-lanceolate, blunt, ſpreading, entire. Flowers erect, in a decompound, ſubdichotomous cyme. Peduncles and pedicels capillary, with oppoſite bractes under them, like the leaves, but ſmaller. There are three varieties—

1. With orange-coloured flowers, larger.
2. With yellow flowers, middle-ſized.
3. With white flowers, ſmaller and more tender[s].

34. Stem herbaceous, fleſhy, round, upright, naked at bottom, leafy above, branched. Leaves alternately oppoſite, imbricate, ſpreading at the tip, entire, glaucous, mealy. Flowers in a terminating, compound, ſubfaſtigiate corymb[r]. The leaves have the ſame form with thoſe of Meſembryanthemum deltoideum[q].

35. Root annual. Stems herbaceous, weak, gradually more ſlender, leafy at bottom, branched at top, fleſhy, round, fleſh-coloured, almoſt upright, a palm in height: branches oppoſite, capillary, from ſpreading upright, ſmooth. Stem-leaves faſtigiately oppoſite, round, entire, from reflex ſpreading, thick, fleſhy, green, rufous on the edge and dotted with the ſame colour: branch-leaves ſimilar, but many times ſmaller and thinner, green with a circle of dots within the edge. Flowers terminating, on capillary peduncles, a line in length[p].

Introduced at Kew in 1774, by Maſſon. It flowers from may to auguſt[o].—At the Cape, in november and december[n].

[a] Dillenius. [b] Ibid. [c] Thunberg. [d] Ibid. [e] Thunberg. [f] Ibid. [g] Linn. ſuppl. [h] Thunberg. [i] Hort. kew. [k] Thunberg. [l] Linn. ſuppl. [m] Thunberg. [n] Hort. kew. [o] Thunberg. [p] Ibid. [q] Ibid. [r] Ibid. [s] Ibid. [t] Ibid. [u] Ibid. [v] Ibid. [w] Ibid. [x] Ibid. [y] Hort. kew. [z] Thunberg.

36. Root-leaves concave, very frequent, patulous, ſmooth, green tinged with purple; ſtem-leaves about three pairs, ſimilar but ſmaller and remote. Stem filiform, upright, a finger's length, purple. Flowers ſeſſile, in heads uſually ſolitary, ſeldom two lateral together[l].

37. Root perennial. Stem frutescent, angular, ruſeſcent, very finely tomentoſe, jointed, almoſt the thickneſs of a quill, a foot high. Leaves acute, ſmooth or very finely ſubtomentoſe, patulous; the lower ones nearer, the upper more remote. Flowers in a ſubfaſtigiate corymb. Bractes two, oppoſite, below the peduncles and pedicels, like the leaves but ſmaller[m].

Introduced in 1774, by Maſſon. It flowers here in auguſt[k]; at the Cape in january.

38. Stem herbaceous, upright, cylindric, leafy, jointed, ſmooth, green variegated with white lines, the thickneſs of a quill, a foot high. Leaves faſtigiately oppoſite, ſeſſile, ſubconnate, linear lanceolate, obtuſe, concave above, convex beneath, ſmooth, longer than the internodes, a finger's length, upright but ſpreading at the tip; the upper ones gradually ſmaller and more remote. Flowers white, in a trichotomous, faſtigiate corymb. Two oppoſite, minute bractes under each pedicel[j].

39. Stem round, ſmooth, upright, branched at bottom, before flowering time wholly covered with leaves, a palm high, purple. Branches radical, one or two, ſhort. Leaves acuminate, concave, entire, purpliſh green. Flowers in ſeveral terminating heads, which are larger than Peas. Peduncles purple.

It reſembles C. montana, but the leaves are more acuminate and not ciliate; the ſtem thicker and covered with leaves; the heads and flowers larger[i].

40. Root perennial. Stem flexuoſe-erect, branched, the whole covered with leaves, a palm high; branches alternate. Leaves margined, a line long, ſmooth. Flowers at the ends of the branches, in ſolitary globular heads, larger than a pea.

It reſembles C. muſcoſa, but has a thicker ſtem, and the flowers in heads[h].

41. Root-leaves faſtigiately oppoſite, erect, concave above, convex below, ſmooth, a finger's length, very much crowded; ſtem-leaves oppoſite, ſmaller. Stem round, herbaceous, erect, ſmooth, a ſpan high. Whorls approximating, ſeſſile, many-flowered[g].

42. Root annual. Stem herbaceous, weak, erect, round, jointed, covered with leaves, ſmooth, a palm high. Branches, when there are any, axillary, very ſhort. Leaves alternately oppoſite, cartilaginous-ciliate, thick, ſmooth, red; the lower ones oblong, concave above, convex beneath; the upper ones ovate, flat above, convex beneath; the uppermoſt gradually ſmaller and nearer[f].

43. Root perennial, branched. Stem round, branched, a palm and more in height. Leaves alternately oppoſite, acute, a little concave above, convex and keeled beneath, approximating, longer than the internodes, green with a ruſeſcent margin, from erect patulous. Flowers in trichotomous faſtigiate corymbs. Peduncles and pedicels ſmooth; white tinged with purple. There is a minute, ovate, white bracte under each pedicel[e].

44. Stem round, herbaceous, upright, a ſpan high, ſmooth. Leaves obtuſe, ſhorter than the internodes, ſmooth. Flowers white, in a thyrſe gradually attenuated, decompound, a palm in length. Bractes below the peduncles and pedicels, oppoſite, like the leaves but ſmaller[d].

45. Stem round, ſmooth, erect, a ſpan high, the thickneſs of a quill, ſometimes branched at top. Leaves acute, ciliate, remote, longer than the internodes, ſmooth. Flowers white, in ſeſſile, many-flowered, approximating whorls[c].

It was introduced in 1774, by *Maſſon*; flowers in july and auguſt; and is biennial[b]. At the Cape it flowers in december and january.

[a] Thunberg. [b] Ibid. [c] Hort. kew. [d] Thunberg. [e] Ibid. [f] Ibid. [g] Ibid. [h] Ibid. [i] Ibid. [j] Ibid. [k] Hort. kew.

46. Root perennial. Stem filiform, frutescent, branched, erect, red, ſmooth, a ſpan high: branches ſubverticillet in threes, ſubdivided, pubeſcent. Leaves thick, ſpreading, the length of the internodes, flattiſh above, gibbous beneath. Corymb compound, trichotomous [z].

47. Root-leaves erect, ſubtomentoſe, a finger's length: ſtem-leaves none. Stem round, erect ſubtomentoſe, a ſpan high. Heads of flowers oppoſite, the ſize of a pea [a].

48. Root-leaves bluntiſh, hirſute, imbricate; ſtem-leaves three pairs, ſmaller. Stem angular, erect, villoſe, a foot high [b].

49. Stem ſimple, erect, herbaceous, ſlightly four-cornered, leafleſs, tomentoſe, the thickneſs of a quill, a foot high. Root-leaves ſeveral, faſtigiately-oppoſite, very much crowded, oval, obtuſe, flat above, convex beneath, entire, ſubtomentoſe and ſoft, a finger's length, an inch wide, erect; ſtem-leaves three pairs, ſmaller. Bractes on the peduncles faſtigiately-oppoſite, connate-ſheathing, ovate, obtuſe, preſſed cloſe, a line in length, tomentoſe. Flowers white, pedicelled. Peduncles trichotomous. Corymb decompound [c].

50. Stem ſcarcely any. Leaves ſubradical, very abundant, imbricate, convex beneath, concave above, thick, covered with an aſh-coloured meal reſembling the ſcales of a butterfly's wing, naked at the baſe, cartilaginous-ciliate; the upper ones ſmaller. Scape erect, filiform. Flowers ſeveral, minute, collected into a head [d].

51. Stem round, jointed, gradually attenuated, leafy, ſmooth, a foot high. Leaves faſtigiately-oppoſite, acute, cartilaginous-ciliate, ſpreading, the length of the internodes, green, underneath and on the upper edge ruſeſcent. Flowers in an interrupted compound thyrſe, chiefly directed one way, and bent in. Peduncles and pedicels filiform [e].

This, and all the foregoing ſpecies from twenty-nine incluſive, are natives of the Cape of Good Hope, and were obſerved there by Thunberg.

52. Annual. Flowering in june and july [f].

53. Biennial. Flowering from june to auguſt.

This and the foregoing ſort were found by Maſſon at the Cape of Good Hope, and were introduced in 1774 [g].

54. This is allied to C. glomerata (n. 16.) and ſhould come next in order to that. It differs in having ſhorter reflex leaves, peduncles turbinate ſeeming to be an inferior germ, calyxes obtuſe, corollas rather longer than the calyx. Annual. Flowering in july. Found at the Cape by Maſſon, and introduced 1788 [h].

55. Shrubby. Flowering in june. Introduced about 1760, by Mr. Clark [i].]

56. Stem near three feet high, erect, dividing into many branches. Leaves of a lively green, half-ſtem-claſping.

[Shrubby. Flowering in april and may. Cultivated by Mr. Miller in 1759.

57. Biennial. Stem ſcarcely a ſpan in height. Leaves fleſhy, ſmooth, with minute red impreſſed dots ſcattered over them, and an inch in length. Raceme terminating. Peduncles diſtant, ſpreading, ſubdivided into trichotomous cymes. Leaflets of the calyx ſmooth, a line in length. Petals twice the length of the calyx, white with greeniſh bottoms. Nectaries yellow. Filaments white. Anthers roundiſh, ſmall.—It flowers from june to auguſt: was brought from the Cape by Maſſon: and was introduced in 1774 [k].

58. Biennial. Flowering in july.

59. Annual. Flowering in july.

60. Shrubby. Flowering in july and auguſt.

61. Shrubby. Flowering in july and auguſt.

62. Shrubby. Flowering in ſeptember and october.—All theſe were found at the Cape by Maſſon; and were introduced 1774 [l].

[z] Thunberg. [a] Ibid. [b] Ibid. [c] Ibid. [d] Ibid. [e] Ibid. [f] Hort. kew. [g] Ibid. [h] Ibid. [i] Ibid. [k] Ibid. [l] Ibid.

63. This is a thick annual plant, ſcarcely three lines in height. Stem red. Leaves ſeſſile, green with a red dot at the end, becoming red by age. Calyx four or five-cleft. Petals four or five, whitiſh with a red keel, having a little bracte at the baſe of each. Stamens four or five. Germs and capſules four or five. It is almoſt always deficient in one-fifth part of the fructification; and differs from C. rubens in having globoſe-ovate leaves, imbricate in four rows.—Common near Madrid, flowering in march [m].

64. Root perennial. The whole of this plant is ſmooth. Stem one or two, annual, round, fleſhy, the ſize of a quill, a ſpan high, upright, ſubpellucid, almoſt upright, pale fleſh-colour, ſhining, undivided. Root-leaves none. Stem-leaves two, ſometimes only one, convex, repand, brittle, above green with pale rays, appearing dotted when viewed with a magnifier, beneath red-purple, the largeſt three inches in diameter. Racemes to each leaf two, oppoſite, erect, ſlender, from an inch to two inches in length. Lower peduncles oppoſite, one-flowered or umbelled. Flowers ſmall, without ſcent. Calyx dotted, green. Petals twice as long as the calyx, white within, fleſh-coloured without. Nectareous ſcales before the petals brown. Moſt of the flowers have ſix ſtamens and ſtyles, with the calyx and corolla ſix-parted.—Native of the Cape of Good Hope [n].]

PROPAGATION AND CULTURE.

1. This, and all the hardy ſorts are propagated by cuttings during any of the ſummer months; they ſhould be cut off about a fortnight before they are planted, and laid in a dry place that the wounded part may heal over; then they ſhould be each planted in a ſmall pot filled with light ſandy earth, and plunged into a moderate hot-bed, giving them but little water. In about ſix weeks theſe will have put out roots and begin to grow, when they ſhould have a large ſhare of air admitted to them, and muſt be gradually inured to bear the open air, into which they ſhould be removed, placing them in a ſheltered ſituation, where they may remain till autumn; when they muſt be removed into a dry airy glaſs-caſe, where they may enjoy the ſun as much as poſſible, and be ſcreened from the wet and cold. In warm dry weather, during the ſummer months while they are abroad, theſe plants ſhould be gently watered two or three times a week; but in winter they ſhould have very little water, leſt it rot their ſtems. Theſe plants require no artificial heat in winter, but they muſt be ſecured from froſt and wet.

11. Being pretty hardy, ſhould not be ſo tenderly treated; for if the cuttings are planted in a border of light earth, they will put out roots, and may afterwards be taken up and potted, to be ſheltered in winter.

[23, 24. Are hardy plants. The firſt of theſe may be increaſed in the ſame manner with the Sedums; the other being annual muſt be propagated by ſeeds.

25, 26. Theſe are propagated by the heads or offſets, laid to dry three or four days before they are planted, during any of the ſummer months. They are hardy, and may be treated as n. 11.

27. Is eaſily increaſed by its trailing branches, and is hardy, but unleſs the plants are often renewed they will decay.

All the hardy ſorts of Craſſula may be treated in the ſame way as the Ficoides, or Meſembryanthemums, and other hardier kinds of ſucculent plants, with this difference only, not to give them ſo much water; but the firſt, ſixth, and ſome other ſorts require to be placed in a warm dry glaſs-caſe in winter, and muſt not be ſo long expoſed abroad in the ſummer as the other ſpecies, nor ſhould have much water, eſpecially in the winter.

15. Cratægus glabra.
Lin. syst. 465. *Thunb. jap.* 205.
Leaves oblong acute smooth serrate, flowers in a compound panicle.]

16. Cratægus cordata. *Maple-leaved Hawthorn.*
Ait. hort. kew. 2. 168.
Mespilus cordata. *Mill. dict. n.* 4. *fig. t.* 179.
M. Phoenopyrum. *Lin. suppl.* 254.
Thorny; leaves cordate-ovate gash-angled smooth, petioles and calyxes without glands, flowers five-styled.

17. Cratægus pyrifolia. *Pear-leaved Hawthorn.*
Ait. hort. kew. 2. 168.
C. Leucophleos. *Moench. hort. weissenst.* 31. *t.* 2.
Thorny or unarmed; leaves ovate-elliptic gash-serrate, somewhat plaited and hirt, calyxes a little villose, leaflets linear-lanceolate serrate, flowers three-styled.

18. Cratægus elliptica. *Oval-leaved Hawthorn.*
Ait. hort. kew. 2. 168.
Thorny; leaves elliptic unequally serrate smooth, petioles and calyxes glandular, berries globular five-seeded.

19. Cratægus glandulosa. *Hollow-leaved Hawthorn.*
Ait. hort. kew. 2. 168.
Thorny; leaves obovate-wedgeform angular smooth glittering; petioles stipules and calyxes glandular; berries oval five-seeded.

10. Cratægus flava. *Yellow pear-berried Hawthorn.*
Ait. hort. kew. 2. 169. *Moench. hort. weissenst.* 62. *t.* 4.
Thorny; leaves obovate-wedgeform angular smooth glittering; petioles stipules and calyxes glandular; berries turbinate four-seeded.

11. Cratægus parvifolia. *Gooseberry-leaved Hawthorn.*
Ait. hort. kew. 2. 169.
C. uniflora. *Du Roi bort. harbecc.* 1. 184.
Mespilus. *Mill. dict. edit.* 7. *n.* 17.
Thorny; leaves wedgeform-ovate gashed serrate; calycine leaflets gashed, the length of the fruit, flowers five-styled.

22. Cratægus sanguinea.
Pallas fl. ross. 1. 25. *t.* 11.
Thorny; leaves seven-angled serrate, produced at the base, petioles submarginate.

23. Cratægus Bibas.
Lour. cochinch. 319. *Pluk. amalth.* 26. *t.* 371. *f.* 2. (Pi-pa.)
Unarmed; leaves lanceolate serrate tomentose; racemes terminating bifid.

DESCRIPTIONS, *&c.*

This genus consists chiefly of Shrubs or Trees, hardy and deciduous. Leaves simple, undivided or lobed. Peduncles in most species many-flowered corymbed terminating, and solitary from the axils; in a few one-flowered axillary, and in terminating spikes[a]. Corollas white, appearing in may and june, succeeded by bunches of red berries in autumn.]

1. This tree rises to the height of thirty or forty feet, with a large trunk, dividing into many branches; the young shoots have a brown bark, covered with a mealy down; the leaves are between two and three inches long, and one inch and a half broad in the middle, of a light green on their upper side, but very white on their under, having many prominent transverse veins, running from the midrib to the border, where they are unequally serrate, some of the teeth being much deeper, and the segments broader than others. The flowers are produced at the ends of the branches in bunches for corymbs, two inches or more in diameter, and very much branched. The peduncles are tomentose, and have a lanceolate caducous bractæ. Calyx tomentose, divided into five, sometimes six, reflex segments. Petals five, sometimes six, frequently scalloped at the end, woolly at the base, white. Filaments sometimes as many as twenty-one. Styles two or three (two to four, with as many seeds, *Du Roi*. four or five. *Duham.*) woolly at the base. Berries somewhat tomentose, red, containing from two to four seeds[b]: four, in each cell two, according to *Crantz*.—or, as Scopoli says, two cells with one seed in each, or one with two seeds.]

Native of most parts of Europe: chiefly on dry hills and open exposures, in gravel, clay or chalk, and from the fissures of lime-stone rock.—With us in the northern, western, and southern parts of the island; in Derbyshire, Norwood near London, and formerly on Hamstead heath, &c. Flowering in may.

Mr. Miller says it is called *White Leaf tree*. According to Mr. Ray, in Worcestershire and Staffordshire, in Lancashire and Westmoreland it has the names of *Red Chefs-Apples* and *Sea Owlers*. In Derbyshire, they call it the *Wild Pear-tree*. Gerarde calls it *Cumberland Hawthorn*. In German it is named *Mehlbeerbaum* or *Mehlbaum*; in Danish, *Axelbær*; in Swedish, *Oxel*, *Oxeltræd* or *Oxelbær*; in French, *Alizier*; in Italian, *Aria* or *Sorbo pelofo*; in Spanish, *Moßaco*.

The wood, being hard, tough and smooth, is used for axle-trees, wheels, walking-sticks, and the handles of tools. The fruit is eatable when mellowed by the autumnal frosts, and an ardent spirit may be distilled from it[c].

The straight handsome growth of the tree, the smoothness of the bark, the extreme whiteness on the under surface of the leaves, the handsome bunches of white flowers on their mealy peduncles, succeeded by red berries, render this a desirable tree to mix with others in ornamental plantations. It bears lopping, and permits grass to grow under it.

β. The Swedish variety has the leaves deeply sinuated, pinnatifid, and even pinnate. The British tree never is so. Haller remarks that the fruit of this is bitter.—It also varies with leaves not tomentose or white underneath; in the variety the peduncles, fruit, &c. are destitute of nap.]

2. This rises to the height of forty or fifty feet, with a large trunk, spreading at the top into many branches, so as to form a large head. The young branches are covered with a purplish bark, marked with white spots. Leaves alternate, on pretty long foot-stalks, cut into many acute angles, like those of the Maple-tree; they are near four inches long, and three broad in the middle, having several smaller indentures towards the top; they are of a bright green on their upper side, but a little woolly on their under. The flowers are produced in large bunches towards the end of the branches; they are white, and shaped like those of the Pear-tree, but smaller, and on longer peduncles: they appear in may, and are succeeded by roundish compressed fruit, shaped like common Haws, but larger; ripening in autumn, when they are of a brown colour, and if kept till they are soft, in the same way as Medlars, have an agreeable acid flavour.

[Styles, according to Haller, two or three, so glued together as to seem but one. Seeds two to four; as Crantz says, in two cells.]

The wood of this tree is hard and very white; it is useful for many purposes, particularly in mill-work. The fruit is sold in the London markets in autumn.

[a] Jussieu.

[b] Pollich.

[c] Withering.

[Native of Denmark, Germany, Auſtria, Switzerland, Burgundy, Piedmont,] England, in many parts, chiefly upon ſtrong ſoils. In Caen-wood and Biſhop's-wood near Hamſtead, in Hertfordſhire, &c.

β. The alpine variety, which Miller makes a diſtinct ſpecies, is about twenty feet high. Leaves oblong-ovate, ſlightly ferrate, on very ſhort footſtalks, about three inches long, and one inch and a half broad, leſſening towards both ends, deep green on both ſides. Flowers in ſmall bunches, rarely more than four or five flowers in each. Fruit the ſize of the common Haw, but dark brown. Native of monte Baldo, and other mountains of Italy.

3. This riſes to the height of near twenty feet in England, with a large upright trunk, dividing into many ſtrong, irregular, ſmooth branches, ſo as to form a large head. Leaves large [and bending backwards;] they are about four inches long, and three and a half broad, have five or ſix pairs of ſtrong nerves, and become of a browniſh red in autumn.] The flowers come out from the ſide of the branches in large cluſters; they are large, make a noble ſhow in may, and are ſucceeded by large pear-ſhaped fruit of a bright ſcarlet colour, which ripens in ſeptember.

[Branches marked with irregularly ſcattered dots. Thorns axillary, ſtout, ſpreading very much, from the rudiments of the branches. Peduncles pubeſcent, corymbed. Native of Virginia and Canada[a]. Cultivated 1696, by Mr. Jacob Bobart[c].

4. This is probably a variety of the foregoing. Theſe North American ſpecies vary much in having thorns or none, in the number of the ſtyles, and form of the leaves.

5. Branches diffuſe, no thorns, leaves obovate, acute, unequally double-ſawed, very ſmooth on both ſides. Stipules linear, ciliate-ſawed, caduous. Racemes compound, moſt of the partial ones trifid. Styles two or three. Fruit orange-red, dotted with brown, whitiſh within; ſtones very hard, the ſame number with the ſtyles. Native of America[f].

Cultivated 1746, by Archibald Duke of Argyle[g].

6. Stem ſtrong, ten or twelve feet high; bark of the ſtem rough, of the branches ſmooth and reddiſh. Leaves lanceolate, three inches long, and one inch broad in the middle, ſerrate, of a lucid green, alternate; at many of the joints are ſmaller leaves in cluſters: thorns axillary, very ſtrong, two inches in length. Flowers axillary, in roundiſh cluſters, generally two together; petals white, with a bluſh of red. Stamens ten; anthers bright red. Styles three. Fruit globular, of a fine red colour. It flowers in june[b].

Native of North America. Mr. Miller ſays, that the fruit was ſent to him from Philadelphia.

Cultivated 1691, by the hon. Charles Howard[f].]

7. This has a ſlender ſhrubby ſtem, about ſix or ſeven feet high, ſending out many irregular branches, armed with long ſlender thorns. The flowers are ſmall, proceeding from the ſide of the branches, ſometimes ſingle, and at other times two or three upon the ſame peduncle, having large leafy calyxes, and being ſucceeded by ſmall roundiſh fruit. The flowers appear at the beginning of june, and the fruit ripens very late in the autumn.

Native of North America.

[There is a variety of this, called in the nurſeries Carolina Hawthorn, which has longer and whiter leaves, larger flowers and fruit, but no thorns[k].

8. A large tree, without thorns. Leaves broad-lanceolate, obtuſely ſerrate, thickiſh, petioled. Corymbs terminating, with ſcaly peduncles and ſubulate bractes[l]. Styles two. Berries roundiſh, containing from two to four ſeeds[m]. Native of the Eaſt Indies, and Cochinchina.

The wood is reddiſh, heavy and tough; it is fit for oars and other uſes that require toughneſs[n].

[a] Linn. mant. [b] Hort. kew. [c] Jacquin,
[d] Hort. kew. [e] Mill. fig. [f] Hort. kew. from Pluk.
[g] Hunter's Evelyn, [h] Linn. ſpec. [i] Loureiro.
[k] Ibid.

β. Styles two, ſometimes three or four. Seeds uſually two, but ſometimes one, three, or four[e].

10. There is ſuch uncertainty in the number of ſtyles in this genus, that we can hardly conſider the *monogyna* of Jacquin as a diſtinct ſpecies. Our Britiſh ſhrub is ſuppoſed to be this, and not the *C. Oxyacantha* of Linnæus and others. Yet Mr. Lyons has obſerved that the ſtyle at firſt ſimple, is afterwards divided into two; and Dr. Withering obſerved two ſtyles in one plant.

Mr. Lyons thus deſcribes our ſhrub.—Trunk aſcending, round, very much branched. Bark ſmooth. (At the baſe of each petiole two ſemiorbicular ſtipules, deeply toothed, acuminate at top.) Thorns ſharp, (coming out from between the ſtipules.) Leaves trifid, petioled, decurrent, ſharp at the baſe, ſhining, the middle ſegment trifid, very entire about the edge, (commonly in the upper floral leaves, but ſerrate in the branch leaves.) Peduncles branched, with two or three flowers on each diviſion. Calyx hirſute, having five reflex, acute ſegments. Petals wrinkled on the edge. (Stamens ſixteen.) Anthers red[p].

Scopoli ſays that he has examined thouſands of fertile flowers, and that he conſtantly obſerved one ſtyle, and one ſtone. Villars affirms that he has rarely ſeen two ſtyles. Scopoli remarked ſome barren flowers to be digynous or ſemidigynous. D'Alſo ſays that the Hawthorn is conſtantly monogynous in Spain.

According to Allioni, C. monogyna has the leaves more ſhining, extremely ſmooth, deeply cut into three or five lobes; the peduncles ſmooth, the ſegments of the calyx reflex; and one ſeed only conſtantly in the fruit.

The common Hawthorn and its varieties flower uſually in may. In 1783 the Hawthorn began to flower on the 21ſt of march; the year following it was ſix weeks later. It was almoſt as early in 1794, and as late in 1795. The extremes of flowering in Mr. White's calendar are from april 20th to june 11th. Some flowers yet remain on the buſhes the 20th of june 1795, the day on which I have written the above.

The Glaſtenbury variety flowers uſually in january or february, ſometimes earlier, ſo that it may happen to be in flower on Chriſtmas day. Dr. Stokes ſuſpects this to be C. Oxyacantha of Linneus.

Few trees exceed the Hawthorn in beauty during the ſeaſon when it is in bloom. It is proper therefore for ornamental plantations, and particularly to ſtand ſingle in lawns or parks, where it will grow to the height of twenty or even thirty feet; the trunk ſometimes meaſuring from five to nine feet in circumference[q]. The wood is tough, and may be uſed for axle-trees and the handles of tools. The root of an old thorn, ſays Evelyn, is excellent both for boxes and combs: when planted ſingle, it riſes with a ſtem big enough for the uſe of the turner, and the wood is ſcarcely inferior to box. A decoction of the bark yields a yellow dye; and with copperas is uſed to dye black. The berries are the winter food of the Thruſh and many other birds; ſwine alſo and deer are fond of them. The peaſants in many countries eat them, and in Kamſchatka they alſo make a wine of them[r].

It is well known that the White-thorn makes the beſt quick or live fences. See HEDGES.

In German it is named *Hagedorn*; in Daniſh, *Hagetorn*; in Swediſh, *Hagtorn*: whence our *Hawthorn*; the fruit being called *Haws*. It is called alſo in Engliſh, *White-thorn*; and of ſome Londoners, ſays Gerarde, *May-buſh*: when uſed for hedges, *Quick*. In French, *Aubepine*, or *Epine blanche*; in Italian, *Biancoſpino*; in Spaniſh, *Eſpino blanco*.

Of the Varieties:

β. The fruit of the ſecond is exceedingly large, oblong, ſmooth and bright ſcarlet.—ε. The Yellow has the buds at their firſt appearance in the ſpring,

[p] Haller, Jacqu. & Du Roi. [q] Relh. cant.
[r] Boutcher. [s] Lightfoot.

of a fine yellow, and the fruit is of a golden colour. It is a great bearer, and retain its fruit all winter. It was originally brought from Virginia.—ζ. The White is but a paltry tree.—δ. The Double-bloſſomed is one of the greateſt ornaments of our ſhrubberies, and may be kept down to any ſize. The beautiful flowers come out in large bunches in may, and the ſhrub often appears covered with them: they are at firſt of a pure white, and die to a faint red: they are frequently ſucceeded by ſmall imperfect fruit[s].

Pallas has deſcribed and figured another variety under the name of *C. monogyna nigra*, the berries of which finally turn black.]

11. This has a ſtrong ſtem twenty feet high, having many ſtrong irregular branches, covered with a light-coloured bark; the leaves are in ſhape ſomewhat like thoſe of the common Hawthorn, but they are much larger, have broader lobes, and are of a paler colour; the flowers come out in ſmall cluſters from the ſide of the branches, and are in ſhape like thoſe of the common Hawthorn, but much larger; as is alſo the fruit, which when fully ripe has an agreeable acid taſte, for which it is eſteemed in Italy and the Levant, where it is ſerved up in the deſert.

[It ſeems to differ from common Hawthorn (n. 9.) only in the ſize, as *Sorbus domeſtica* from *ſylveſtris*; in this all the parts are four times the ſize of the other; there are few thorns, or even none in the cultivated plant[t]. The fruit has five cells as in the pear[u].

Native of the ſouth of Europe, the Levant, &c. Cultivated 1656, by Mr. John Tradeſcant[x].

12. Stature and appearance of *C. Oxyacantha*. Bark aſh-coloured. No ſpines. Leaves oblong or ſublanceolate, obtuſe, gloſſy, three or five-toothed at the end; the teeth acute. Flowers in branched corymbs, reſembling thoſe of common Hawthorn. Native of Barbary[y].

13. Leaves alternate, petioled, ovate-oblong, veined, villoſe, two inches long. Petioles round, ſmooth, ſcarcely half an inch in length. Flowers terminating, in a compound umbel. Peduncles about ſix, pedicels three or four, all filiform, tubercled, villoſe, an inch in length. Styles two. Fruit villoſe[z].

14. Stem ſmooth. Branches and branchlets alternate, aſh-coloured, ſpreading. Leaves from alternate buds three or four, petioled, very finely ſerrate, plane, thin, ſpreading very much, unequal, an inch in length. Flowers terminating, ſpreading very much. Umbel generally ſimple, but ſometimes with one trifid or racemed ray. Peduncles capillary, callous, an inch long. Perianth only half the length of the corolla. Petals ovate, entire, white, a line long. Stamens ſhorter than the corolla. Styles two.—It differs from the foregoing, in having leaves broader in the middle, drawn more to a point at both ends, aggregate, not ſolitary; and in the umbel being almoſt ſimple[a].

15. Branches and branchlets ſubverticillled, ſtriated, ſmooth, ſpreading. Leaves ſcattered, petioled, a little reflected on the edge, perennial, veined, paler underneath, ſpreading very much, of a finger's length. Petioles angular, grooved, ſmooth, ſpreading. Flowers terminating, in a ſubfaſtigiate panicle. Peduncles angular, ſmooth; the pedicels gradually ſhorter, and more approximating. Perianth five-toothed, ſmooth, half the length of the corolla. Petals obovate, obtuſe, entire, white, villoſe at the baſe, ſpreading. Filaments the length of the corolla; anthers globular, twin. Styles two.—It differs from the two foregoing in having oblong, not ovate leaves, thicker and evergreen; petals villoſe at the baſe; and a large compound panicle[b].—Theſe three were found in Japan, by Chevalier Thunberg. This is a tree, and the two former ſhrubs.

16. Riſes with a ſtrong woody ſtem about four feet high, ſending out many ſpreading branches, which incline to a horizontal poſition. Leaves different in form, ſome indented at the petiole, others not; they are about an inch and half long, and nearly of the ſame breadth in the middle, ending in acute points, and their borders cut into ſeveral acute parts, which are ſharply ſerrate; they are of a bright green, and ſtand on very ſlender petioles, about an inch in length. The branches are armed with a few pretty long ſlender ſpines. The flowers come out in ſmall bunches from the ſide of the branches. Stamens eight. Styles four. Fruit round, containing two ſeeds[c].

Branches ſpotted with white. Leaves cut into three, five or ſeven ſegments, acuminate, the ſize of Birch-leaves. Petiole very ſlender, ſhorter than the leaves. Corymb compound. Bractes at the baſe of the peduncles, ſolitary, ſubulate, very ſmall, deciduous. Flower ſomewhat ſmaller than the common Whitethorn. Teeth of the calyx very ſhort, obtuſe, falling off when the fruit is ripe. Styles five. Fruit an oblate ſpheroid, ſcarlet, the ſize of a red Currant; the navel looſe, naked. Stones five, the tops filling up the navel, and naked. It flowers the laſt of the genus[d].

This ſort was raiſed in the Chelſea garden in 1738, from ſeeds which came from North America, by the title of *New Haw*.—It flowers the latter end of june, and the fruit ripens in the autumn[e].

17, 18. Natives of North America. Introduced 1765, by Meſſrs. Kennedy and Lee[f].

19. This has very ſtout thorns. It flowers in may and june; is a native of North America; and was cultivated in 1750, by Archibald Duke of Argyle[g].

20. There are often ſmall leaves on the thorns, which in this and the following ſpecies are ſlender, and a little bent in at the end. This flowers in may; is a native of North America; and was cultivated in 1758, by Mr. Miller[h].]

21. This is a ſhrub of humble growth, ſeldom riſing more than ſix or ſeven feet, ſending out a great number of ſlender branches, which are interwoven, and armed with very long ſlender ſharp thorns. The leaves are ſcarcely one inch long, and ſome are not more than half an inch broad, but others are almoſt as broad as they are long; they are ſerrate, and have very ſhort foot-ſtalks. The flowers are produced at the end of the branches, generally one coming out from between the leaves; but ſometimes there are two or three, one below the other at the axils; they have large leafy calyxes, much longer than the petals; they are ſmall, have twelve or more ſtamens, and four ſtyles. The fruit is ſmaller than that of the common Hawthorn, and is of an herbaceous yellow colour, when ripe. The ſeeds were ſent from Virginia by Baniſter, and ſome of the plants were raiſed in Biſhop Compton's garden at Fulham before 1713, and afterwards by Archibald Duke of Argyle at Whitton. It is generally known by the name of Lord Iſlay's Hawthorn, and flowers in may and june.

[22. Height frequently from two to three fathoms. Trunk the thickneſs of the human arm or thigh, very much branched from the bottom, and ſpreading. Branches ſometimes unarmed, but ſometimes armed with long and very ſpreading thorns, covered with a bark of a reddiſh teſtaceous colour, with aſh-coloured ſpots here and there. The bark of the trunk is of a brown teſtaceous colour, thin, and peeling off in aſh-coloured ſcales. Leaves alternate, ſuborbiculate, more or leſs acute, and produced at the baſe, running down unequally into the petiole, three times gaſhed at the edge on each ſide, and unequally ſerrate; the veins underneath ſubferruginous, and the whole lower ſurface pubeſcent. Petioles ſhort, pubeſcent. Stipules lanceolate, ſerrate, ſhrivelling. Flowers in corymbs at the ends of all the branchlets; theſe are ſo abundant, that

[s] Hunter. [t] Linn. ſpec. [u] Scopoli.
[x] Hort. kew. [y] Linn. ſuppl. [z] Thunberg.
[a] Ibid. [b] Ibid. [c] Mill. fig. [d] Linn. ſuppl. [e] Mill. fig.
[f] Hort. kew. [g] Ibid. [h] Ibid.

the tree is very handſome when in flower and fruit. Peduncles ſmooth, with ſlender, linear bractes, that fall off at flowering time. Corollas rather large, nearly the ſame ſize as in *C. coccinea*. Styles two or three, very frequently four. Stamens about ſeventeen; anthers purple, twin. Fruit large, very red, ſubglobular, two-celled, two or four-ſeeded. It flowers at the end of may; the fruit ripens at the end of auguſt, and after the firſt froſts in ſeptember becomes very eatable. The leaves acquire a ferruginous tinge at the beginning of winter.

This has broader leaves than *C. Oxyacantha*, and of a different form, the ſtipules lanceolate, and all the parts of fructification large. It differs from *C. coccinea* in having the leaves pubeſcent, produced at the baſe, on ſhorter petioles without any glands, and ſmaller flowers.

Native of Siberia; and perhaps the Cratægus of Kamtſchatka[i].

23. This is a middle-ſized tree, with ſpreading branches. Leaves unequally ſerrate, ſcattered, on ſhort petioles. Flowers white, in large bunches. Styles two. Fruit middle-ſized, pear-ſhaped, yellow, lanuginoſe, of a ſweet acid flavour, juicy, eatable; the ſkin thin, the pulp white; one-celled, containing two or three ſeeds.—Cultivated abundantly about Macao and Canton in China[k].]

PROPAGATION AND CULTURE.

1. The White Beam tree may be propagated by ſeeds, which ſhould be ſown ſoon after they are ripe; for if they are kept out of the ground till ſpring, they remain at leaſt one year in the ground before the plants appear; ſo that the fruit ſhould be buried in the ground, as is practiſed with the common Haws, Holly-berries, and thoſe other hard ſeeds which do not come up the ſame year; and when the plants come up, they may be treated in the ſame manner as the Haws, but they ſhould by no means be headed or cut down. On a poor chalky ſoil they make great progreſs, and the wood is very white and hard.

It may alſo be propagated by layers in the ſame manner as the Lime and Elm, but theſe ſhould be laid in the young wood: two years elapſe before they have ſufficient roots to tranſplant. It may alſo be raiſed from cuttings planted in autumn in a ſhady border, but not an eighth part will ſucceed. Trees raiſed from ſeeds grow much larger and ſtraighter, than from layers or cuttings.

This tree will take by grafting or budding upon Pear-ſtocks very well, and Pears will take by grafting upon this. Although both theſe will ſometimes take upon the Meſpilus, yet neither of them thrive ſo well, or laſt ſo long, as when they are grafted or budded upon each other.

2. The Wild or Maple-leaved Service may be propagated in the ſame way, but requires a ſtrong ſoil.

3 to 7. and 16 to 21. All the ſorts of American Hawthorn may be raiſed from ſeeds ſown in autumn, in the ſame manner as the firſt ſort, or as the common Hawthorn: but as theſe ſeeds being brought from America, frequently do not arrive here till ſpring, the fruit may be buried in the ground till the autumn following, when they may be taken up and ſown in drills, being careful to cover them ſo as to prevent birds from deſtroying them. In the ſpring following the plants will come up, which ſhould be moderately watered two or three times a week, if the ſpring ſhould prove dry; during the ſummer, they muſt be kept clean from weeds, which if ſuffered to grow, will ſoon overbear the plants and deſtroy them. The following ſpring the plants ſhould be planted out before they begin to ſhoot, into a nurſery-bed, where they may grow two years to get ſtrength, when they may be tranſplanted where they are to remain. If theſe are planted in a moiſt light ſoil, their roots will extend to a conſiderable diſtance, and put up many ſhoots, which may be taken off in the ſpring, and thereby may be increaſed; theſe will alſo take if grafted on the Pear, and if the young branches are laid down, they will take root.

The ſeveral ſorts of Hawthorn are generally planted among flowering ſhrubs of the ſame growth, where they add to the variety.

The varieties of the Hawthorn are continued by budding upon ſtocks of the common ſort. The ſame method alſo is commonly practiſed for ſeveral of the ſpecies. See INOCULATING.—The largeſt and moſt beautiful plants however are raiſed from ſeed.

[*White-thorn, Haw-thorn*, or *Quick*.

9, 10. The moſt uſual practice, in raiſing the White-thorn, is to ſow the berries, either in october or november, or elſe very early in the ſpring, either broadcaſt or in drills, in beds about four feet wide, with alleys eighteen inches wide between each; covering the berries an inch deep, with freſh light mould. Thus, though moſt of them ſhould not come up till the ſecond ſpring, yet they will have the continual benefit of the ſun, air, and rain; all which, it may be preſumed, will make them come up better and ſhoot ſtronger, than when they are buried in a heap during more than a year.

The latter method however is preferred by many: I have therefore ſubjoined Mr. Boutcher's practice, eſpecially as it contains ſome uſeful directions on this ſubject.

The Haws ſhould remain on the buſhes till the end of october, when they become blackiſh. If you do not ſow them immediately, as ſoon as they are gathered, ſpread them on an airy floor for five or ſix weeks, till the ſeeds are dry and firm; then plunge them into water, and diveſt them wholly of their pulp, by rubbing them between your hands with a little ſand: ſpread them again on the loft three or four days, till quite dry, mix them with fine looſe ſandy mould, in quantity not leſs than the bulk of the ſeeds, and lay them in a heap againſt a ſouth wall, covering them over three or four inches deep with ſoil of the ſame quality as that with which they are mixed. If you do not ſow them in the ſpring, in this ſituation let them remain till the ſecond ſpring, as the ſeeds, if ſown, will not appear the firſt year.

That the berries may be as equally mixed with the ſoil as poſſible, turn over the heaps once in two months, blending the covering with the ſeeds; and at every turning, give them a freſh covering in the winter months.

They muſt be ſowed the firſt dry weather in february, or the beginning of march. Separate them from the looſe ſoil in which they were mixed, with a wire ſieve. The ground ſhould be good dry freſh land, well prepared. Divide it into beds three feet and a half broad, with alleys of eighteen inches. Puſh over a little of the ſurface of the beds into the alleys; ſow them with great care, ſo that they may not riſe in cluſters, and that the plants may in general be at leaſt an inch aſunder. Clap them into the earth with the back of a ſpade, draw the ſoil back from the alleys, and let not the ſeeds be covered more than half an inch deep. The ſucceeding ſpring, draw out all the largeſt plants where too thick; ſhorten their roots; lay them in lines a foot aſunder, and four inches diſtant in the rows, having cut off ſo much of their tops as to leave them about two inches above ground; and let them remain two years.

Thoſe who are not ſtraitened for ground, may drop the ſeeds in drills eight inches aſunder, and double that diſtance between each pair of drills. The following ſpring they may be drawn where too thick, and the remainder cut with a ſpade, five or ſix inches below ground; to remain another year.

Thorns alſo may be propagated to much advantage, and two years time ſaved, by cuttings from their roots. For this purpoſe, at removing a nurſery of theſe plants, cut off all unneceſſary roots that are ſtraight and clean, of one or not more than two

[i] Pallas. [k] Loureiro.

years growth; let them not exceed the length of four or five inches; and either early in october or february, lay them in drills cut out with the ſpade, with their tops a quarter of an inch below the ſurface: let theſe drills be a foot aſunder, and lay the roots three or four inches ſeparate. The following ſpring they ſhould be cut within three or four inches of the ſurface. In general they will be eighteen inches high, and well rooted, at two years old.

Which ever way the Thorns are propagated, in october they ſhould be planted out in rows, at leaſt eight inches aſunder, and ſix inches in the row, their roots having been ſhortened, and their tops cut of, ſo as to ſtand four or five inches above ground. In this nurſery they ſhould remain no more than two years: the ground being dug ſpring and autumn, and the plants cut the firſt ſeaſon an inch or two above the former cutting.

When removed again, they ſhould be in rows four feet aſunder, and two feet diſtant in the row: they ſhould alſo be cut to the height of a foot or fourteen inches; and about the end of june, clipped ſtraight in the ſides and thin in the tops. Having ſtood a year longer, cut them again to the height of two feet or thirty inches, and clip them as before. The third ſeaſon they may be cut at three feet and a half high about midſummer, and the following autumn they may be planted for handſome hedges four feet high.

If plants of a larger ſize are deſired, as ſix feet high, they muſt be removed once more, and remain three years.

Quick thus removed, and planted out large, will make an almoſt immediate fence, and ſave much charge in countries where fencing is very expenſive.

For the management of White-thorn, or Quick hedges, ſee the two articles HEDGES and QUICK.

Leaflets and petals obovate, germ oblong.

DESCRIPTIONS, *&c.*

Theſe are trees with ternate leaves, and the flowers in terminating panicles[a].

1. Trunk twelve feet and more in height, and unarmed. Branches ſpreading, round, unequal, rugged, dotted; the younger ones herbaceous, green, very ſmooth. Leaves alternate, eſpecially towards the ends of the branchlets. Petioles longer than the leaves, round, ſmooth, green. Leaflets petioled, acute, nerved, veined, very ſmooth, thin, deep green. Raceme terminating, erect, ſtrict, many-flowered. Flowers rather large, purple, on round ſmooth peduncles from one to two inches in length, and without bractes. Calyx goblet-ſhaped, four-cornered, with a rounded fleſhy unequal border. Leaflets four, inſerted into the margin, oppoſite, ovate, acute, patulous, deciduous. Petals two, very ſeldom four, placed on the ſides of the upper calycine leaflet, aſcending, erect, ovate-lanceolate, entire, whitiſh. Filaments twenty to twenty-four, inſerted into a columnar receptacle, patulous, longer than the petals, declining, filiform, green, tinged with purple. Anthers erect, linear, a little curved, two-valved, very dark purple: but the pollen yellow. Germ pedicelled, roundiſh, ſmall: ſtyle none: ſtigma ſeſſile, ſubcapitate, brown. Pericarp ovate, berried, two-celled, many-ſeeded.

The pedicel of the germ is at firſt very ſhort, but finally becomes as long as the ſtamens. In ſome flowers the piſtil is wholly wanting, the plant therefore is polygamous. It has a burning taſte, and a nauſeous ſmell. It approaches ſo near to *Cleome*, as hardly to be diſtinguiſhed from it, except by the fruit[b]. Linneus remarks, that it differs from *C. Tapia* in having thin leaves, the petals ovate, not lanceolate, but eſpecially in having the ſtamens elevated on a column the height of the calyx, as in *Cleome gynandra*.

Native of Jamaica, in dry coppices near the ſea; flowering in may and june.]

2. This tree has a very large trunk, which riſes to the height of thirty feet or more, covered with a dark green bark, ſending out many branches, ſo as to form a large head. The branches are garniſhed with trifoliate leaves, ſtanding on pretty long footſtalks; the middle leaf, which is much larger than either of the other, is oval, about five inches long, and two and a half broad in the middle. The two ſide leaves are oblique, thoſe ſides which join the middle leaf being much narrower than the other, and turn at both ends toward the middle, ſo that their midrib is not parallel to the ſides; theſe two end in acute points. They are all ſmooth, of a light green on the upper ſide, but pale on their under: their edges are entire. The flowers are produced at the ends of the branches, ſtanding upon long peduncles, The fruit is about the ſize of an Orange, having a hard brown ſhell, or cover, incloſing a mealy pulp, filled with kidney-ſhaped ſeeds. It has a ſtrong ſmell of Garlic, which is communicated to the animals that feed on it.

[a] Juſſieu. [b] Swartz.

[Vahl adds, that the branches are round, with an ash-coloured bark. The leaves heaped at the ends of the branches, alternate: leaflets petioled, nearly equal, nerved. Pedúncles several, one-flowered. Segments of the calyx short, ovate. Claw of the petals as long as the lamina. Filaments twice as long as the petals.

Linneus remarks, that the flower in this species, as well as the first, has a stipitate germ, like *Cleome gynandra*.

Native of the West Indies. Mr. Miller says,] I received the fruit of this from Jamaica, where it grows in great plenty, which were sent me by William Williams, Esq: of St. Anne's, in that island, who has been so kind as to furnish me with many other curious seeds which[c] have succeeded in the Chelsea garden.

3. This sort is a native of India, where it grows to a great height, with a large trunk, sending out many long branches, garnished with trifoliate leaves; the leaflets are oblong, entire; and end in acute points; between these the branches are armed with long sharp thorns, which come out by pairs, and spread asunder. The flowers are produced in small clusters from the side of the branches, five or seven standing upon a common branching peduncle; these have each five acute petals, which are reflex; they are green on the outside, whitish within, and have a grateful odour. After the flower is past, the germen swells to a large fruit the size of an Orange, having a hard shell, which incloses a fleshy viscous pulp, of a yellowish colour, having many oblong plane seeds situated within it; the pulp of this fruit has an agreeable flavour when ripe, and is frequently eaten in India, where they serve up the fruit, mixed with Sugar and Orange, in their deserts, and it is esteemed a great delicacy.

[Linneus suspects that this may be of a different genus. He observes that the calyx is five-cleft, that the flower has no petals, and sixty stamens.

This and the preceding sort were cultivated by Miller before 1759.

4. Trunk of a middling height, upright. Branches spreading, round, ascending, covered with an olive bark dotted with white. Leaves scattered at the ends of the branchlets: leaflets acuminate, quite entire, smooth, tender, netted with many nerves and veins, a span long, the side ones a little smaller, the anterior edge narrower but not shorter, spreading horizontally. Common petioles spreading, semicylindric, smooth and even, a hand in length: partial petioles very short. Cyme terminating, subcorymbed; and sometimes solitary flowers from the axils of the upper leaves. Peduncles one-flowered, round, smooth, loose, three or four inches in length, spreading, thickish at the base. Flowers an inch and half in diameter, greenish white, with red stamens. Filaments the length of the petals or a little longer. Germ oblong.

Native of the East Indies, and the Society Isles. In the latter it is planted at their burial places, and is supposed to be sacred to their idols. In Otaheite it is called *Pura-au* or *Puratauru*. The fruit is eaten[d].

5. Leaves and leaflets petioled: the latter an inch and half long, the side ones a little smaller, mucronate, smooth, veined underneath. Peduncle heaped at the top, two inches long, one-flowered, segments of the calyx oblong, mucronate. Petals attenuated at the base. Filaments seven to nine, three times the length of the petals. Style longer than the filaments. It does not seem to be a variety of *C. Tapia*, since it differs in the form of the leaflets and petals, the former being nearly equal at the base, the latter having longer claws; the filaments also being longer, and the germ oblong. In other respects it has the habit of the rest. Native of Madagascar[d].]

PROPAGATION AND CULTURE.

These plants are propagated by seeds, which must be procured from the places where it grows naturally; they must be sown upon a good hot-bed in the spring, and when the plants are fit to remove, they should be each transplanted into a small pot filled with light kitchen-garden earth, and plunged into a hot-bed of tanner's bark, shading them every day from the sun, until they have taken fresh root, after which they may be treated in the same manner as the ANNONA; which see. They should be watered sparingly in winter.

CRATEVA. See *Capparis*.

CREPIS. (*The name of a plant in Pliny; derivation unknown. Κρηπις in Greek is the base or foundation of any thing: also a shoe or sandal.*)

Lin. gen. n. 914. *Reich.* 993. *Schreb.* 1239. *Gærtn. t.* 158. Hieracioides. *Vaill. A.G.* 1721. 47. 52. 53. 17. 18.

Class. 19. Syngenesia Polygamia Æqualis.

Nat. order of *Compositæ Semiflosculosæ.—Cichoraceæ. Juss.* 169.

GENERIC CHARACTER.

CAL. *Common* double.

Exterior very short, spreading, deciduous.

Interior ovate, simple, furrowed, permanent. *Scales* linear, converging.

COR. *Compound* imbricate, uniform. *Corollets* hermaphrodite, very many, equal.

Proper one-petalled; ligulate, linear, truncate, five-toothed.

STAM. *Filaments* five, capillary, very short. *Anther* cylindric, tubular.

PIST. *Germ* somewhat ovate. *Style* filiform, length of the stamens. *Stigmas* two, reflex.

PER. none. *Calyx* roundish.

SEED solitary, oblong, fusiform, sometimes columnar. *Down* hairy, generally stipitate.

REC. naked, with cells or pits.

OBS. *The Down in species* 10, 11, 12, 15, 17, 18, 19, 20, *is sessile.*

It is sometimes feathered. Juss.

11, 12, 17, *are subplumose, or somewhat feathered, according to Hudson.*

This genus differs from Hieracium *in the ventricose toruloſe form of the mature calyx: from* Picris *in the simplicity of the down.* G.

ESSENTIAL CHARACTER.

Cal. calycled with deciduous scales. *Down* hairy, stipitate. *Recept.* naked.

Leaves ſagittate toothletted, ſtem paniculed, flowers pyramidal ſmooth.

16. Crepis neglecta.
Lin. ſyſt. 720. *Reich.* 3. 655. *mant.* 107.
Leaves ſtem-claſping runcinate toothed ſomewhat hairy, ſtem panicled, calyxes with one or two ſpines on each leaflet.

17. Crepis albida. *Pale-flowered Crepis.*
Ait. hort. kew. 3. 127. *Lamarck encycl.* 2. 179. *Jacqu. ic. collect.* 1. 81. *Allion. pedem. n.* 800. *t.* 32. *f.* 3. *Villars dauph.* 3. 139.
Leaves runcinate-toothed ſomewhat hoary, peduncles naked one-flowered, calycine ſcales whitiſh at the edge.

18. Crepis rigens. *Briſtly-leaved Crepis.*
Ait. hort. kew. 3. 127.
Leaves oblong doubly ſerrate briſtly; ſtem naked, branched; flowers panicled; calyxes cylindric ſmooth; down ſeſſile.

19. Crepis filiformis. *Fine-leaved Crepis.*
Ait. hort. kew. 3. 128.
Leaves linear-filiform very entire ſmooth; down ſeſſile.

20. Crepis fucculenta. *Fleſhy-leaved Crepis.*
Ait. hort. kew. 3. 128.
Leaves pinnatifid or toothed ſomewhat fleſhy even; calyxes ſomewhat tomentoſe; down ſeſſile.

DESCRIPTIONS, &c.

1. Height not more than ſix inches. Flowers yellow[a]. Gouan (illuſtr. 57.) joins it with the *Hieracium pumilum* of Linnæus.—Native of the mountains of Italy.

2. Stems not above a ſpan in height, having on them a few ſhort laciniate leaves. The root-leaves reſemble thoſe of Shepherd's-purſe, whence its name. The ſtems are divided at top into two, three or more peduncles, which are very ſlender and ſupport ſmall flowers. It is a perennial plant, and is found near Palermo, and in other places in Sicily[b]. Alſo in the county of Nice.]

[a] Ray. [b] Ibid.

3. This is an annual plant, putting out leaves next the root, nine inches in length, and almoſt two broad in the middle, of a light green colour. Stems a foot and half high, dividing into many branches, and having leaves of the ſame form with the others, but ſmaller and ſeſſile. The flowers are produced at the ends of the branches. The outer ſeries of calycine leaflets are bent down, turn up again, and are bent in at their extremities.

[Leaves lanceolate, ſmooth, with a few teeth. The ſmall branches narrower at the baſe; one as it were growing out of the other. Flowers yellow, purpliſh at the baſe, but the florets in the diſk almoſt wholly dark purple. Seeds columnar, crowned with a very minute ciliate edge, and two long ſimple briſtles [c]. The outer calyx is longer than the corolla [d].—Herman and Miller have miſcalled the diſk black; but Parkinſon and Ray long ſince ſaid that *it is atropurpureus* or very dark purple.]

There are two varieties, one in which the flowers are deep yellow; and the other in which they are of a ſulphur colour inclining to white, but both have a very dark purple bottom or middle, and make a pretty appearance in the flower-garden. They flower in june and july, and the ſeeds ripen in autumn.

[Native of the South of Europe. Introduced about 1620, by Mr. William Boel [e].

4. *α.* Root thick. Leaves lyrate, angular, toothed, ſcabrous. Stem ſhort. Branches long, naked, bifid or trifid, one-flowered. Bractes of the peduncles ovate, ſolitary, concave, entire, pale. Flowers yellow. Involucre the length of the calyx, compoſed of five or ſix ſpreading, ovate, obtuſe, concave, membranaceous, pale leaflets.

β. Differs manifeſtly from the other in its leaves, but the flowers unite them [f].

α. Said by Linneus to grow in Switzerland, which Haller denies, Hieracium montanum rapifolium of Bauhin belonging to Crepis biennis.

β. Native of Apulia.]

5. This is an annual plant, which ſends out many oblong pointed leaves next the root; they are five inches long, and almoſt two broad at their baſe, leſſening gradually to a point; the upper part is ſlightly indented, but the lower is entire. The ſtems are ſtrong and upright, two feet high, dividing into three or four erect branches, terminated by pale-coloured flowers, incloſed in a ſtrong hairy calyx, which contracts cloſe towards the top. The ſtem-leaves are of the ſame form with the others, embracing, ſlightly indented towards the baſe, hairy and rough. [Receptacle concave, deeply alveolate, the edges of the cells ciliate. Seeds very long, with numerous rugged ſtreaks, of a pale bay colour, from a club-ſhaped baſe leſſening gradually into the ſtipe. Down capillary, white, much ſhorter than the ſeed: ſtipe ſubulate-ſetaceous, rugged, the length of the ſeed. The ſtructure is the ſame in the ſeeds of *veſicaria, rubra, foetida*, &c.[g]]

Native of the Alps. It flowers in june, and the ſeeds ripen in autumn.

6. Root annual. Root-leaves many, lanceolate, deeply jagged. From theſe ariſe the ſtalks, which are a foot and half high, dividing into many ſlender branches, each terminated by one large flower, of a red colour. [Down ſtipitate as in C. alpina and veſicaria. The calyx nods before the flower opens [h].

Native of Italy. Cultivated in 1632, by Mr. Nicholas Swayton [i].

7. Stem a foot or eighteen inches in height, erect, round, angular-grooved, rough with hairs ſtanding out. Root-leaves petioled, forming a tuft; ſtem-leaves claſping, deeply pinnatifid almoſt to the nerve; the outmoſt ſegment triangular, acute, toothletted, the ſide ones broader above, the loweſt linear, a little curved, all toothed, hoary green, hairy, ſcabrous. The ſtem and branches appear panicled with the flowers. Calyx cylindric, conſiſting of parallel ſcales, whitiſh on the outſide, ſet with very ſoft hairs, and at the baſe a few ſmaller ſcales. Flowers yellow, the ſize of thoſe in *C. tectorum* [k]; purple on the outſide, nodding before they open. Seeds very long and ſlender, bearing the down on a long ſtipe [l]. Receptacle ſomewhat hairy [m].

Villars remarks, that this plant varies in ſize, form, colour, and ſmell; but that in all the varieties the root is fuſiform; the ſtem rough, channelled and branched; the leaves aſh-coloured and more or leſs indented at the baſe; that it has commonly the ſmell of bitter Almonds, eſpecially the calyx when bruiſed; that the florets are red on the outſide; the ſeeds fuſiform, and the egret on a ſtipe.

Linneus following Tournefort, attributes the ſmell of bitter Almonds to the leaves; Haller more juſtly gives the plant a bituminous ſcent. Ray ſays that *this* and the foregoing have a ſtrong ſcent of Caſtor. To me the flowers always ſeemed to have the ſmell of Opium.

Native of France, Germany, Switzerland, Auſtria, Piedmont; England, near Cambridge, Banſtead downs in Surry. Charlton, Northfleet and Greenhithe in Kent. Near Swaffham in Norfolk.

Petiver calls it Caſtor Hawkweed.

It flowers from june to auguſt. Biennial. Linneus makes it an annual.

8. Stem naked, branched, rough with ſubulate, ſtiff, ſcattered, ſpreading briſtles. Flowers almoſt cymed on ſtiff pedicels, ſubſeſſile, alternate, except the laſt. Calyx ſmall, ovate, toruloſe, hiſpid; the outer ſhorter, with ovate, membranaceous, deciduous leaflets.

Native of Sicily, the Levant and Paleſtine [n].

9. Annual. Stem half a foot high, erect, ſtriated, ſcabrous, branched. Leaves ſmooth and even. Peduncles elongated, ſcabrous, one-flowered, naked. Outer calyx compoſed of very many linear, obtuſe leaflets, half the length of the calyx, unequal at the inſertion: inner cut into thirteen parallel parts, each of which is a boat-ſhaped, compreſſed leaflet, the back hiſpid with little barbed prickles. Corolla *yellow*, purpliſh on the outſide. All the ſeeds have a hairy down [o].

10. Perennial. Stem ſtiff, two feet high, ſtriated, hiſpid. Leaves lanceolate-ovate, ſubruncinate, toothed more and more towards the baſe, ſcabrous underneath on the nerves: the lower on winged toothed petioles. Peduncles one-flowered, leafleſs, ſtrict, thicker towards the flower. Seeds brown-purple.

Compare Hieracium pyrenaicum with this [p]. Gouan combines varieties *β* and *∂* of that Hieracium with this ſpecies.

Native of Siberia, Switzerland, and perhaps the Pyrenees.

Introduced 1773, by John Earl of Bute. It flowers in july and auguſt [q].

11. This is a very common plant, of an aſh-coloured green. Stem angular-furrowed, with branches as long as the ſtem. Root-leaves as in common Dandelion (*Leontodon Taraxacum*): ſtem-leaves as in *Leont. autumnale*, with the teeth of the baſe upright and longer: branch-leaves entire, linear, ſubſagittate with the edges rolled back. The flowers never nod, and have the appearance of thoſe of *Lapſana*. Calyx furrowed, ſprinkled longitudinally with clammy hairs. Styles where they riſe above the anther brown, which is a ſingular character. The plant in other reſpects, liable to many variations [r]. In a rich ſoil, appearing as figured by Tabernæmontanus (Ger. 228. 2. *W.*): in a poor ſoil, a foot in height, with linear leaves, ſomewhat toothed, reſembling thoſe of *Plantago Coronopus*, (as in Gmel. 2. 6.): or only a hand's breadth high, with jagged leaves like thoſe of Dandelion [s].

[c] Linn. ſpec. [d] Linn. ſyſt. [e] Hort. kew.
[f] Linn. ſpec. [g] Gaertner. [h] Linn. ſpec.
[i] Hort. kew. from Johnſon's iter Cantianum.
[k] Pollich. [l] Haller. [m] Leers. [n] Linn. ſpec.
[o] Linn. mant. [p] Linn. ſyſt. [q] Hort. kew.
[r] Linn. ſpec. [s] Linn. ſuec. and Stokes in With.

Root annual; Relhan alone says perennial: ſimple, with few fibres, deſcending, yellowiſh, (very long and taper). *Stem* from one to two feet high or more, (Haller ſays four); upright, ſmooth, or a little hairy, eſpecially towards the baſe, often purple, leafy. *Leaves* very variable, ſmooth or ſlightly hirſute on both ſides (with bifid hairs, *Scop.*); thoſe next the root very like Dandelion leaves, but narrower and the midrib purple on the upper ſide; thoſe of the ſtalk claſping, pointed, and variouſly toothed. Flowers yellow, in a kind of looſe corymb. Inner *calyx* ſubcylindric; ſcales upright, equal: ſcales at the baſe five or more, ſubulate, ſhort, unequal, looſe, and like the others ſlightly hiſpid. *Florets* five-toothed, and moſtly purple beneath. *Seeds* twenty or more in each head, brown and finely grooved: down longer than the ſeed, ſeſſile and ſimple, or ſubplumoſe only when highly magnified[t]. There are ſmall ſubulate bractes on the fruit-ſtalks, at ſmall diſtances beneath the flowers[u].

The flowers, heads, and ſeeds of this plant are ſmaller than any Engliſh Hawkweed, except the *Hyoſeris* and *Hypochæris glabra*. To this we may add, the ſtructure of the calyx, and the ſtem-claſping leaves[x].

The flowers expand about four in the morning, and cloſe about noon[y].

Native of Europe, in paſtures, by way-ſides, on banks and on walls: flowering from june to ſeptember.

Called by our old writers *Yellow Succory*, *Succory-Dandelion*, and *Succory-Hawkweed*.—Petiver calls it *Hawk-beard*, and Dr. Withering has adopted this name for the genus.

12. *Stem* angular, ſcabrous, from four to ſix feet high, brittle. All the *leaves* lyrate-pinnate, hiſpid beneath. *Calyx* furrowed, muricated longitudinally with tender prickles[z].

The lower ſcales ſmooth, patulous; the upper erect, rounded at the back and hiſpid. Receptacle alveolate, the edges of the cells ciliate. Seeds oblong, roundiſh, ſtriated, ſmooth, yellow or ferruginous, more ſlender at top but not ſtiped. Down ſeſſile, capillary, ſnow-white, deciduous[a].

Flowering branches divaricate, bearing ſeveral flowers on ſeparate peduncles. Beneath the lower branches leaves ſimilar to the ſtem-leaves; beneath the upper linear-lanceolate. The peduncles have lanceolate bractes. Leaves of the inner calyx lanceolate. Seeds furrowed, crowned with a ſeſſile down, not plumoſe, a little longer than the calyx[b]. All the ſcales of the calyx ſlightly cottony, with only here and there a ſcattered, ſhort, briſtly hair[c].

Native of Scania, Switzerland, Italy, Germany; England, paſtures in a calcareous ſoil, as in Kent about Northfleet, and between Sittingbourn and Rocheſter; in Cambridgeſhire about Linton, *&c.* Biennial: flowering in july and auguſt.

The flowers cloſe between three and four in the afternoon[d].

This and the preceding ſpecies, together with Leontodon hiſpidum, hirtum, and autumnale, have been combined by Hudſon, under the name of *Hedypnois*.

13. Root-leaves lanceolate, obtuſe, ſmooth, ſomewhat toothed; ſtem-leaves lanceolate, haſtate, nearly embracing the ſtem, very entire, acute, ſmall. Stems a ſpan in length, erect, filiform, ſubdichotomous. Flowers ſmall, yellow. The calyxes only tomentoſe[e]; but even they are ſmooth according to others[f].

Native of France, Switzerland, Siletia, and Italy.

Linnæus doubts whether this may not be a variety of the next ſpecies; and Gouan does not heſitate to make them one and the ſame.

According to Gærtner, it differs from *Hieracium* only in the calyx; which, when ripe, reſembles much that of *Hyoſeris minima*; is ventricoſe, toruloſe, and ſcarcely calycled. Receptacle obſoletely ſcrobicular. Seeds regularly columnar, deeply grooved, rufeſcent. Down capillary, ſeſſile, half as long again as the ſeed, deciduous.

14. Annual. Stem a foot high, ſomewhat angular, ſmooth and even; branches but few, round and ſpreading. Root-leaves lyrate-toothed, naked, ſmooth, toothletted, ſcarcely ciliate: ſtem-leaves claſping, haſtate, linear-lanceolate, with a purple ſtain on the lower diſk, and the ears very much toothed at the baſe: branch-leaves linear, with one tooth at the baſe. Peduncles long, naked, aſcending, one-flowered, ſcarcely thickened at the end. Calyxes mealy, not nodding before they flower: the calycle linear. Corolla yellow, purple beneath before it expands[g].

This is united with the preceding by ſeveral authors, as Vaillant, Haller, Gouan, and Villars.

Native of France, the Palatinate, Siletia, Italy, Siberia. Flowering in june.

Introduced 1772, by Monſ. Richard[h].

15. Calyx ſmooth and even, narrow, angular, with very minute green ſcales at the baſe. Annual. Native of France and Italy[i].

It flowers in july and auguſt: and was cultivated in Chelſea garden, in 1739[k].

Krocker has a long deſcription of it.

β. is thus deſcribed by Retzius.—Root annual, branched. Stem upright, branched, from two to five feet high, grooved, ſmooth, panicled. Lower leaves lyrate, upper oblong-cordate, the reſt haſtate; all ſeſſile, ſinuate-toothed, pubeſcent, eſpecially the uppermoſt, which are linear and entire. Flowers panicled, yellow, on naked pedicels. Calyx cylindric, ſmooth, ten-leaved; leaflets linear, keeled; calycle of five ſhort margined ſcales. Florets twenty-four, a little higher than the calyx. Receptacle naked. Seeds oblong, *cylindric*, very ſlightly ſtreaked. Down ſimple, ſeſſile.

16. Annual. Stem a foot high, branched, ſomewhat hairy, erect. Root-leaves obovate-oblong, toothed, ſomewhat hairy: ſtem-leaves claſping, runcinate, ſomewhat hairy, with elongated teeth even at the baſe: upper leaves ſubhaſtate. Flowering branches elongated, naked, ſmooth and even, two-flowered or bifid at the end. Outer calyx very ſhort, acute; inner having *eight* or ten leaflets, with one or two harmleſs ſpines in the middle. This agrees with *C. pulchra* in its ſize and the ſmallneſs of its flowers; it differs in having the leaves runcinate, toothed and ſomewhat hairy, whereas in the other they are entire, a very little toothed and viſcid. Some of the ſynonyms given under *C. pulchra* belong probably to one, and ſome to the other.—This is a native of Italy[l].

17. Perennial. Stems ſeveral, twice or thrice dichotomous, with a ſeſſile leaf at each diviſion of the branches. Root-leaves elliptic, gradually leſſening into a leafy petiole, thickiſh, toothed, ſeldom quite entire. Stem-leaves half embracing, rougher, ſharper, with a more evident prickle. Receptacle alveolate. Calyx nearly conic, toroſe; inner ſcales roughiſh, *duſky* at the *end*, whitiſh about the edge, boat-ſhaped at their origin, at firſt erect, but afterwards ſpreading; ſome of the outer ſcales longer than the reſt and preſſed cloſe to the others. Peduncles naked, thickened under the flower, having a ſmall ſcale near the calyx. Florets five, the length of the calyx. Down ſimple, ſeſſile, about the length of the ſeed. When the ſeed is ripe, the calyx is wholly reflected[m].

The deſcription by Monſ. Villars contains ſome particulars not mentioned by Allioni, and differs in many reſpects from his.—The ſingle ſtem bears two or three flowers, ſometimes one only, but is commonly divided *into two* or three peduncles; it is ſtraight, firm, grooved and villoſe from the middle upwards; and the branches are ſpreading. Leaves at firſt entire, afterwards toothed and even pinna-

tifid; they are white and villoſe, four or five inches long, and an inch wide: there are only two or three ſhorter ones under the branches. Peduncles a little thicker at top, with hairs in part glandular. Calyx pretty large, dilated and having a ſingle ſcale at the baſe; otherwiſe ſimple, with the ſcales imbricate as in *Hieracium*, but very ſenſibly membranous at the edge, as in *Hypochæris*. Flowers large, pale yellow or whitiſh, compoſed of a great number of florets. Seeds diminiſhing into a ſtipe at top. Egret very white, hairs ſimple or a little toothed, but ſhort and numerous. Receptacle a little villoſe.

Native of France and Italy.

18. Native of the Azores. Perennial. Flowering in july and auguſt. Introduced 1778.

19, 20. Natives of Madeira. Introduced 1777, from Mr. Francis Maſſon.—The firſt is biennial, and flowers in june; the ſecond is annual, and flowers in auguſt and ſeptember[a].

PROPAGATION AND CULTURE.

Few of theſe plants are commonly cultivated, and ſome of them are weeds in gardens and paſtures. The third and ſixth ſpecies appear as annuals in the flower-garden. Theſe and any of the other ſorts may eaſily be propagated from ſeeds;] which ſhould be ſown in the ſpring, on the borders of the flower-garden where they are deſigned to remain, ſo that if ſix or eight ſeeds are ſown in each patch, when the plants come up, they may be reduced to three or four; and if theſe are kept clean from weeds, they will require no other culture, excepting the putting ſmall ſticks down, to faſten the ſtalks to prevent their being broken by winds or rains. If the ſeeds are ſown in autumn, or permitted to ſcatter, the plants will come up and live through the winter without ſhelter, and theſe will flower early in the ſpring.

[The three laſt ſpecies require the protection of a greenhouſe. All the others are hardy.

DESCRIPTIONS, &c.

[Theſe are ſmall trees, with large leaves, either ſingly alternate (2) or in alternate bundles (1). Flowers on the trunk or branches ſubſolitary.—Juſſieu doubts whether C. jaſminoides of Lamarck, Cateſb. car. 1. t. 59. be of this genus.

1. This tree grows to the height of about twenty feet, and is eaſily diſtinguiſhed from all others by its peculiar appearance. It divides at top into very long, thick, ſcarcely ſubdivided branches, ſtretching out almoſt horizontally, adorned with leaves diſpoſed in bundles or tufts ſcatteringly at irregular diſtances. The wood is light and pliant. The bark is unequal and aſh-coloured or whitiſh. The leaves are uncertain in their number from the ſame knot or tubercle; they are oblong, attenuated at the baſe, on very ſhort petioles, acute, entire, ſhining, veined, bright green, four or five inches long. Peduncles one-flowered, ſolitary, ſcattered over the older branches, and frequently on the trunk itſelf three inches above the ground. Flower large, ſometimes entirely green, but often differently variegated with purple red and yellow; it does not wither, but becomes putrid, and in that ſtate exhales a cadaverous, very naufeous and intolerable ſtench. It happens not uncommonly, that there are five fertile ſtamens, and in that caſe three of them are longer than the other two. The form of the fruit varies on different trees, being ſpherical, ſpheroidal, or ſhaped like a bottle; it differs alſo in ſize from two inches to a foot in diameter. Theſe, however, if they are no more than varieties, are very conſtant[a].] They are covered with a thin ſkin of a greeniſh yellow colour when ripe, and under this is a hard thin woody ſhell, incloſing a pale yellowiſh ſoft pulp, of a tart unſavoury flavour, ſurrounding a great number of flat ſeeds. The ſhells, cleanſed of their pulp, deprived of the outer ſkin, and dried, are uſed in the Weſt Indies for drinking cups, tipped with ſilver, and with handles faſtened to the neck; the long ſmall fruit is formed into ſpoons and ladles; that which is round, is cut through the middle, and uſed as cups for chocolate: in ſhort theſe ſhells are converted into a variety of domeſtic furniture. [They are frequently large enough to hold a gallon or more of fluid: and they are ſo thin and cloſe, that they ſerve to boil water as well as an earthen pot, and *will bear the fire* equally, on repeated trials. The thicker parts are frequently uſed for button-moulds, in all the colonies[b]. The Caribbs engrave the outſide with a variety of groteſque figures, which they ſometimes colour black or red[c]. The pulp is eaten by the negroes occaſionally, but is not looked upon as either agreeable or wholeſome. It is however much uſed by way of poultice[d]; and a ſyrup made of it is in much requeſt among the natives in diſorders of the breaſt, in contuſions and inward bruiſes[e]. The wood being very tough and flexile, is very fit for the coachmaker[f];] and is frequently uſed for making ſaddles, ſtools, and other furniture. The leaves and branches are eaten by cattle in times of ſcarcity; as is alſo the pulp of the fruit.

It is a native of Jamaica and all the Leeward iſlands, [chiefly in the low lands; and alſo of the neighbouring continent.—It was introduced here in 1690, by Mr. Bentick[g].

2. The trunk of this tree is middle-ſized, unarmed, ſmooth and even. The branches ſubdivided, erect, not ſpreading, ſtiff and ſtraight, angular, even. Leaves oppoſite, alternate or ſcattered, never in tufts, larger, broad, ovate, with a ſhort point, quite entire, nerved, abſolutely ſmooth, ſhining above, paler beneath. Petioles ſhort, thick, ſmooth. Peduncles two to five, terminating, ſhorter than the leaves, longer than the petioles, one-flowered. Corollas nodding, the ſize of the preceding, but more duſky; the baſe of the tube and throat is white, the

[a] Jacquin. [b] Browne. [c] Jacquin. [d] Browne. [e] Jacquin. [f] Browne. [g] Hort. kew.

belly red, the border pale, the segments dusky. The fruit is pedicelled, ovate-oblong with a short point, one-celled.

It differs from the preceding in its habit, the uprightness of its branches, its flat, oblong, shining, coriaceous leaves, terminating flowers on longer pedicels, corolla with the border entire, and ovate, acuminate fruit. It flowers the whole year[b].

Native of Jamaica, in dry rocky places near the coast.] Mr. Miller had the fruit from Dr. Houstoun, who found it growing naturally in plenty at Campeachy. According to him, it seldom rises more than fifteen or twenty feet high, the trunk is upright, covered with a white smooth bark, the leaves are three inches in length, and one inch and a quarter broad, of a deeper green than the preceding, the flowers smaller and deeper-coloured, the fruit round or oval, varying much in size, the shell so thin and brittle as to be unfit for any purposes to which that of the former is employed, the seeds much thinner, and the pulp of a deeper yellow. The wood is very hard and white.

PROPAGATION AND CULTURE.

These trees being too tender to live abroad in England, require a warm stove to be preserved here. They are easily propagated by seeds, which must be procured from the countries where they grow naturally; the way is to have the entire fruit sent over when fully ripe; for when the seeds are taken out of the pulp abroad, if they are long in their passage they will lose their growing quality before they arrive, as I have often experienced. These must be sown on a good hot-bed in the spring, and when the plants are fit to remove, they should be each planted into a small halfpenny pot filled with light sandy earth, and plunged into a hot-bed of tanner's bark, observing to shade them from the sun till they have taken fresh root; when they must be treated in the same manner as other tender plants, which are natives of the same countries. In winter they must be placed in the tan-bed of the bark-stove, and during that season should have but little water; in summer they will require to be gently watered two or three times a week, according to the warmth of the season; and in hot weather they should have a large share of air admitted to them. With this management the plants will make great progress, and their leaves being of a fine green, they make a pretty variety in the stove, but have not as yet flowered in England.

DESCRIPTION, &c.

1. This is a small plant, and very shrubby. Root long, slender, jointed, white. Hence arise several stems, not fewer than five, long, slender, round, whitish, whence at short intervals spring many slender short twigs, surrounded on every side with many very small leaves, the size and form of a lentil: the whole forming a very close round shrub. The small flowers come out at the ends of the twigs. The fruit is small, oblong and cylindric, of the size and somewhat of the form of a grain of wheat. The whole plant is white, and has a salt taste[1].

Native of Crete, on the sea shores; and at Ostia near Rome.

2. It differs from the preceding in having the corolla snow-white, hairy on the outside, especially at the ends of the segments, and four seeds in the capsule. In other respects it is like the other.

Native of the East Indies, in salt marshes; observed there by Koenig[k].

Crimson Grass-Vetch. See *Lathyrus Nissolia*.

COR. bell-shaped. *Petals* six, oblong, erect, spreading at the tip.
STAM. *Filaments* ten, erect, united at bottom. *Anthers* ovate, erect.
PIST. *Germ* superior, ovate. *Style* subulate, a little longer than the stamens.
PER. *Capsule* coriaceous, obtusely three-cornered, one-celled, gaping elastically at top.
SEEDS three, roundish.

ESSENTIAL CHARACTER.

Cal. none. *Cor.* bell-shaped, six-petalled. *Caps.* one-celled, gaping elastically at top.

SPECIES.

1. Crinodendron Patagua.
Cavanill. diss. 9. *p.* 300. *ic. tab.* 158. *fig.* 1.
Molina hist. Chil. p. 179.
Lily-tree with opposite, lanceolate, serrated leaves.

DESCRIPTION.

This, which is the only species at present known, is a superb, ever-green branchy tree, with a body of seven feet in diameter. The leaves are opposite, a great deal longer than the petioles, of a bright green, lanceolate, and serrated: there are no stipules: the flowers are scattered and axillary, the peduncles one-flowered; the flowers having the odour of lilies. The seeds are of the size of a lentil. It is a native of Chili: Joannes Ignatius Molina was its first discoverer and describer.]

CRINUM. (*A name in Pliny.* Κρινον *of Dioscorides. Derivation unknown.*)
Lin. gen. n. 405. *Reich.* 438. *Schreb.* 553.
Bulbine. *Gærtn.* 13.
Class. 6. 1. Hexandria Monogynia.
Nat. order of *Spathaceæ.—Narcissi.* Juss. 54.

GENERIC CHARACTER.

CAL. *Involucre* spathe-form, two-leaved, oblong, umbelluliferous, after gaping reflected.

[1] Alpin. [k] Retz.

COR.

Cor. one-petalled, funnel-form; *Tube* oblong, cylindric, inflected. *Border* six-parted: *divisions* lanceolate-linear, obtuse, concave, reflected, of which the three alternate ones are distinguished by a hooked appendicle.

Stam. *Filaments* six, subulate, from the base of the border, of the length of the border, converging. *Anthers* oblong, linear, rising upwards, incumbent.

Pist. *Germ* inferior. *Style* filiform, length of the flower. *Stigma* three-cleft, very small. (simple or three-cleft. *J.*)

Per. *Capsule* subovate, three-celled. (covered with the calyx. *J.*)

Seeds several.

Obs. *It differs from* Pancratium *only in the want of a nectary.* L'Herit.

ESSENTIAL CHARACTER. Syst.

Cor. funnel-form, monopetalous, six-parted: three alternate segments uncinate. *Germ* at the bottom of the corolla, covered. *Stam.* distant.

ESSENTIAL CHARACTER. Lin. fil. in Hort. kew.

Cor. funnel-form, half-six-cleft: tube filiform; border patulous recurved, segments subulate channelled. *Filam.* inserted in the throat of the tube, distinct.

C. asiaticum. *Mill. dict. n.* 2. *fig. t.* 110.
Lilio-asphodelus. *Comm. rar. t.* 15.
Leaves lanceolate cartilaginous-crenulate, the end produced and unfolded; flowers sessile; tube longer than the border.

[4. Crinum tenellum.
Lin. syst. 319. *suppl.* 194. *Jacqu. ic. rar. Plnk. alm. t.* 225. *f.* 2. (Sisyrinchium.)
Spathe many-flowered, corollas equal, leaves filiform.

5. Crinum lineare.
Lin. syst. 319. *suppl.* 195.
Leaves linear; corollas bell-form, with two segments narrower than the rest.

6. Crinum nervosum.
L'Herit. sert. 8. *n.* 3. *Rumph. amb.* 6. 160. *t.* 70. *f.* 1. (Cæpa.)
Leaves roundish nerved, filaments widened at the base.

DESCRIPTIONS, *&c.*

1. Root solid, turbinate, surrounded with long branching fibres. Stem short, thick, coated, white, single. Leaves three feet long, three inches wide, subulate-linear, erect, striated, thick, imbricate. Scapes axillary, round, equal to the leaves. Flowers white, large, in a simple flat umbel. Common involucre oblong. All the segments of the corolla are equal, and not hooked. Stamens distant. Capsule roundish, irregularly lobed [a].

Linneus observes, that the leaves are equitant in two rows. Corolla purple with white edges. Stamens declining: according to L'Heritier they are scarcely so. Bulbs are generated between the capsules. Native of Malabar, Ceylon, Tranquebar, Cochinchina, &c.

Rumphius extols the efficacy of the roots against poison both of serpents and arrows, in œdematous swellings, &c.

Gærtner makes this a distinct genus under the name of *Bulbine*, affirming that it differs as much from Crinum, as Alstroemeria from Hemerocallis. For Crinum has a superior, prismatic, three-valved capsule, and very small seeds, perpendicularly imbricate, and terminated by a membranaceous wing, as in Pinus. Whereas the capsule in this is inferior, membranaceous, inflated and valveless: the seeds three-sided, with membranaceous angles: the divisions of the corolla also are not hooked at the end. But his Crinum is our *Agapanthus umbellatus.*

*2. Flowering stem a foot and half in height, the thickness of a finger, slightly compressed, coming out, not from the centre of the leaves, but on one side. Leaves two feet and more in length, and a hand broad, furrowed on the upper surface, and keeled on the lower, smooth, stiff, light green, slightly waved on the edge, thickish, sharp-pointed, pierced with many largish pores. Flowers before they open pale yellow, but when open of a milky whiteness, and of no disagreeable smell: segments of the petals keeled; tube about two inches in length. Stamens long, bending in, white at bottom, but purple at top. Style shorter than the stamens, of a deeper purple colour. The flowers open successively, each lasting a day or two. Some very slender threads adhere to the involucre, and to the pedicels of the flowers [b]. Native of South America. Flowering in july and august. Cultivated 1732, in the garden of James Sherard, M. D. at Eltham [c].

3. The flower-stem arises immediately from the root, on the outside of the leaves, and is about two feet high; on the top are eight or ten flowers, in form of an umbel, closely joined at their base, but spreading above. They are of a beautiful white colour, and smell very sweet. The stamens are stretched out to a considerable length beyond the petals. After the flowers are past, the germ swells, and becomes an oblong bulb. The plants generally flower three or four times in a year, but at no regular season; as the petals are of a very tender texture, they do not continue in beauty longer than four or five days [d].

Native of the Spanish West Indies. Mr. Miller received roots of this and the foregoing species, at least as early as the year 1756, from Panama and Carthagena, probably some years earlier, and cultivated them in the Botanic Garden at Chelsea.

4. A plant less than *Ornithogalum minus.* Leaves radical, linear-filiform, of a finger's length. Scape filiform, columnar, the same length with the leaves. Flowers in an umbel, of three or four equal, filiform pedicels, an inch in length, from patulous erect: spathe linear, membranaceous: corolla the size of *Arenaria trinervia*, spreading a little; petals lanceolate, equal: stamens almost erect, a little shorter than the corolla: germ tricoccous: stigma often spiral, as in *Anthericum spirale.*—Found at the Cape of Good Hope, by Sparrmann [e]. According to the opinion of the younger Linneus and Solander, this is a *Leucoium*, or perhaps a new genus [f].

5. Flowers large, white. Found at the Cape by Thunberg [g].]

6. Leaves cordate-rounded, entire, acuminate, with concentric nerves. Scape many-flowered, many-leaved. Flowers on long peduncles. Tube of the corolla filiform; segments of the border acute, spreading. Filaments inserted into the throat, opposite to and shorter than the segments, straight, not declined. Native of the Philippine islands, observed by Monsr. Poivre [h].]

PROPAGATION AND CULTURE.

These bulbs are very ornamental plants for the stove. They are easily propagated by offsets, which the roots put out in plenty; or by the bulbs which succeed the flowers, and ripen perfectly here. These must be planted in pots filled with rich earth, and if plunged into the tan-bed in the stove, the plants will make greater progress and flower oftener, than when they are placed on shelves; though in the latter way they will succeed very well, provided they are kept in a good temperature of heat. The roots should be transplanted in the spring, and all the offsets taken off, otherwise they will fill the pots, and starve the old plants: they must be frequently refreshed with water, but it must not be given them too plentifully, especially in winter. These sorts flower at every season of the year, which renders them more valuable; for where there are many plants, there will be almost a perpetual succession of flowers, which emit a very agreeable odour.

DESCRIPTIONS, &c.

1. Perennial. Stems smooth and even, entirely simple. Leaves triternate, the middle one often five-leaved. Leaflets linear, acute, lucid. Petiole the thickness of the leaflet. Involucre five-leaved, involucels seven-leaved, short[1].]

It has a root composed of many strong fibres, which penetrate deep into the crevices of the rocks, sending up several fleshy succulent stalks, which rise about two feet high, with winged leaves, composed of three or five divisions, each of which has three or five thick, succulent leaflets near half an inch long; the foot-stalks of the leaves embrace the stalks at their base. The flowers are produced in circular umbels at the top of the stalks; these are of a yellow colour, and are succeeded by seeds somewhat like those of Fennel, but larger. This herb is pickled, and esteemed very comfortable to the stomach, and is agreeable to the palate; it provokes urine gently, removes the obstructions of the viscera, and creates an appetite; it is commonly used for sauce; it is gathered on the rocks, where it grows naturally, but the people who supply the markets with it, seldom bring the right herb, but instead of it they bring a species of Aster, which is called golden Sampire, but has a very different flavour from the true, nor has it any of its virtues. This grows in greater plenty, and upon the plain ground which is overflowed by the salt water; whereas the true Sampire grows only out of the crevices of perpendicular rocks, where it is very difficult to come at. It flowers in july, and the seeds ripen in autumn.

[Native of the rocky shores of the European ocean. In Britain, on Dover cliffs, Winchelsea, Rye, Southampton, the isle of Wight; on all the cliffs of the Cornish coast. The fields about Porth Gwylan in Caernarvonshire are covered with it. Furness in Lancashire. *Galloway* in Scotland.—Allioni informs us that it also grows on old walls in the Alps.—It is not only used as a pickle, but fresh as a pot-herb, by inhabitants of the sea-coast. Not only the *Inula crithmoides*, which Mr. Miller calls a species of Aster, is used for Sampire, but the *Salicornia* is the only Sampire known on the east coast, and is called *Marsh Sampire.* The inhabitants there must needs be surprised that the gathering of Sampire should be called a dangerous trade, when they pluck it at their ease as they walk on the sand. This, however, is tasteless, and has a tough string running through the middle; whereas the true Sampire has a warm aromatic flavour, without any impediment to the teeth in eating.—Mr. Pennant informs us that sheep and cows eagerly feed, and are said to grow fat upon it.

It has the name *Sampire* or *Sampier*, sometimes wrongly spelt *Samphire*, from the French *St. Pierre.* Gerarde says, it is by some called *Creshmarine*, which is also from the French *Crisse marine*; they likewise call it *Bacille maritime, Fenouil marin, Passe-pierre, Perce-pierre* and *herbe de St. Pierre*, evidently from the roots striking deep into the crevices of rocks. In Italian it is *Critmo, Finocchio marino*, and *herba di Santo Pietro.* In Spanish, *Hinojo marino.* In Portuguese, *Funcho marinho.* In German, *Meerfenchel, Seefenchel, Bacillen.* In Danish, *Soefenkel.* In Swedish, *Sjofenkal.*

2. Haller supposes this to be nothing else but *Athamanta Libanotis* growing old. Jussieu is of opinion that it is more nearly related to the genus Athamanta. It is a biennial plant, and a native of the Pyrenees.]—Mr. Miller doubts whether the Apium petræum f. montanum album of Ray's synopsis (which is Athamanta Libanotis) be distinct from this. He says it is of humbler growth; the leaflets broader, not so much cut on their edges, and of a paler green.

[3. This is a very smooth plant, a foot and half in height. Stem round, furrowed, erect. Leaves petioled; leaflets opposite, bijugous or trijugous, the outer edge decurrent, gradually dilating, lobed and toothed. Petioles dilated at the base, stem-clasping. The involucre and involucel have six or eight lanceolate leaflets. Flowers yellow. Seeds

[1] Linn. mant.

smooth,

ſmooth, furrowed, with a raiſed, even edge.—Found on the coaſts of Teneriffe and the Salvages, by Maſſon[a]. Biennial; it flowers in july, and was introduced in 1780[b].]

PROPAGATION AND CULTURE.

1. This plant is with difficulty propagated in gardens, nor will it grow ſo vigorous with any culture, as it does upon rocks; but if the plants are planted on a moiſt gravelly ſoil, they will thrive tolerably well, and may be preſerved ſome years. It may be propagated either by ſeeds, or parting the roots.

[It grows beſt when rooted in a wall, or on artificial rock-work.]

2. This is preſerved in a few gardens for the ſake of variety; it is propagated by ſeeds, which ſhould be ſown in the autumn where they are deſigned to remain, and will require no other culture but to keep them clean from weeds, and thin them where they are too [illegible].

[3. Propagated by ſeeds, and to be preſerved in the green-houſe or conſervatory.]

DESCRIPTIONS, *&c.*

1. Autumnal or officinal Crocus or Saffron has a roundiſh bulbous root as large as a ſmall Nutmeg, which is a little compreſſed at the bottom, and is covered with a coarſe, brown, netted ſkin; from the bottom of this bulb are ſent out many long fibres, which ſtrike pretty deep into the ground; from the upper part of the root come out the flowers, which, together with the young leaves, whoſe tops juſt appear, are cloſely wrapped about by a thin ſpatha or ſheath, which parts within the ground, and opens on one ſide. The tube of the flower is very long, ariſing immediately from the bulb, without any foot-ſtalk, and at the top is divided into ſix ovate obtuſe ſegments, which are equal, of a purple blue colour. In the bottom of the tube is ſituated a roundiſh germ, ſupporting a ſlender ſtyle, which is not more than half the length of the petal, crowned with three oblong golden ſtigmas, which is the Saffron; theſe ſpread aſunder each way. The ſtyle is attended by three ſtamens, whoſe baſes are inſerted in the tube of the petal, and riſe to the height of the ſtyle. This plant flowers in october, and the leaves keep growing all the winter, but it never produces any ſeeds here.

[Haller remarks, that the autumnal Saffron differs from the Spring Crocus, in having the ſtigma divided into three long ſegments, the ends of which are alſo trifid. Theſe three horns of the ſtigma are alſo odorous and aromatic, which is not the caſe in the vernal Crocus: and the flowers are much larger. Add to this, that the corolla does not vary much in colour from its high native purple, that they differ alſo in the root and leaves, the time of flowering, and the place of growth.

Not to enter into the controverſy whether the autumnal and ſpring Crocus be ſpecifically diſtinct or not; it is to be lamented that our knowledge is not yet far enough advanced to aſcertain the ſpecies of plants on all occaſions, and to place ſpecific differences on firm foundations. Here two plants are ſuppoſed to be varieties only, though they differ in all the circumſtances above recited: and yet Hemerocallis flava & fulva are kept diſtinct, though they differ only in ſize, in the colour of their flowers, and the time of flowering.

It is the caſe with Saffron, as with many other plants in common cultivation; the place where it grows ſpontaneouſly is not well aſcertained. Cavanille ſays it grows on rocks near the ſea ſide in Portugal[a]. Allioni affirms that it is indigenous of Savoy: but I can ſcarcely think that it is a native of any part of Europe, where we do not find that it ever produces ſeed. Bulbous plants being perennial, and rooting themſelves very firmly in the earth, have eſtabliſhed themſelves in moſt parts of Europe, ſo as to have the appearance of being natives, as if we ſhould take them to be ſuch, did we not know that they came originally from the Eaſt. I have no doubt but that ſome part of Aſia is the native country of the Saffron; and it was there it firſt acquired that high reputation in medicine, which it has now almoſt loſt in Europe. It is however ſtill cultivated in Italy, Sicily, Spain, France, Germany, Hungary, and very ſparingly with us in England.

That Saffron is indigenous of this country I cannot believe, though in Dr. Witherin's botanical arrangements, it is ſaid to be found about Halifax, and in a meadow near the copper-mills at Hayton. The indefatigable Ray affirms that nothing certain is known concerning its place of ſpontaneous growth, but that it is cultivated in moſt countries of Europe. In Cambridgeſhire, where the Saffron has been cultivated at leaſt two centuries, no wild plant was ever found, that I have heard of. In Hudſon's voyages (2. p. 164. edit. 1599.) indeed it is ſaid, that the ſoil in Herefordſhire yields the wild Saffron

[a] Linn. ſuppl. [b] Hort. kew.

[a] This is probably C. montanus 1. Cluſ. hiſt.

commonly

commonly; had this been true, it could hardly have eſcaped the curious reſearches of Ray; and beſides, our old authors called the vernal Crocus *wild* Saffron, appropriating the name *Saffron*, without any adjunct to the officinal ſpecies. Mr. Hudſon alſo has ſaid, "habitat in agro Cantabrigienſi & Eſſex-"ienſi—in pratis & paſcuis *paſſim*." But it certainly does not grow wild in either of thoſe counties; nor any where ſo common at leaſt as to juſtify the uſe of the word *paſſim*, the ſenſe of which Mr. Hudſon ſeems to have miſtaken.

It is commonly ſaid that Saffron was originally brought into England in the time of Edward III.; and that Sir Thomas Smith firſt introduced it into the neighbourhood of Walden in Eſſex.

The firſt of theſe aſſertions is very probable, but on what authority it reſts I have not been able to diſcover. It is mentioned by Strype, in his life of Sir Thomas Smith, and by Morant, in his hiſtory of Eſſex. But the firſt of theſe writers refers to Camden's Britannia; and the ſecond, to Ray's hiſtory, and the Philoſophical Tranſactions; in none of which books do I find any mention of the firſt introduction of Saffron into England. Mr. Gough, in his late edition of the Britannia, has alſo retailed the ſame report, but gives only the ſame references that Morant had ſet down before.

In Hackluyt's voyages (edit. 1599. 2. 165.) the firſt introduction of the Saffron into England is aſcribed to a pilgrim, who purpoſing to do good to his country, ſtole an head of Saffron, and hid the ſame in his Palmer's ſtaff. This ſtory carries a very legendary ſound with it; and being given only as a matter reported at Saffron Walden, may not perhaps obtain much credit.

That Sir Thomas Smith introduced Saffron into the neighbourhood of Walden, is a fact by no means well eſtabliſhed. None of the writers of this great man's life, mention any thing of the matter, except Strype; and he only ſays, "whether it was firſt "brought thither by this Knight's induſtry (being "a great planter) I know not." Certain it is, that Saffron was well known at Walden in 1582, in which year Hackluyt gave the remembrances for maſter S. (voy. 2. 164.): and if it be true, as I have been informed, that the corporation of Walden bear three Saffron plants in their arms; their charter having been granted, and probably their arms, in the third year of Edward VI.; it may be preſumed that the town was then famous for the cultivation of this plant.

Eſſex, however, was not the only county in which Saffron was then cultivated. Herefordſhire is particularly mentioned as that which yielded the beſt in all England: Mr. Houghton (in 1698) ſays, that he had ſeen ſome excellent Saffron from that county: and if we may believe Lyte, in his tranſlation of Dodoen's herbal (p. 155. edit. 1619.) it grew plentifully in ſome places of England and Ireland.

However this may be, Saffron was abundantly cultivated near Walden, at the end of the ſixteenth, and beginning of the ſeventeenth century. At what time it began to migrate into the neighbouring province, and at length finally quitted its primæval ſeat, I cannot preciſely aſcertain; but doubtleſs it was gradual, as its preſent decay in Cambridgeſhire has been. It ſhould ſeem as if in 1582 Saffron grew in both counties, and was then not much encouraged: for Hackluyt (2. 164.) ſays "if a vent "might be found, men would in Eſſex about Saf-"fronwalden and in Cambridgeſhire revive the "trade, for the benefit of ſetting the poor on "work."—Gerarde alſo (1597) informs us, that "Saffron groweth plentifully in Cambridgeſhire, "Saffron Walden and other places thereabout, as "corne in the fieldes." Camden (1586, &c.) makes no mention of Saffron as growing in Cambridgeſhire; but only obſerves that the fields all about Walden make a pleaſant ſhow with it. Speed, in his maps (1614) mentions it as growing with gain and increaſe in the north part of Eſſex.—From Blith's Engliſh improver improved (edit. 1653. p. 249.) we learn that "the Saffron country is on "one ſide and nook of Eſſex, and ſome part of "Suffolk; and at Saffron Walden and betwixt that "and Cambridge is very much of it in their com-"mon fields."—Robert Turner, in his Britiſh Phyſician (edit. 1664. p. 284.) ſays, that "it is "plentifully manured in fields in Eſſex and Cam-"bridgeſhire."—And Robert Lovell, in his Compleat Herball (1665. p. 377.) aſſigns Cambridgeſhire, Saffron Walden, &c. as the places of growth of Saffron.—Mr. Ray, in his catalogue of Cambridgeſhire plants (1660), had ſet down Saffron (art. Crocus) as cultivated in that county: and in the liſts of plants with which he furniſhed Biſhop Gibſon for his edition of Camden's Britannia (1695), he ſays, that "it is planted and cultivated about "Walden plentifully; and in Cambridgeſhire fre-"quently."—Dr. Moriſon (1680) aſſures us, that Saffron is no where better or more flouriſhing than in England, eſpecially in Hereford[illegible]re and Hampſhire, and about Saffron Walden, where it is abundantly cultivated.—And Mr. Houghton (1698) affirms, that the chief place in the world for Saffron, is Walden in Cambridgeſhire [Eſſex]; from whence comes the great quantities. *Collect.* 2. 332.—James Douglas, M. D. (in Philoſ. tranſact. n° 380. abr. 6. 311.) aſſerts that "Saffron has grown formerly in ſe-"veral counties of England, but that it then grew "moſt plentifully in Cambridgeſhire. He employed "proper perſons between the years 1723 and 1728 to "make obſervations on the culture of Saffron; and "aſſigns the place of its growth at that time, to all "the large tract of ground that lies between Saf-"fron Walden and Cambridge, in a circle of about "ten miles diameter."

Profeſſor Bradley, in 1724, ſays that the former of theſe places was once the chief market for it, but that of late years we find it cultivated in the grounds about Cambridge.

About this time it ſeems to have quitted the immediate neighbourhood of Walden, and to have migrated weſtward, nearly into the country where I found it in the year 1752. That is, in the pariſhes of Hinxton, Ickleton and Triplow, bordering on the Roman way, called the Ikenild ſtreet; and weſtward of theſe, to Gogmagog hills, in the pariſhes of Duxford, Newton, Harſton, Hauxton, Great and Little Shelford, Sawſton, Stapleford, and even as far as Fulborn, which is to the north of the hills; all in the county of Cambridge.

This plant, having given a prænomen to the town of Walden, might probably be ſuppoſed to have been cultivated there, long after it left the neighbourhood: but as we cannot doubt the accuracy of Mr. Ray, that event muſt have happened after the year 1695; and probably before 1723. The villages, however, of Ickleton and Hinxton are not above ſix miles diſtant from Saffron Walden.

The quantity of land under Saffron has been gradually leſſening during the laſt twenty or twenty-five years; owing, as it is thought, at firſt, to the lowneſs of the price, occaſioned by the great importation of foreign Saffron. It is now confined to two or three pariſhes only, of which Stapleford is one; and if ſome means are not uſed to encourage it, the cultivation of Saffron will probably ſoon be entirely loſt in this country.

Whether Saffron be of any national conſequence, I am not a competent judge; I only know that when the culture is entirely dropped, it will be no eaſy matter to revive it. Formerly the ſuperiority of Engliſh Saffron has been much celebrated, but lately it has been decried. This is not owing to our commodity being inferior to what it was; for it has at all times come out of the hands of the growers pure and genuine; but perhaps the foreign dealers are now wiſe enough to leave off their old ſophiſtications with baſtard Saffron or Safflower, Marygolds, &c.; and if ſo, their commodity, coming from a warmer climate, may have the ſuperiority. I only know that if the foreign Saffron can be afforded cheaper, it will be encouraged, without attending to its

its quality; and that I have very lately experienced a very ſenſible difference between the foreign and Engliſh Saffron, greatly to the advantage of our own.

Our modern European term of *Saffron* is from the Arabic *Sabuſaran*; hence the Mooriſh and Spaniſh *Azafran*, *Azafraon*, *Safra*: the Italian *Zaffarano*, the German, Daniſh, Swediſh and French *Saffran*, or *Safran*, &c.

The varieties of autumnal Crocus are few, becauſe it produces no ſeed in our climates, whatever it may do in the Eaſt.] Mr. Miller has only four. 1. Sweet-ſmelling, which is his ſecond ſort, and our variety β. He ſays, that it grows naturally on the Alps and Swiſs mountains; that the root is ſmaller and more compreſſed, that the flowers riſe with a ſhort ſtalk, having a ſhort ſpathe juſt below the flower, which covers it before it expands; that the tube of the flower is very ſhort, the petals being divided almoſt to the bottom, and terminating in acute points; that the ſtamens and ſtyle are ſhort, and the leaves very narrow; that the colour is deep blue, but that it varies of a ſky blue. 2. Autumnal mountain; which has a flower of a paler blue colour. 3. Many-flowering blueiſh; with many ſky-blue flowers. 4. Small-flowering. This has a ſmall flower of a deep blue colour.—[Parkinſon has the ſame number.—Ray has ſix.]

2. The Spring Crocus has a pretty large compreſſed bulb, covered with a light brown, netted ſkin, from which ariſe four or five leaves of a purpliſh colour on their lower parts: from among theſe come out one or two flowers, ſitting cloſe between the young leaves, never riſing above two inches high, and having an agreeable odour. Out of the centre of the tube ariſes a ſlender ſtyle, crowned by a broad flat ſtigma of a golden colour. After the flower is paſt the germ puſhes out of the ground.

[The Spring Crocus in its wild ſtate is moſt commonly white with a purple baſe in Switzerland, according to Haller. Purple or white in Auſtria, according to Jacquin. Geſner gathered it with a yellow flower on the mountains of Glarus. Scopoli does not mention its colour, but ſays that it is not uncommon in Carniola. It is a native alſo of Italy and Spain.—In Britain it is not indigenous. I remember, when a boy, to have ſeen it in conſiderable quantity, in Batterſea meadow near the mill, apparently wild. It has been found alſo in the meadows about Nottingham, by Dr. Deering.

The varieties of Spring Crocus are very numerous. Mr. Miller recites only twelve.]

1. Broad-leaved, purple, variegated. This has a flower of a deep blue, and ſtriped.
2. Broad-leaved, plain purple.
3. Broad-leaved, violet-coloured, or large deep blue.
4. White with a purple bottom.
5. Broad-leaved, white, variegated.
6. Broad-leaved, with many violet-purple flowers ſtriped with white.
7. Broad-leaved, aſh-coloured.
8. Broad-leaved large yellow.
9. Broad-leaved *ſmall* pale yellow.
10. Broad-leaved, ſmall yellow, ſtriped with black.
11. Narrow-leaved, *ſmall* brimſtone.
12. Narrow-leaved, *ſmall* white.

[Parkinſon has no leſs than twenty-ſeven, all of which he has named and deſcribed particularly.

Modern catalogues ſet down many varieties of the ſeveral colours, which are blue and purple, yellow and white, or ſtriped. New ones are alſo conſtantly imported from Holland, each of which has a french or dutch title. The moſt common varieties now in our gardens are the Scotch, beautifully ſtriped; the Blue; the Blue ſtriped; White; Yellow of ſeveral ſhades, larger and ſmaller; Yellow ſtriped with black; Cloth of gold.

I ſeparate the Vernal from the Autumnal Crocus, on the authority of Miller, Haller and Jacquin; and my own opinion formed before I had ſeen the works of the two latter.]

PROPAGATION AND CULTURE.

SPRING CROCUS.

If the ſeeds of theſe flowers were ſown, there might be a greater variety of them obtained than is at preſent; but as they propagate very faſt by offſets, the ſeeds are very rarely regarded.

All theſe ſeveral varieties of Crocuſes are very hardy, and will increaſe exceedingly by their roots, eſpecially if they are ſuffered to remain two or three years unremoved; they will grow in almoſt any ſoil or ſituation, and are very great ornaments to a garden early in the ſpring of the year, before many other flowers appear. They are commonly planted near the edges of borders on the ſides of walks; in doing which, you ſhould be careful to plant ſuch ſorts in the ſame line as flower at the ſame time, and are of an equal growth, otherwiſe the lines will ſeem imperfect. Theſe roots, loſing their fibres with their leaves, may then be taken up, and kept dry until the beginning of ſeptember, obſerving to keep them from vermin, for the mice are very fond of them. When you plant theſe roots, after having drawn a line upon the border, make holes with a dibble about two inches deep or more, according to the lightneſs of the ſoil, and two inches diſtance from each other, in which you muſt place the roots with the bud uppermoſt; then with a rake fill up the holes in ſuch a manner as that the upper part of the root may be covered an inch or more, being careful not to leave any of the holes open; for this will entice the mice to them, and when once they have found them out, they will deſtroy all your roots, if not prevented.

This is the way in which theſe flowers were commonly diſpoſed in gardens, but the better way is to plant them ſix or eight near each other in bunches between ſmall ſhrubs, or on the borders of the flower-garden; where, if the varieties of theſe flowers are planted in different patches, and properly intermixed, they will make a much better appearance than when they are diſpoſed in the old method of ſtraight edgings.

In january, if the weather is mild, the Crocus will often appear above ground; and in february their flowers will appear, before the green leaves are grown to any length, ſo that the flower ſeems at firſt to be naked; but ſoon after the flowers decay, the green leaves grow to be ſix or eight inches long, which ſhould not be cut off until they decay, notwithſtanding they appear a little unſightly; for by cutting off the leaves, the roots will be ſo weakened as not to arrive at half their uſual bigneſs, nor will their flowers the ſucceeding year be half ſo large. Their ſeeds are commonly ripe about the latter end of april, or the beginning of may, when the green leaves begin to decay.

AUTUMNAL CROCUS.

The autumnal Crocuſes are not ſo great increaſers as are thoſe of the ſpring, nor do they produce ſeeds in our climate, ſo that they are leſs common in the gardens; theſe muſt be taken up every third year, otherwiſe the roots will run long, and produce no flowers; but they ſhould not be kept out of the ground longer than the beginning of auguſt, for they commonly produce their flowers the beginning of *o*ctober; ſo that if they remain too long out of the ground, they will not produce their flowers ſo ſtrong, nor in ſuch plenty, as when they are planted early.

The method of cultivating Saffron, as it was preſented to the Royal Society, by Sir James Douglas.

1. *The choice and preparation of the ground.*—The greateſt part of the tract between Saffron Walden and Cambridge is an open level country, with few incloſures; and the cuſtom there is, to crop two years, and let the land be fallow the third. Saffron is generally planted upon fallow ground, and, all other things being alike, they prefer that which has borne Barley the year before.

The Saffron grounds are ſeldom above three acres, or leſs than one; and in chooſing, the principal thing they have to regard is, that they be well expoſed, the ſoil not poor, nor a very ſtiff clay, but

a temperate dry mould, ſuch as commonly lies upon chalk, and is of an Hazel colour; though if every thing elſe anſwers, the colour of the mould is pretty much neglected.

[Profeſſor Bradley aſſerts (Huſb. & Gard. 2. 125.) that he has ſeen it proſpering well in common heath ground, where the ſurface had been burnt; and that ſome gentlemen had, by his advice, planted ſome acres of it on ſuch ground, hardly worth one ſhilling an acre, with ſucceſs. He doubts not but their example will be followed by many who have ſuch ſort of land; there being no want of manure in this caſe but the aſhes. In the true ſpirit of a projector he remarks, that the firſt promoters of this eaſy part of huſbandry will be the greateſt gainers, becauſe as it becomes more general, the price of Saffron will aſſuredly fall: nay, he even queſtions not, but in a few years, we ſhall ſee rather too much than too little, and that the markets will become over-ſtocked. This prophecy, however, has not been fulfilled, nor have we heard any more of the heath-culture of Saffron.]

The ground being made choice of, about Lady-day, or the beginning of april, it muſt be carefully ploughed, the furrows being drawn much cloſer together, and deeper, if the ſoil will allow it, than is done for any kind of corn; and accordingly the charge is greater.

About five weeks after, during any time in the month of may, they lay between twenty and thirty loads of dung upon each acre, and having ſpread it with great care, they plough it in as before. The ſhorteſt rotten dung is the beſt; and the farmers, who have the conveniency of making it, ſpare no pains to make it good, being ſure of a proportionable price for it. About Midſummer they plough a third time, and between every ſixteen feet and an half, or pole in breadth, they leave a broad furrow or trench, which ſerves both as a boundary to the ſeveral parcels, when there are ſeveral proprietors to one incloſure, and to throw the weeds in at the proper ſeaſon.

To this head likewiſe belongs the fencing of the grounds, becauſe moſt commonly, though not always, that is done before they plant. The fences conſiſt of what they call dead hedges, or hurdles, to keep out not only cattle of all ſorts, but eſpecially hares, which would otherwiſe feed on the Saffron leaves during the winter.

About the weather we need only obſerve, that the hotteſt ſummers are certainly the beſt, and therewith, if there be gentle ſhowers from time to time, they can hardly miſs of a plentiful crop, if the extreme cold, ſnow, or rain of the foregoing winter have not prejudiced the heads.

2. *Planting or ſetting the roots.*—The only inſtrument uſed for this is a narrow ſpade, commonly termed a ſpit ſhovel.

The time of planting is commonly in the month of july, a little ſooner or later, according as the weather anſwers. The method is this: one man with his ſpit ſhovel raiſes between three and four inches of earth, and throws it before him about ſix or more inches; two perſons, generally women, following with heads, place them in the fartheſt edge of the trench he makes, at three inches diſtance from each other, or thereabouts; as ſoon as the digger or ſpitter has gone once the breadth of the ridge, he begins again at the other ſide, and digging as before, covers the roots laſt ſet, and makes the ſame room for the ſetters to place a new row, at the ſame diſtance from the firſt, that they are from one another. Thus they go on, till a whole ridge, containing commonly one rod, is planted; and the only nicety in digging is, to leave ſome part of the firſt ſtratum of earth untouched, to lie under the roots, and, in ſetting, to place the roots directly upon their bottom.

What ſort of roots are to be preferred ſhall be ſhewn under the fourth head, but it muſt be obſerved in this place, that formerly, when roots were very dear, they did not plant them ſo thick as they do now; and that they have always ſome regard to the ſize of the roots, placing the largeſt at a greater diſtance than the ſmall ones.

The quantity of roots planted in an acre, is generally about ſixteen quarters, or a hundred and twenty-eight buſhels, which, according to the diſtances left between them, as before aſſigned, and ſuppoſing all to be an inch in diameter one with another, ought to amount to three hundred and ninety-two thouſand and forty in number.

From the time that the roots are planted, till about the beginning of ſeptember, or ſometimes later, there is no more labour about them; but as they then begin to ſpire, and are ready to ſhew themſelves above ground (which is known by digging a few out of the earth), the ground muſt be carefully pared with a ſharp hoe, and the weeds, &c. raked into the furrows, otherwiſe they would hinder the growth of the plants.

3. *Gathering and drying the flowers.*—In ſome time after appear the Saffron flowers, and this leads us to the third branch of our preſent method. The flowers are gathered as well before as after they are full blown, and the moſt proper time for this is early in the morning. The owners of the Saffron get together a ſufficient number of hands, who place themſelves in different parts of the field, pull off the whole flowers, and throw them handful by handful into a baſket, and ſo continue till all the flowers are gathered, which happens commonly about ten or eleven o'clock.

Having then carried home all they have got, they immediately ſpread them upon a large table, and fall to picking out the ſtigmas, and together with them a pretty long proportion of the ſtyle itſelf; the reſt of the flower they throw away as uſeleſs. The next morning they return into the field again, whether it be wet or dry weather, and ſo on daily, even on Sundays, till the whole crop be gathered.

The ſtigmas being all picked out of the flowers, the next labour is to dry them on the kiln. The kiln is built upon a thick plank, that it may be moved from place to place, ſupported by four ſhort legs; the outſide conſiſts of eight pieces of wood about three inches thick, in form of a quadrangular frame, about twelve inches ſquare at the bottom on the inſide, and twenty-two inches at top, which is likewiſe equal to the perpendicular height of it. On the foreſide is left a hole about eight inches ſquare, and four inches above the plank, through which the fire is put in; over all the reſt laths are laid pretty thick, cloſe to one another, and nailed to the frame already mentioned, and then are plaiſtered over on both ſides, as are alſo the planks at bottom very thick, to ſerve for a hearth. Over the mouth, or wideſt part, goes a hair cloth, fixed to the ſides of the kiln, and likewiſe to two rollers, or moveable pieces of wood, which are turned by wedges or ſcrews, in order to ſtretch the cloth. Inſtead of the hair cloth, many people now uſe a net-work, or iron wire, with which it is obſerved that the Saffron dries ſooner, and with leſs quantity of fuel; but the difficulty in preſerving the Saffron from burning, makes the hair cloth be preferred by the niceſt judges in drying.

The kiln is placed in a light part of the houſe, and they begin by laying five or ſix ſheets of white paper on the hair cloth, upon which they ſpread the wet Saffron between two and three inches thick; this they cover with other ſheets of paper, and over theſe lay a coarſe blanket five or ſix times doubled, or, inſtead thereof, a canvas pillow filled with ſtraw; and after the fire has been lighted ſome time, the whole is covered with a board, having a large weight on it.

At firſt they give it a pretty ſtrong heat, to make the chives ſweat (as their expreſſion is;) and in this, if they do not uſe a great deal of care, they are in danger of ſcorching, and ſo of ſpoiling all that is on the kiln.

When it has been thus dried about an hour, they take off the board, blanket, and upper papers, and take the Saffron off from that which lies next it, raiſing

ufing at the fame time the edges of the cake with a knife; then laying on the paper again, they ſlide it another board between the hair cloth and upper papers, and turn both papers and Saffron upſide-down, afterwards covering them as above.

The ſame heat is continued for an hour longer; then they look on the cake again, free it from the papers, and turn it; then they cover it, and lay on the weight as before. If nothing happens amiſs during theſe firſt two hours, they reckon the danger to be over; for they have nothing more to do but to keep a gentle fire, and to turn their cakes every half hour till thoroughly dry, for the doing of which as it ought, there are required full twenty-four hours.

In drying the larger plump threads they uſe nothing more, but towards the latter end of the crop, when theſe come to be ſmaller, they ſprinkle the cake with a little ſmall beer, to make it ſweat as it ought; and they begin now to think that uſing two linen cloths next the cake, inſtead of the two innermoſt papers, may be of ſome advantage in drying, but this practice is followed but by few.

Their fire may be made of any kind of fuel, but that which ſmokes the leaſt is beſt, and charcoal, or that reaſon, is preferred to any other.

What quantity of Saffron a firſt crop will produce, is very uncertain; ſometimes five or ſix pounds of wet threads are got from one rood, ſometimes not above one or two, and ſometimes not enough to make it worth while to gather and dry it; but this is always to be obſerved, that about five pounds of wet Saffron go to make one pound of dry, for the firſt three weeks of the crop, and ſix pounds during the laſt week; and when the heads are planted very thick, two pounds of dried Saffron may, at a medium, be allowed to an acre for the firſt crop, and twenty-four pounds for the two remaining, the third being conſiderably larger than the ſecond.

In order to obtain theſe, there is only a repetition to be made every year of the labour of hoeing, gathering, picking, and drying, in the ſame manner as before ſet down, without the addition of any thing new, except that they let cattle into the fields, after the leaves are decayed, to feed upon the weeds, or, perhaps, mow them for the ſame uſe.

4. *Management of the roots.*—About the Midſummer after the third crop is gathered, the roots muſt be all taken up and tranſplanted. To take up the Saffron heads, or break up the ground (as the term is,) they ſometimes plough it, ſometimes uſe a forked kind of hoe, called a pattock, and then the ground is harrowed once or twice over; during all which time of ploughing, or digging, and harrowing, fifteen or more people will find work enough to follow and gather the heads as they are turned up.

They are next to be carried to the houſe in ſacks, and there cleaned and raſed; this labour conſiſts in cleaning the roots thoroughly from earth, and from the remains of old roots, old ſkins and excreſcences, and thus they become fit to be planted in new ground immediately, or to be kept for ſome time without danger of ſpoiling.

The quantity of roots taken up, in proportion to thoſe which were planted, is uncertain; but at a medium, it may be ſaid, that allowing for all the accidents which happened to them in the ground, and in breaking up from each acre, may be had twenty-four quarters of clean roots, all fit to be planted.

The owners are ſure to chooſe for their own uſe the largeſt, plumpeſt, and fatteſt roots, but do leaſt if all approve the longeſt pointed ones, which they all ſpickets, or ſpickards, for very ſmall, round, or lat roots, are ſometimes obſerved to flower well.

This is the whole culture of Saffron in the country above-mentioned, and we have only now to conſider the charges and profits which may be ſuppoſed, one year with another, to attend that branch of agriculture; and of theſe I have drawn up the following computation for one acre of ground, according to the price of labour in this country.

	l.	s.	d.
Rent for three years — —	3	0	0
Ploughing for three years —	0	18	0
Dunging — — —	3	12	0
Hedging — — —	1	16	0
Spitting and ſetting the heads —	1	12	0
Weeding or paring the ground	1	4	0
Gathering and picking the flowers	6	10	0
Drying the flowers — —	1	6	0
Inſtruments of labour for three years, with the kiln, about —	0	10	0
Ploughing the ground once, and harrowing twice —	0	12	0
Gathering the Saffron heads —	1	0	0
Raiſing the heads — —	1	12	0
Total charge	23	12	0

This calculation is made upon ſuppoſition, that an acre of ground yields twenty-ſix pounds of nett Saffron in three years, which I ſtated only as a mean quantity between the greateſt and the leaſt, and therefore the price of Saffron muſt be judged accordingly, which I think cannot be done better than by fixing it at thirty ſhillings per pound; ſince in very plentiful years it is ſold at twenty, and is ſometimes worth between three and four pounds; at this rate, twenty-ſix pounds of Saffron are worth thirty-nine pounds, and the nett profits of an acre of ground producing Saffron, will, in three years, amount to fifteen pounds, thirteen ſhillings, or about five pounds four ſhillings yearly.

This, I ſay, may be reckoned the nett profit of an acre of Saffron, ſuppoſing that all the labour were to be hired for ready money; but as the planter and family do a conſiderable part of the work themſelves, ſome of this expence is ſaved; that is, by planting Saffron, he may not only reaſonably expect to clear about five pounds yearly per acre, but alſo to maintain himſelf and family for ſome part of each year; and it is upon this ſuppoſition only, that the reſult of other computations can be ſaid to have any tolerable degree of exactneſs, but the calculations themſelves are undoubtedly very inaccurate.

I have ſaid nothing here concerning the charge in buying, or profits in ſelling, the Saffron heads, becauſe, in many large tracts of ground, theſe muſt at length balance one another, while the quantity of ground planted yearly continues the ſame, which has been pretty much the caſe for ſeveral years paſt.

CROCUS. See *Hypoxis*, *Ixia*, *Memecylon*.

Leaves ternate wedge-form; branches pubeſcent, legumes pedicelled ſmooth wrinkled compreſſed keeled.

25. Crotalaria axillaris. *Two-flowered Crotalaria.* *Ait. hort. kew.* 3. 20.
Leaves ternate ovate-elliptic hairy beneath; ſtipules ſubulate minute; peduncles axillary twin one-flowered.

26. Crotalaria pallida. *Pale-flowered Crotalaria.* *Ait. hort. kew.* 3. 20.
Leaves ternate lanceolate ſmooth; racemes terminating ſpike-form.

* *Leaves ſimple.*

27. Crotalaria ſericea. *Silky-leaved Crotalaria.* *Retz. obſ.* 5. *n.* 69.
Leaves lanceolate acute ſilky beneath; racemes elongated.
Mr. Miller has three other ſpecies.

28. Crotalaria fruticoſa.
Mill. dict. n. 4. *Houſt. Mſs.*
Leaves ſimple linear-lanceolate hirſute, petioles decurrent; ſtem ſhrubby.

29. Crotalaria villoſa.
Mill. dict. n. 8. *Lin. hort. cliff.* 357. *Herm. lugdb.* 170.
Leaves ſimple ovate villoſe; petioles entirely ſimple; branches round.

30. Crotalaria angulata.
Mill. dict. n. 9.
Leaves ovate ſeſſile; branchlets angular hirſute; flowers lateral very ſimple.
From Loureiro.

31. Crotalaria heptaphylla. *Seven-leaved Crotalaria.* *Lour. cochinch.* 433.
Leaves pinnate with ſeven leaflets, ſpikes long, ſtem arboreous.

32. Crotalaria ſcandens. *Climbing Crotalaria.* *Lour. cochinch.* 433.
Leaves oblong, peduncles many-flowered axillary, ſtem ſhrubby climbing.

DESCRIPTIONS, *&c.*

The plants of this genus are either herbs or ſhrubs; the leaves either ſimple, ternate, or in ſome few caſes digitate; ſtipules either ſcarcely any, or conſpicuous, and for the moſt part diſtinct from the petiole; flowers generally in ſpikes, in ſome ſpecies terminating, in others axillary, or elſe oppoſite to the leaves; the legume in moſt is ſhort, with only one or two ſeeds in it, but in ſome it is longer, and contains ſeveral ſeeds. The genus ought certainly to be reformed, and ſome of the ſpecies referred to other genera[a].

Dillenius diſtinguiſhes it from Anonis or Ononis, by the greater length and more ſwelling form of the legumes; he obſerves alſo that they are pendulous in this genus: that the plant has no ſpines; that the leaves are not ſerrate, and the petioles not leafy.

1. Height eight feet. Stem ſmooth and even, with alternate branches. Leaves ſmooth, veined, ſcarcely an inch in length. The flowers ſmooth, yellow, in a kind of umbel, two together, terminating the branches. Standard hoary, pubeſcent on the outſide. Legumes compreſſed, ſmooth, not pedicelled, acute.

Native of the Cape of Good Hope[b]; where a decoction of the leaves is eſteemed a powerful diuretic.]

2. Stem ſhrubby, four or five feet high, round, covered with a light-brown bark. Leaves ſmooth, about four inches long, and near three broad, [reſembling much thoſe of our common *Thorough-wax* (Bupleurum) both in ſize and ſhape, but they are ſtiffer and more veined. The flowers are almoſt as large as thoſe of the Pea, all the petals being large.] They are of a pale yellow colour, and come out

[a] Lamarck. [b] Linn. mant. & amoen.

ſingly from the upper part of the branches, ſitting cloſe in the axils of the leaves; and appear in auguſt. [Legume ſmooth, cartilaginous, browniſh. It has the appearance of being ſhrubby, but the branches periſh every year. Its height is two feet, and it grows in open woods two hundred miles to the back of the ſettlements in Carolina. It was cultivated, but did not flower, in the Eltham garden, about the year 1732[c].] Mr. Miller had it from Dr. Dale, probably at the ſame time; it flowered with him, but did not produce any pods.

[3. This is a ſmooth ſhrub. Leaves ſmooth. Flowering branches dichotomous; the flowers yellow, peduncled, from the diviſions.

Native of the Cape of Good Hope[d].

4. Root annual. Stem herbaceous, half a foot high and more, erect, ſubdivided, ſtrict, round, pubeſcent. Leaves on very ſhort petioles, alternate, entire, rounded at the baſe, hoary underneath, and ſomewhat hirſute; (but ſometimes ſmooth.) Stipules at the ſides of the petioles, decurrent, bifid at the top, acute, as it were ſagittate. Peduncles terminating, ſolitary, oppoſite to the petioles, ſtrict, round, two or three-flowered. Flowers yellow, pedicelled. Calyx five-parted; two ſegments poſterior, three anterior, ovate-lanceolate, hirſute: at the baſe are two or three leaflets. Standard of the corolla roundiſh, erect, ſpreading, pale: wings ovate, embracing the keel; which is bifid at the baſe, and blunt at the end. Five of the filaments ſhorter than the other five: anthers oblong, thoſe of the ſhorter filaments ſmaller, roundiſh. Legume ſubſeſſile, almoſt cylindric, veined, pellucid, when ripe blackiſh. Seeds pedicelled, fixed to the future in a quadruple row, kidney-form, ſhining[e].

Native of South America and Jamaica. It was firſt raiſed here in the botanic garden at Cheſſea, from ſeeds ſent by Mr. Robert Millar, Surgeon, from Porto Bello, in the year 1734[f].]

Miller makes two ſpecies of this, 1. C. piloſa, n. 2. the ſeeds of which were ſent from La Vera Cruz by Dr. Houſtoun. 2. C. ſagittalis, n. 3: which Dr. Dale ſent him from South Carolina; and Dr. Houſtoun from Jamaica; ſo that it grows naturally in ſeveral parts of America. The latter is a lower plant, and the flowers are not more than half the ſize of the others.

[5. Shrubby. Stems and branches pubeſcent, round. Leaves blunt iſh, very entire, ſomewhat hairy on both ſides. Racemes few-flowered, rough with hairs. Bractes lanceolate, the length of the peduncles. Calyxes rough with hairs, the length of the corolla; which is yellow, with a ſtriated banner. Stipules ſubulate. Native of China[g].]

6. This riſes with an angular, ruſhy, ſtiff ſtem, from three to near four feet in height, dividing into three or four branches. Leaves narrow-lanceolate, alternate, cloſely covered with ſoft ſilvery hairs, on very ſhort petioles. The flowers are produced at the ends of the branches, in looſe ſpikes. [Upper lip of the calyx two-parted; lower boat-form, obſcurely three-toothed. Corolla large, deep yellow, with the axils of the wings black, having the appearance of Spaniſh Broom, (Spartium junceum.)[h]] The ſtyle ſtands out beyond the ſtandard. The flowers are ſucceeded by large turgid pods, containing one row of large kidney-ſhaped ſeeds.

Native of the Eaſt-Indies. The ſeeds were brought to Mr. Miller from the coaſt of Malabar before 1768, and ſucceeded in the Cheſſea garden.

[7. This is a ſhrub, warted with knots from the fallen leaves: theſe are crowded, ſubimbricate, ſilky, ſmall, without ſtipules. Flowers ſolitary, purple. Native of the Cape of Good Hope[i].]

8. This riſes with an herbaceous ſtem near three feet high, dividing into ſeveral branches. Leaves pale green and ſmooth, ſobovate with a recurved point, whence they are retuſe. Stipules very ſmall,

[c] Dillenius. [d] Linn. amoen. [e] Swartz.
[f] Mart. cent. [g] Linn. ſpec. [h] Ibid.
[i] Linn. amoen.

ſubulate, ſtanding out.] The flowers are produced in ſpikes at the end of the branches; they are pretty large, and of a yellow colour, [with the banner often purpliſh above. Legume ſmooth, cylindric, horizontal [k]; widening upwards, inflated, turgid at the ſides, depreſſed along the ſeed-bearing ſuture, and towards the baſe gradually attenuated into the peduncle. Seeds from fifteen to twenty, three-cornered-reniform, ending in a hooked beak remote from the ſeed, ſmooth, ſhining, dark-cheſtnut colour [l].

Native of the Eaſt-Indies. Annual. Cultivated by Miller in 1731 [m].] He received the ſeeds from Boerhaave. It flowers in july; and the ſeeds ripen in autumn, provided the plants are brought forward in the ſpring.

[9. Annual. Scarcely a foot high. Stem erect, round, little branched, ſtriate-furrowed. Leaves ſmooth on their upper ſurface, hairy on their lower. Stipules hardly viſible. Flowers axillary, blue; with two oblong bractes.—Native of China [n].

10. The whole plant is ſmooth. Leaves almoſt three inches in length. Bractes from the axils of the leaves towards the top, in threes, a little ſmaller than the leaves, and the length of the flowers.—Native of the Cape [o]. Biennial: flowering in june. Introduced 1786, by Mr. Francis Maſſon [p].]

11. *This* is an annual plant. Stem herbaceous, four-cornered, two feet high, [erect, flexuoſe]; dividing into three or four branches at top, which have alſo four acute angles. Leaves warted, pale green, on very ſhort petioles. [Racemes terminating: flowers alternate, ſmooth [q],] of a light blue colour; ſucceeded by ſhort turgid pods, incloſing one row of kidney-ſhaped ſeeds. It flowers in july and auguſt, and the ſeeds ripen in autumn. Native of the Eaſt-Indies. [Cultivated 1731, by Mr. Miller [r].

12. Stem erect, a palm in height, round, hairy, terminated by the peduncle. Branches from the baſe of the ſtem, many, alternate, ſimple, much longer than the erect ſtem. Leaves alternate, on very ſhort petioles, elliptic or oval-oblong, without veins, a little hairy, an inch in length. Peduncles terminating; but on the branches, the branch extending itſelf beyond the flower, they become lateral. Corolla yellow; the banner ovate, aſcending, the length of the calyx; (which is divided into five parts, the upper part biſid) wings oblong, preſſed cloſe; keel ventricoſe, beaked. Filaments alternately longer and ſhorter; anthers oblongiſh, but on the barren filaments round. Germ ovate, with a villoſe ſtigma. Legume twin-globular (becoming by culture ſubcylindric) inflated, one-celled, containing ſeveral ſeeds, on ſtiff, briſtle-form pedicels. There is no diſtinct ſtamen in the flower.—In the garden it puts on an appearance very different from what it has in its native ſoil, in the Eaſt-Indies. Koenig found it in the iſland of St. Johanna [s].

13. Shrubby, ſtems ſimple, very ſmooth. Leaves obtuſe, erect. Peduncles on the top of the ſtem, elongated, with a pair of leaves towards the flower, like thoſe of the ſtem. The flower comes out between the leaves of the peduncle, is ſingle, nodding and yellow. Found by Thunberg at the Cape of Good Hope [t].

14. Stems erect, filiform, ruſhy, ſimple, hirſute, hoary. Leaves on very ſhort petioles, and ſhorter. Racemes long. Flowers nodding, yellow. Legumes ſhort, obtuſe. It is like enough to *C. juncea* n. 6. Obſerved by Koenig, in the Eaſt Indies [u].

15. Stems diffuſed, round, pubeſcent. Leaves on ſhort petioles, ſpreading very much. Stipules ovate, tubular, reflex. Peduncles terminating, erect, long, filiform. Bractes two, near the flower, on the peduncle, oppoſite, like ſtipules. Corollas blueiſh, of the larger ſize. Legumes oblong with an acumen, hiſpid.—It varies in the form of the leaves. Found by Koenig, in the queen of Tanjour's garden, Amma Koil [x].

16. Stems ſarmentoſe, ſlender and weak, at bottom ſtiff and woody, but higher up, herbaceous, round, from a foot to eighteen inches in height, and more; about the middle dividing into branches, which are not very frequent, on which at ſhort intervals grow ſmooth ternate leaves, with a pair of ſtipules at the baſe of each petiole. Flowers axillary, on peduncles ſhorter than in ſome other ſpecies, three or four together, yellow, reſembling thoſe of the common Lotus; the banner larger than the other petals, and reflex, but the edges inflex, marked with ſo many red lines on the hinder part, as to appear wholly red there; wings and keel unſpotted, the latter greeniſh yellow; the wings converge and cover the keel. Legumes from one to three, ſubhirſute, ſwelling, rattling when the ſeeds are ripe.—The ſeeds came either from the Havanna or Mexico [y]. It is a native of Jamaica. Flowers in june and july; and was cultivated in the Eltham garden, 1732 [z].

17. Native of the Cape of Good Hope.]

18. Stem ſhrubby, four or five feet high, dividing into many branches. Flowers large, yellow, in large bunches from the ſide of the branches, appearing from july to ſeptember, and making a fine appearance.

[Annual. Plant ſmooth. Legume in the calyx peduncled. Keel of the corolla broad, compreſſed, beaked; wings half the length of that and the banner [a].

19. A ſhrub, eight feet in height, branched: branches ſomewhat angular, with truncated ſcars. Leaves petioled; leaflets ſmooth, ſharp at the baſe, nearly equal. Petioles ſhorter than the leaves. Stipules briſtle-form, minute. *Corymbs* terminating, ſolitary, ovate: peduncles, calyxes and corollas violet-coloured. The flower reſembles that of *Sophora biflora*. Stamens connate. Native of the Cape, on rocks [b].

20. Root annual. Stem from two to four feet high, almoſt ſimple, erect, pubeſcent. Leaves elliptic, entire, nerved. General petioles long, angular, horizontal, pubeſcent; partial very ſhort, round. Stipules ſolitary, deciduous. Flowers ſubracemoſe, greeniſh yellow, rather large. Peduncles three or four-flowered, ſhort, axillary. Pedicels longer than the peduncles. Bractes two, ſubulate (ſetaceous. Lin.) under each flower. Calyx five-cleft, ſilky. Standard of the corolla fulvous, ſtreaked; the reſt yellow. Stigma acute. Legume ſubſeſſile, turgid-inflated, villoſe-pubeſcent, beaked with the permanent ſtyle. Seeds oblong. It has the common ſmell of the leguminoſe tribe, but is fetid [c].

Native of the Weſt-Indies. It flowers in june and july. Cultivated 1714, by the Dutcheſs of Beaufort [d].

21. A ſhrub with hoary branches, very finely white-tomentoſe, in which it differs evidently from *C. laburnifolia*, which is ſmooth. Leaves petioled, naked; leaflets oval, nearly equal; petioles hoary. Stipules two, at the origin of each petiole, exactly reſembling the leaves, only of half the length. Panicles ſmall, ſimple. Flowers yellow: wings ſhorter than the keel, which is lunate, and ſomewhat beaked. —It ſeems to be only a variety of *C. laburnifolia*, for the ſtipules drop, after it has flowered [e].

Native of the Cape of Good Hope; flowering from june to october. Introduced 1774, by Mr. Francis Maſſon [f].

22. Annual. Stem erect, a foot high, ſmooth, a little branched at top. Lower ſtem-leaves elliptic, oleraceous, ſmooth, ribbed with nerves: upper obovate, alike. Petioles very ſhort, channelled. Stipules ſmall, ſubulate, patulous. Raceme when flowering terminating, when fruiting lateral. Corollas yellow, ſomewhat teſtaceous on the outſide,

striate-

ſtriate-nerved. Legumes ſmooth. Native of the Eaſt-Indies [e].

23. Leaflets narrow-lanceolate, obtuſe, often retuſe, almoſt naked, the ſide ones ſhorter. Calyxes bell-ſhaped. Flowers in racemes, alternate, ſmooth. Native of the Eaſt-Indies [b].

24. Native of the Cape of Good Hope. Found there by Mr. William Paterſon. It is ſhrubby, and flowers in july and auguſt. Introduced 1780, by the Counteſs of Strathmore.

25. Native of Guinea. Found there by Mr. William Braſs. It is annual, and flowers in july. Introduced 1781, by the Earl of Tankerville and Dr. Pitcairn.

26. Native of Africa. Found there by James Bruce, Eſq. It is annual, and flowers in june and july. Introduced 1775 [i].

27. A loſty plant, appearing to be ſhrubby, but in reality annual. Stem branched, ſtriated. Leaves on ſhort petioles, oblong, lanceolate, with a minute point, decreaſing towards the petiole, the upper ſurface ſmooth. Stipules ſemicordate, acuminate. Racemes ſimple, terminating and axillary. Bracteas cordate, acuminate. Flowers peduncled, ſolitary, yellow. Peduncles having two or three ſmall bracteas in the middle. Upper lip of the calyx deeply bifid; lower three-toothed, with the teeth lanceolate. Style thickening towards the ſtigma, hairy. Communicated by Koenig [k].]

28. The twenty-eighth ſort grows naturally in Jamaica, whence the ſeeds were ſent me by the late Dr. Houſtoun; this riſes with a ſhrubby taper ſtalk near four feet high, ſending out many ſide branches, which are very ſlender, ligneous, and covered with a light brown bark; the younger ſhoots have a leafy border or wing on two ſides, but the old branches have none; the flowers are produced near the end of the branches, three or four growing alternate on a looſe ſpike; they are of a dirty yellow, and ſmall; the pods which ſucceed them are about an inch long, very turgid, and of a dark blue when ripe.

29. The twenty-ninth ſort grows naturally at the Cape of Good Hope, whence I received the ſeeds. This riſes with a ſhrubby ſtalk about five feet high, dividing into ſeveral branches, with roundiſh leaves, ſitting cloſe to the branches; they are of a hoary green, and ſoft to the touch, the branches are taper and ſmooth; the flowers are produced at the end of the branches in looſe ſpikes; they are about the ſize of thoſe of the eleventh ſort, and of a fine blue colour. They come out in june and july, and in warm ſeaſons the ſeeds ripen in autumn.

30. This is an annual plant, riſing with a taper upright ſtem near three feet high, dividing at top into ſeveral hairy upright branches. Leaves ovate-lanceolate, pale green. The flowers are produced ſingly from the ſide of the branches, are of a bright yellow, and are ſucceeded by ſhort turgid pods, having one row of kidney-ſhaped ſeeds. It flowers in july and auguſt, and will perfect ſeeds in autumn. It was ſent from Campeachy, where it grows naturally.

[31. This is a tree ten feet in height, with diffuſed branches. Leaves unequally pinnate; leaflets ovate-oblong, veined, ſubtomentoſe; petioles ſhort. Flowers white, axillary and terminating, in long ſimple ſolitary ſpikes. Calyx five-toothed, villoſe, ſhort. Standard of the corolla emarginate, riſing; wings oblong, half the length of the ſtandard: keel bent in, ſhorter than the wings. Legume pedicelled, turgid, villoſe, unequal. Seeds few, roundiſh.

32. This is a large ſhrub, with long, woody, ſcandent branches. Leaves ovate-oblong, acuminate, quite entire, ſmooth, alternate, petioled. Flowers white. Calyxes ſmooth. Petals nearly equal, ſpreading. Legume turgid, acuminate at both ends; containing few ſeeds. This and the preceding are natives of Cochinchina [l].]

[e] Linn. ſuppl. [b] Linn. ſpec. [i] Hort. kew. [k] Retz. [l] Loureiro.

PROPAGATION AND CULTURE.

Moſt of theſe plants are propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring, and when the plants are come up an inch high, they ſhould be tranſplanted to another hot-bed to bring them forward, obſerving to ſhade them from the ſun till they have taken new root; after which they ſhould have free air admitted to them in proportion to the warmth of the ſeaſon, to prevent their being drawn up weak. When the plants have acquired ſtrength in this bed, they ſhould be carefully taken up, with balls of earth to their roots, and each planted in a ſeparate pot, filled with light kitchen-garden earth, and plunged into a moderate hot-bed of tanner's bark, carefully ſhading them till they are rooted again; then they muſt be treated in the ſame manner as other tender exotic plants, giving them proper air and water in warm weather; when the plants are grown ſo tall as to nearly reach the glaſſes of the hot-bed, the pots may be removed into an airy glaſs caſe, or ſtove, where they may be ſcreened from inclement weather, and have proper air in hot weather; with this treatment the plants will flower in july, and continue to produce freſh ſpikes of flowers till the end of auguſt; and thoſe ſpikes of flowers which appear early in the ſeaſon, will be ſucceeded by ripe ſeeds in ſeptember, ſoon after which the plants will decay.

6. This plant is annual in England, but by the lower part of the ſtalk growing woody, it appears to be of longer duration in the country where it naturally grows; though it will not live through the winter here, for if the plants are placed in a ſtove, the heat is too great for them, and in a green-houſe they are very ſubject to mouldineſs in damp weather. I have ſown the ſeeds of this in the full ground, where the plants have grown upward of three feet high, and have flowered very well, but no pods were formed on theſe; and when they have been treated tenderly, the plants have grown much larger, and produced a greater number of flowers, but theſe have produced no ſeeds. The only way which I could obtain any ſeeds, was by raiſing the plants in pots upon hot-beds; and the beginning of july turning them out of the pots into the full ground on a very warm border under a wall, in which ſituation they flowered very well, and ſome few pods of ſeeds were ripened.

18. It is eaſily propagated by cuttings, during the ſummer months, if the cuttings are planted in pots, and plunged into a moderate hot-bed, being careful to ſhade them till they have taken root, and frequently refreſh them with water: during the months of july, auguſt, and ſeptember, the plants may be expoſed to the open air in a ſheltered ſituation, where they will produce many flowers; but in the autumn they ſhould be placed in a temperate ſtove, to preſerve them in winter.

[Thoſe ſpecies which are natives of the Cape will be ſufficiently protected by the Conſervatory or dry Stove; but ſuch as come from the Eaſt-Indies, and the hotter parts of Africa, muſt be kept in the Bark Stove.]

CROTALARIA. See *Glycine* and *Sophora*.

CROTON. (Κροτων *of Dioſcorides. Derivation unknown.*)

Lin. gen. n. 1083. *Reich.* 1181. *Schreb.* 1462. *Gærtn. t.* 107. *Ricinoides Tourn.* 423.

Claſſ. 21. 9. Monoecia Monadelphia.—Monadelphia Dodecandria. *Thunb.*

Nat. order of *Tricoccæ.—Euphorbiæ.* Juſſ. 389.

GENERIC CHARACTER.

* *Male flowers* ſmaller than the females.

CAL. *Perianth* cylindric, five-toothed.

COR. *Petals* in ſome five, ſcarce larger than the calyx, oblong, obtuſe.

Nectary five glands, affixed to the receptacle, ſmall.

STAM. *Filaments* ten or fifteen, ſubulate, connected at the baſe, length of the flower. *Anthers* roundiſh, twin.

* *Female flowers* remote from the males, on the ſame plant.

CAL.

CAL. *Perianth* many-leaved: *leaflets* ovate-oblong, erect.
COR. *Petals* as in the males (in some scarce manifeſt.)
PIST. *Germ* roundiſh. *Styles* three, reflex-ſpreading, length of the flower, half-two-cleft. *Stigmas* reflex, two-cleft.
PER. *Capſule* roundiſh, three-lobed at the ſides, three-celled, each of the cells two-valved, ſize of the calyx; frequently much larger.
SEED ſolitary, ovate, large.
OBS. *This genus is allied to* Acalypha, *differing chiefly in the calyx. Some ſpecies are furniſhed with petals, others are apetalous. Several have the filaments detached.*
In Cr. tinctorium *the calyx is five-leaved: the petals five, lanceolate. Stamens eight, monadelphous.*
In Cr. lucidum: *the calyx in the male flowers is ten-leaved; corolla none; filament twelve: In the female flowers calyx five-leaved; germ beſtute; ſtyles three, ſix-parted.* R.
Species 42 *is dioecous: ſpecies* 51, *polygamous.*

ESSENTIAL CHARACTER.

MALE. *Cal.* cylindric, five-toothed. *Cor.* five-petalled. *Stam.* ten to fifteen.
FEM. *Cal.* many-leaved. *Cor.* none. *Styles* three, bifid. *Capſ.* three-celled. *Seed* one.

Leaves ovate very entire, ſtem arboreous.

28. Croton hirtum.
L'Herit. ſtirp. nov. faſc. 1. 17.
Leaves ovate ſerrate, with glanduliferous hairs at the baſe, ſpikes ſeſſile, ſtem hiſpid.]

29. Croton althæifolium.
Mill. dict. n. 9.
Ricinoides americana fruteſcens, althææ fol. *Plum. cat.* 20.
Leaves oblong-cordate tomentoſe, ſtem ſhrubby branched, flowers in terminating ſpikes.

30. Croton ſalviæfolium.
Mill. dict. n. 10.
Ricinus ſalviæ fol. utrinque molli. *Pet. hort. ſicc.*
Leaves cordate acute, tomentoſe beneath, ſtem ſhrubby, flowers in ſpikes terminating and axillary.

31. Croton ſeſſiliflorum.
Swartz. prodr. 100.
Leaves ovate acuminate quite entire ſmooth, flowers ſeſſile axillary dioecous five-ſtamened.

32. Croton globoſum.
Swartz. prodr. 100.
Leaves ovate obtuſe entire, peduncles in pairs, flowers dioecous, fruits globular, echinate-hiſpid.

33. Croton divaricatum.
Swartz. prodr. 100.
Leaves oblong obtuſe ſerrate, rough with hairs, biglandular at the baſe, racemes terminating ſolitary, ſtem ſhrubby, branches dichotomous divaricate.

34. Croton nitens.
Swartz. prodr. 100.
Leaves cordate-elliptic acuminate almoſt entire ſmooth ſhining above, dotted and ſilvery underneath, racemes axillary, branches ſhorter, erect.

35. Croton laurinum.
Swartz. prodr. 100.
Leaves oblong ovate quite entire, of ſome conſiſtence, ſmooth, petioles rugged, they and the leaves dotted underneath, racemes axillary, very long, patulous, ſtem arboreſcent.

36. Croton pallens.
Swartz. obſ. 102.]
C. fruticoſum. *Mill. dict. n.* 6.
Ricinoides fruteſcens, lauri fol., calyce ampliſſimo viridi. *Houſt. Mſs.*
Leaves ovate acuminate quite entire, ſmooth on both ſides, racemes ſolitary erect terminating, calyxes larger than the fruit.

37. Croton macrophyllum.
Swartz. prodr. 100.
Leaves cordate-roundiſh acuminate entire thick tomentoſe, nerved underneath.

38. Crotum populifolium.
Swartz. prodr. 101. *Vahl ſymb.* 2. 97.
Leaves broad-ovate acuminate ſerrate-toothed, ſomewhat rough with hairs, with one gland at the baſe above, petioles the length of the leaves, racemes terminating erect ſolitary, ſtem ſhrubby.

39. Croton cochinchinenſe.
C. punctatum. *Lour. cochinch.* 581.
Leaves lanceolate quite entire hoary underneath, ſhining, dotted, capſules ſcurfy.

40. Croton lanatum.
Lour. cochinch. 581.
Leaves ovate-lanceolate quite entire ſmooth oppoſite, corollas woolly, capſules ſix-valved.

41. Croton congeſtum.
Lour. cochinch. 582.
Leaves ovate gaſh-ſerrate ſmooth veined, flowers heaped naked axillary.

42. Croton dioicum.
Cavan. ic. hiſp. 2. *n.* 6. *t.* 6.
Leaves oblong obtuſe hoary, flowers terminating, on the male in ſpikes, on the female by threes.

43. Croton plicatum.
Vahl ſymb. 1. 78.
Leaves ovate plaited crenate hinſute, ſtem herbaceous.

44. Croton obliquum.
Vahl ſymb. 1. 78.
C. argenteum. *Forſk. ægypt.* 75. *n.* 191?
Leaves ovate-lanceolate quite entire, ſtem herbaceous, tomentoſe.

45. Croton coccineum.
Vahl ſymb. 2. 97.
Leaves ovate acuminate quite entire ſmooth, biglandular at the baſe, dotted with ſcarlet underneath, racemes terminating.

46. Croton lævigatum.
Vahl ſymb. 2. 97.
Leaves elliptic, very ſmooth and even, without glands, entire and ſerrate, obtuſe, racemes terminating, elongated.

47. Croton betulinum.
Vahl ſymb. 2. 98.
Leaves ovate obtuſe crenate-toothed, rugged, with dots on the upper ſurface, ſomewhat rough, with hairs underneath, racemes axillary.

48. Croton goſſypifolium.
Vahl ſymb. 2. 98. *t.* 49.
Leaves cordate three-lobed tomentoſe, biglandular at the baſe underneath, ſtem arboreous.

49. Croton procumbens.
Jacqu. amer.
Leaves wedge-ſhaped acute quite entire.

50. Croton nivcum.
Jacqu. amer. pict. t. 263. *f.* 59.
Leaves cordate acuminate ſerrulate, tomentoſe-ſhining beneath, ſtem ſhrubby.

51. Croton polygamum.
Jacqu. amer. pict. t. 243.
Leaves lanceolate ſerrate, thinly ſet with decumbent hairs.

52. Croton? cyanoſpermum.
Gærtn. fruct. 2. 120.

53. Croton cardioſpermum.
Gærtn. fruct. 2. 120.

DESCRIPTIONS, *&c.*

The plants of this numerous genus are herbaceous, or more frequently ſhrubby. Leaves accompanied with ſtipules, generally alternate, ſeldom oppoſite. Flowers axillary or terminating, uſually in ſpikes, but ſometimes in corymbs: the ſpikes are moſtly monoecous (ſometimes dioecous, n. 2. or polygamous, n. 51.); the males above, the females below*. They are chiefly inhabitants of the Eaſt or Weſt-Indies: the ſixth ſpecies alone is European.

1. Native of Amboina and Japan: alſo of Malicollo and Tanna in the South Seas.]

2. This riſes with a ſhrubby ſtem about ſix or ſeven feet high, ſending out many ſide branches, which are covered with a ſmooth bark of a yellowiſh

* Jaſſieu.

white colour, and garniſhed very cloſely with narrow ſtiff leaves, near three inches long, and about one eighth of an inch broad, of a light green on their upper ſide, but their under of the ſame colour with the bark, the midrib is furrowed on their upper ſide, and very prominent on the lower: the upper part of the branches divide into four or five ſmaller, ariſing from the ſame joint, and nearly equal in length; between theſe ariſes a long looſe ſpike of whitiſh green flowers. The whole plant has an aromatic odour when rubbed.

[According to Jacquin, it is only four feet high, and upright, the branches round, the leaves on a ſhort petiole, furniſhed with two ſtiffiſh ſtipules. Swartz remarks, that on the coaſt it has narrower leaves, and broader ones more in land; and that the flowers are dioecous.

It reſembles the European Roſemary pretty much, both in the manner of its growth, and the form and colour of its leaves, whence it has acquired the name of *Wild Roſemary*, in Jamaica. It is frequent on the ſouth ſide of the iſland, and generally uſed in warm reſolutive baths and fomentations[a]. Native of Jamaica, and other parts of the Weſt-Indies. It flowers in july, and was introduced about 1772 by Mr. William Malcolm[b].] It had, however, been cultivated before by Mr. Miller, to whom the ſeeds were ſent from Jamaica by Dr. Houſtoun.

[3. Native of South America[c].

4. Root annual. Stems round, ſungous, ſmooth, procumbent or erect. Leaves oblong, ſerrate, ſmooth on both ſides, uſually two inches long, ſeldom one broad; petioles half an inch in length. Flowers axillary, towards the top of the ſtem, on ſpikes two inches long, in the upper part of which are four or five males, in the lower three or four females. The fruit is the ſize of a pea, rough with warts, or ſoft little ſpines. It varies in the ſize and form of the leaves.

Cultivated in the botanic garden at Chelſea in 1731[d]. Martyn has given an outline of the wild plant, by the ſide of that which was raiſed in the garden; and they differ ſo widely, that it would be difficult to ſuppoſe them of the ſame ſpecies, did we not know what great changes ſoil and climate will operate.]

Mr. Miller ſays, that the plant in its native marſhes has broad flat ſtalks, and leaves three inches long, ſcarce a quarter of an inch broad, rough, and but little indented on the edge; but that in dry ground the leaves are ovate, upwards of two inches broad, and ſerrate. He had the ſeeds from Dr. Houſtoun, who diſcovered it near La Vera Cruz. It flowers in july, and the ſeeds ripen in autumn.

[5. This grows in a ſhrubby form, and is ſeldom under ſeven or eight feet in height. All the parts of the plant are of an active warm nature, and have a pretty agreeable ſmell. It is common in all the low lands about Spaniſh town and Kingſton in Jamaica[e]: and was introduced here in 1778, by Thomas Clarke, M. D.[f]]

6. Root annual. Stem herbaceous, branching, about nine inches high. Leaves near two inches long, and one inch and a quarter broad in their wideſt part, on ſlender petioles near four inches long. Flowers in ſhort ſpikes from the ſide of the ſtalks, at the ends of the branches. [Stems covered with a glaucous meal. Leaves rhomboid, toothed, ſubtomentoſe. The male flowers diſpoſed in racemes. Calyx five-parted (five-leaved. *Lin.*) Petals five, lanceolate. Stamens eight or nine, monadelphous. Female flowers below the males, axillary, pedunculed. Capſules tricoccous, ſcabrous, nodding. See *n.* 47.

The women about Albudebar dye their ſtockings with it.

Niſſole dyed both ſilk and wool of an elegant blue colour. But the attempts in France to produce a material from it for dyeing ſimilar to Indigo, did not meet with ſucceſs[g].]

This is the plant from which the Tournſol is made, that is uſed for colouring wines and jellies. It is made of the juice which is lodged between the calyx and the ſeeds: this, if rubbed on cloths, at firſt appears of a lively green, but ſoon changes to a blueiſh purple; if theſe cloths are put into water, and afterwards wrung, they will dye the water of a claret colour; the rags thus dyed, are brought to England, and ſold in the druggiſts ſhops by the name of Tournſol.

[Native of the South of France, Spain and Italy; and the kingdom of Tunis.

Cultivated 1570[h]. It flowers in july.

7. This ſeldom riſes above ſixteen or ſeventeen inches in height. The ſeeds are ſmall, and picked up every where in the fields, both by the wild and tame fowls, in the iſland of Jamaica, of which it is a native, in the Savannahs of Liguanea[i].]

8. Root annual. Stem a foot high, angular; branches naked from their diviſion to the top. Leaves an inch and half long, and three quarters of an inch broad, on petioles an inch in length. Flowers in ſhort cloſe terminating ſpikes, the upper ones male, the lower female, all white, the former ſoon falling.

[The head of fruits has three oval, hirſute, toothed bractes[k].

Introduced before 1733, by William Houſtoun, M. D.[l] who found it at La Vera Cruz, and ſent the ſeeds to Mr. Miller.

9. Leaflets broader than they are long, and involute: there are two glands at the baſe of the leaf[m].

The leaves dye a very fine black: in october they wither, turn to a dirty crimſon colour, and fall off before the capſules. The young leaves ſhoot out again in march. Each capſule contains three hard black ſhells, the ſize of pepper-corns or common peas, covered entirely with a delicate ſnow-white ſubſtance. It is not this that produces the Tallow, as is commonly ſuppoſed; but it is the oil expreſſed from the kernel, and this white ſubſtance muſt be well cleared from the ſhells before they are broken, for that will conſiderably leſſen the quantity of oil. For this purpoſe the ſhells ſhould remain ten or fifteen days in water to ſoak, and then they may be cleared of the white ſubſtance by rubbing: it will not, however, part from the ſhell without difficulty. The oil drops from the preſs like thick glutinous lamp oil, and ſoon hardens by cold to the conſiſtence of common tallow: by boiling it becomes as hard as bee's-wax[n].

It is a native of China; flowering in may and june, and ripening the ſeeds in november:—it flowers here in ſeptember; and was introduced in 1755, by Hugh Duke of Northumberland[o].

In Chineſe it is named Ko Sheu or Ou Ko, or as the French write it U-kieu.

10. Stem ſubangular, naked at bottom, tomentoſe at top, ſimple, a foot high and more. Leaves alternate, petioled, green above, yellowiſh beneath, netted all over with the veins, growing gradually ſmaller towards the top, the uppermoſt tomentoſe. Flowers terminating in ſpikes, which are peduncled, tomentoſe, and the length of the finger[p].

It bears a great reſemblance to *C. febiſerum*, but the leaves are much larger, more acuminate, with five nerves running from the baſe: the panicle is villoſe, divided into racemes, and pyramidal[q].

Native of Japan: flowering in july and auguſt[r].

11. Stem angular, ſimple, ſmooth. Leaves alternate, petioled, unequally ſerrate, ſmooth, two inches wide, and between three and four long. Petioles angular, a finger's length. Two emarginate glands on the edge of the leaf, above the baſe. Flowers in racemes, the males at the end, the females below.

[a] Browne. [b] Houſtoun, in mſcr. cent. [c] Horr. kew. [d] Hort. kew. [e] Linn. ſpec. [f] Browne. [g] D'Aſſo. [h] Horr. kew. from Lobel. [i] Browne. [k] Linn. ſyſt. [l] Horr. kew. [m] Linn. ſyſt. [n] Blake Mſs. ſee Duhalde; and Grofier, p. 438. engl. edit. [o] Hort. kew. [p] Thunberg. [q] Linn. ſuppl. [r] Thunberg.

Raceme axillary, loose, angular, smooth, a palm or span in length. Calyx deeply five-parted, divisions lanceolate, smooth, patulous. Petals white, woolly, the length of the calyx. Filaments about twelve, filiform.—Corolla in the female flowers none. Germ superior, ovate, villose: styles five, filiform: stigmas simple, obtuse. Capsule three-cornered, obtuse, villose, ash-coloured, three-valved, three-celled.—It differs from *C. glandulosum*, in its acute, smooth leaves, and peduncled fruits.—Cultivated in Japan, whither it was brought by the Portugueze. It flowers in september[1].

12. This is a middle-sized tree, with a few spreading branches. Leaves alternate, nerved, on long petioles. Flowers in erect, simple, terminating racemes, scarcely the length of the leaf, the lower ones female, the upper male, pale-coloured; calyx five-leaved, very short, under the capsule reflected. In the males corolla five-petalled, with fifteen stamens; in the females corolla none[2]. Capsule three-cornered-ovate, rather large, coriaceous, thin, smooth, three-grooved, tricoccous. Partitions very thin, almost membranaceous. Seeds convex on one side, very bluntly angular on the other, with a very thin edge, straw-coloured, brown or blackish[3].

Native of the East-Indies, China and Cochinchina.

13. Calyx of the male ten-leaved, imbricate, hirsute within. Corolla none. Stamens twelve.—Calyx of the females five-leaved. Germ hirsute. Styles three, six-parted[4].

It seldom rises above three feet in height; is pretty simple towards the root, and divides into three or four simple branches towards the top. Leaves pointed both ways. Frequent in St. Elizabeth's, Jamaica[5].

14. This is a middle-sized tree, with a few long spreading branches, which according to Burmann are angular and rugged. Leaves subacuminate, unequally toothed, scattered over the branches, tomentose on both sides, on long petioles: from the axils of these, says Burmann, arise smaller branches, bearing smaller leaves on petioles an inch in length. Racemes terminating, and very simple. Flowers white, with five-leaved calyxes; the upper male, villose, with a five-petalled corolla, and from fifteen to twenty stamens; the lower female, tomentose[6]: capsules small, globular, without any groove, tricoccous, with the five-leaved spreading calyx permanent at the base: skin coriaceous, quite entire, white, tomentose on the outside: shells the substance of paper, white, opening elastically. Seeds roundish, turgidly lens-shaped, very obscurely wrinkled, of a brown bay colour[7], the size of hemp.'

The leaves infused in warm water or milk purge and vomit.—It exudes a very fine lac spontaneously; this appears like a bud at the origin of the branches, but sparingly. They use this in Ceylon to varnish their lances, the handles of their tools, &c. It is superior to that which in Pegu and Siam is formed by the ants, and much more pure[8].

Lac is said to exude in small quantities from this and other species; but all that substance which we commonly call Gum Lac in Europe is the work of the red ants, who are supposed to collect or suck the resinous juice from this and perhaps other trees, to digest it with the animal acid in their stomachs, and then to incrust the branches with it, to serve as a nest or comb for their young. It is not properly a gum, resin or oil, not being soluble either in water or fat oils. The use of this substance is well known in dyeing silk and woollens of a scarlet colour, and the leather called Morocco leather, for sealing-wax, varnish, &c. The wood is light, white and brittle. The bark and resin are reputed to be serviceable in ulcers of the mouth, in the gonorrhœa, fluor albus, dysentery, &c.[9]

Native of the East-Indies, as Assam on the borders of Thibet, where the tree is called Bihar; the southern provinces of Cochinchina, and Cambodia.

15. This is an upright, branched, diffused shrub, three or four feet high, very sweet smelling, covered all over with a close yellowish nap, and abounding with a balsamic, thickish, odorous, brownish sap, which exudes wherever a cut or rupture is made. Leaves petioled, green above, ferruginous-yellow underneath, thick, scatteringly alternate, two or three inches long, numerous. Spikes subterminating from the divisions of the younger branchlets. Flowers small, with white petals[1]. It much resembles *C. humile*, but the leaves are not cordate[2].

Native of Martinico, Curaçao and Jamaica.

16. This is a middle-sized tree with spreading branches, subdivided, round, rugged, with minute dots interspersed with other larger ones, tomentose towards the end; hairs stellate. Leaves large, spreading, five-nerved, unequally serrate: the younger ones subtomentose, with stellate hairs, especially underneath, and acuminate, the older ones almost naked, only a little hairy on the veins, beneath rugged, with dots, paler, obtuse. Petioles tomentose, one-third only of the length of the leaf. Stipules bristle-shaped, deciduous. Racemes terminating, quite simple, rather erect, two inches long. Bracte bristle-shaped at the base of each pedicel. Flowers numerous, scattered, villose; the lower female, the upper male: the latter with the leaflets of the calyx ovate and numerous, stamens villose at the base[3]. Capsule ovate or globular, with the short calyx turned back below, smooth, coriaceous, thick, brown, with six paler lines: skin corky, thick. Seeds ovate-oblong, convex on one side, angular on the other, wrinkled, with obscure tubercles of a dark bay colour[4]. Herman collected a lac from the wounded bark, but in small quantities.

Native of the island of Ceylon, and of China near Canton. Gærtner will not allow that it is *Halesea sitorea* of Rumphius.

17. This is a shrub two feet high, with a smooth branching stem: the branches hoary at the end. Leaves alternate, rufous, clammy, with warts terminated by minute white hairs, contiguous at the base: petioles somewhat hairy. Spikes terminating, erect: male flowers above, five to seven, smaller, whitish; calyx five-leaved, leaflets hoary; petals five, white, equal to the calyx; filaments from twenty to twenty-four, anthers compressed, whitish: females below, larger, greenish; calyx five-leaved, leaflets tomentose or hoary; corolla none. Germ three-grooved, hirsute; styles three, contiguous at the base, white, four-parted to the middle; stigmas first white, then rufescent. Capsule tricoccous, somewhat hirsute. Seeds roundish. The smell of the whole herb is strong and balsamic[1]: it is very hot and pungent upon the palate; and is frequently used in baths and fomentations for nervous weaknesses. Native of Jamaica in savannahs about Kingston[2].

18. Branches alternate. Leaves alternate, petioled, naked. Peduncles longer than the leaves. The flowers every where heaped together in the racemes, the males and females mixed. Calyx three-leaved, narrow, white. It is an annual plant, native of Surinam[1].

The seeds were sent to Boerhaave by John Hartogh.

19. This is a tree eight feet in height, with long reclining branches. Leaves alternate, broad, acute or acuminate, toothed, with a repand edge as in *Tussilago*, on long petioles. Flowers white, in short racemes: males above, with a five-cleft calyx, a five-petalled obtuse reflex corolla, and ten stamens;

females

55295

females at the base two or three together, with a five-cleft calyx, and a five-petalled, acute, erect corolla. Capsule smooth and even, bigger than a walnut; a great quantity of oil is extracted from it. Native of Ceylon and the Molucca islands[a].

20. This rises frequently to the height of two or three feet. In size and general form it is like the seventeenth sort, but is easily distinguished by the thickness of its extreme branches, which are pretty soft and luxuriant. All parts of the plant are equally sharp, and sometimes used in resolutive baths. Native of Jamaica, in savannahs about Kingston[b].

21. Found at the Cape of Good Hope by Thunberg[c].

22. Stems round, furrowed, herbaceous, slightly hairy, erect, branched, a foot and half in height. At the top of the stem and ends of the branches come out spikes of flowers five or six inches in length; on the upper half of these are male flowers, which are small, having a five-cleft calyx, and a corolla of five very small petals, both of a purple colour; the females are below, on the same spike; these have no petals, but a roundish germ inclosed in a green many-leaved calyx; the styles are purple, fringed at the end, and permanent. The fruit is smooth, the size of a large pea, or a horse-bean[d].

It is an annual plant, and flowers in july. Houstoun found it commonly about Vera Cruz, and sent the seeds to England in 1730[e].

23. Native of the East-Indies.

24. Shrubby. Flowering in july and august. Native of the West-Indies. Mr. Francis Masson. Introduced 1782[f].

The specific character given of this species in the Kew catalogue is very nearly the same with that which is given by Linnæus of the twentieth.

25. Fructification in a spike; capsules silky, scarlet, hairy. Sent from Ceylon by Koenig[g].

26. This resembles *C. febiferum*, but the leaves are less acuminate; the glands are not on the petiole at the insertion of the leaves, but rather on the margin of the leaf itself, a little above the base; the spikes are elongated, two or three inches in length; the flowers are distinct[h].

Native of the Society and Friendly isles, and the New Hebrides[i].

27. Native of New Caledonia.—There are two other species of Croton found in the isle of Tanna. *Forst.* 551. 552.

28. This is an annual plant, a foot in height. Stem herbaceous, erect, round, glandular, with stellate hairs on each gland, sparingly branched, dichotomous or trichotomous at top: branches patulous, the lower alternate, the upper opposite, or in whorls three together. There are some glands next the stipules on each side. Leaves alternate, except the uppermost, which are opposite from the forks of the branches; they are spreading, subcordate, unequally serrate or toothed, acute, and have a few pedicelled glands near the petiole, but on the edge; they are three-nerved, the nerves papillose-hispid, veined, wrinkled, pale green on both sides, three inches long, two inches and a half broad. Petioles shorter than the leaf, round on one side, grooved on the other, hispid and papillose like the stem. Stipules two, subulate, hairy, permanent. Spikes between the forks of the branchlets terminating, erect, sessile, six lines long. Flowers close, sessile, dusky herbaceous, from one to two lines in length: under each flower a linear hairy bractæ, ciliate on each side, with three glandular hairs, the length of the calyx, permanent. Male flowers above, with a five-leaved calyx, five-petalled corolla, and ten filaments: females below, with a five-leaved calyx, and no corolla. Capsule rugged, rough with hairs. Seeds oblong, gibbous on the outside, within somewhat angular, and scored with a line, having a scar at top, and being of a brown colour.

It is singular in having glands of three different sorts: 1. villiferous vesicles on the stem, branches, petioles, nerves and fruit: 2. a few naked glomerate glands below the axils: 3. pedicelled glands at the base of the leaves, and at the edges of the bractæ. It differs from *C. palustre* in having sessile spikes, not axillary, leaves three-nerved, not plaited, nor the nerves parallel: it differs from *C. glandulosum* in having pedicelled glands.

Native of Guiana. Raised in the Paris garden from seeds sent by Louis Richard. It flowered in 1783, but perished without producing seeds[k].

29. The twenty-ninth sort grows naturally in Jamaica, from whence it was sent me by the late Dr. Houstoun; this rises with a shrubby stalk six or seven feet high, dividing upward into several branches, which are covered with a yellowish down, garnished with long heart-shaped leaves, ending in acute points; these are two inches and a half long, and one broad in their widest part, standing on long foot-stalks, covered on both sides with a woolly down of the same colour as the branches. The flowers are produced on long close spikes at the end of the branches; the male flowers, which are situated on the upper part of the spikes, have white flowers of one leaf, divided into five parts almost to the bottom, and have five taper stamens, situated in the bottom. The female flowers on the lower part of the spikes, have large woolly calyxes, and are succeeded by round capsules.

30. The thirtieth sort rises with a shrubby stalk near four feet high, dividing into many smaller branches, which have a silvery bark, and are garnished with small heart-shaped leaves, about three quarters of an inch long, and half as broad at their base, ending in acute points; these are woolly on both sides, but their under side is silvery, their upper side of a yellowish green. The flowers are produced in short spikes at the end of the branches, are small, white, and have woolly calyxes. The female flowers on the lower part of the spikes are succeeded by roundish capsules.

[31. Native of Hispaniola.

32. Native of Jamaica.

The place of these two is between the fifth and sixth species.

33. Native of the West-Indies. Its place is between the eighth and ninth species.

34, 35. Natives of Jamaica. Their place is between the ninth and tenth species[l].]

36. This rises with a shrubby stem to the height of seven or eight feet, is covered with an ash-coloured bark, and divides at top into many slender branches; some of these are terminated by five or six branchlets, all arising from the same joint; these are naked below, but towards their upper part they have smooth lanceolate leaves, about two inches and a half long, and three quarters of an inch broad, on pretty long foot-stalks; the flowers are produced in short spikes at the ends of the branches, are of an herbaceous colour, and are inclosed in large green calyxes. Native of Jamaica, where it was discovered by Dr. Houstoun.

[37. Native of the West-Indies. The place of this is between the ninth and tenth species[m].

38. Branches smooth, scarred. Leaves approximating towards the top, broad-ovate, unequally tooth-serrate, with stellate fulvous hairs on both sides: petioles the length of the leaves. Raceme terminating, erect, an inch and half long. Peduncle rough with hairs. Calyxes of the females with lanceolate, hairy, tooth-gashed leaflets, and glandular teeth of the males smooth, coloured. Germ rough with hairs[n]. Native of Jamaica, and other parts of the West-Indies. Its place is between the tenth and eleventh species. 31 to 35 inclusive are shrubby; the three last are perennial[o].]

[a] Loureiro. Linn. syst. & Burm. zeyl. [b] Browne. [c] Linn. suppl. [d] Houstoun in Mart. cent. [e] Mart. cent. [f] Hort. kew. [g] Retz. [h] Vahl. [i] Forster.

[k] L'Heritier. [l] Swartz. [m] Ibid. [n] Vahl. [o] Swartz.

Mr. Miller has a Croton under this name, but it is a different ſort. The ſtem is ſhrubby, ſeven or eight feet high, ſending out many irregular branches, covered with an aſh-coloured bark. Leaves heart-ſhaped, near four inches long, and two inches broad in their wideſt part, ending in acute points; they are of a light green on their upper ſide, but woolly on their under, and have ſlender foot-ſtalks; they come out ſingle, and two or three from the ſame joint. The flowers are produced in ſhort ſpikes from the ſide of the branches; they are of a whitiſh green colour. It was ſent from Jamaica by Mr. Robert Millar.

[39. This is a middle-ſized tree, with ſpreading branches. Leaves alternate, ſmooth, white underneath, dotted, whence Loureiro has given this ſpecies the name of *punctatum*, but that having been before occupied by Retzius, I have been compelled to change it; and perhaps after all, this may prove to be no more than a variety of *C. Caſcarilla*, to which Loureiro obſerves it bears a reſemblance, only the leaves are not tomentoſe, and are void of ſmell.—The flowers are white, in ſimple, oblong, terminating racemes, the females at the baſe; both have a five-parted, bell-ſhaped calyx; and five lanceolate-ovate, ſpreading petals, nearly equal to the calyx: the males have fourteen filaments, longer than the corolla: the females have a three-cornered, ſuperior germ, three ſhort ſtyles, and three quadrifid ſtigmas, the clefts filiform, and bent in.

Native of the woods of Cochinchina[e].

40. This is a large tree, with ſpreading branches. The flowers white, in ſimple, terminating racemes. Male flowers at the top: calyx tubular, five-parted, erect; corolla five-petalled, petals ovate, concave, woolly within, equal to the calyx; filaments fifteen, equal to the corolla: females below; calyx five-leaved, leaflets ovate, acute, ſpreading, permanent; corolla none; germ ovate, ſuperior, ſtyle none, ſtigmas three, filiform, ſhort, bifid, reflex. Capſule ovate; ſeeds ovate, tubercled at top. Native of mountain woods in Cochinchina.

The wood is white, heavy, and very durable: it is uſed in building, and for piles of bridges[d].

41. Stem ſuffruticoſe, five feet high, with many reclining branches. Leaves alternate, unequal. The male flowers have eighteen ſtamens; the females are ſucceeded by pendulous capſules; neither have any petals. Native of China, about Canton[e].

42. Stem ſuffruticoſe, round, with divaricating branches; the whole plant clothed with a ſoft nap. Leaves ſcattered, ſubſeſſile, ſilvery underneath, quite entire, ſomewhat channelled, patulous. Male flowers in terminating ſpikes, each flower pedicelled, and having a ſubulate bracte: calyx half-five-cleft, bell-ſhaped: corolla none, except the five yellow nectarous glands placed in a ring at the bottom of the calyx: filaments twelve or thirteen, free or detached, a little longer than the calyx, fixed in the bottom of it, villoſe, green. Female flowers like the males in the calyx and glands, but on a ſeparate individual, in threes, terminating, on ſhort peduncles: germ tomentoſe, globular-three-cornered; ſtyles three, united at the baſe, half-five-cleft: capſule larger than a pea, with one ovate, very ſmooth ſeed in each cell. Before the ſpikes come, this plant much reſembles the Stock-gilliflower, or *Cheiranthus incanus*.

Native of Mexico. Cultivated in the garden of the Duke del Infantado near Madrid; flowering and fruiting all the month of auguſt[f].

43. Branches round, ſomewhat rugged, hoary, hirſute above, as are alſo the leaves, with cloſe ſtellate hairs. Leaves like thoſe of *Heliotropium ſupinum*, wrinkled, rounded at the top, ſoft, hoary, half an inch or more in length. Petiole the length of the leaf; a purple gland at the top, and two underneath at the baſe of the leaf. The inflorescence as in *C. tinctorium* (n. 6). Capſules pendulous, of a violet purple colour. It is by no means a variety of *C. tinctorium*; the leaves of which are rhomboid angular-toothed, ſubrepand flat, the younger ones only having a ſingle plait or two; they are hoary indeed underneath, but with minute, not long, very copious hirſute hairs; the petiole has no gland, there being only the pair at the baſe of the leaf.

Obſerved in Arabia by Forſkal[g].

44. This is allied to the preceding; but the hairs are leſs diſtinct, ſo that the whole plant appears to be tomentoſe; the leaves are narrow, flat, quite entire, and have no glands either on the petiole, or at the baſe of the leaves, which are oblique and narrower on one ſide at the baſe. Native of Egypt[h].

The proper place of theſe two is between the ſixth and ſeventh ſpecies.

45. Branches round, with a brown bark, mealy-villoſe at top. Leaves two or three inches long, attenuated at the end, ſomewhat ſharp at the baſe, three-nerved, netted underneath, and ſlightly tinged with numerous, very minute, ſcarlet pellucid dots, and having a brown gland on each ſide at the inſertion of the petiole, which is an inch and half long and round. Racemes either ſingle, or ſeveral from the topmoſt axils crowded together, two inches long. Peduncle of a yellow ferruginous colour, angular. Flowers ſubſeſſile. Styles reflex. Germ whitiſh, dotted with ſcarlet. Capſules oblong, ſcarlet.

Found in Ceylon by Koenig[i].

46. Branches round, proliferous, ſcaly with meal, and aſh-coloured at top. Leaves heaped at the ends of the branchlets, two inches and more in length, paler underneath, membranaceous, either quite entire or obſcurely and remotely ſerrate, the ſerratures blunt, always quite entire at the baſe. A minute gland by the ſide of the petiole, at its inſertion underneath. Stipules ſubulate, deciduous. Peduncle terminating, erect, ſtriate-angular, covered with farinaceous ſcales, a ſpan long, muricated with fallen flowers. Calyx ſubhirſute. Stamens numerous.

Native of Hainam: obſerved by Dr. Dahl[k]. The place of this and the preceding is between the twelfth and thirteenth ſpecies.

47. This has the appearance of *Betula* or Birch. Branches round, with a purpliſh bark, tomentoſe-hoary at the end. Leaves have ſtellate hairs underneath; the younger ones are hoary, and have a minute pedicelled gland at each ſide of the baſe underneath; petiole ſhorter than the leaf, filiform. Racemes at the end of the branches, but as theſe grow forward, becoming lateral, an inch and half in length, erect. Flowers ſmall, rough with hairs; females below; calyx five-leaved; leaflets linear, blunt. Native of the iſland of St. Thomas in the Eaſt-Indies. The place is between the ſeventeenth and eighteenth ſpecies[l].

48. This is a tall tree, with round branches, tomentoſe and hoary at top. Leaves heaped towards the ends of the branches, alternate, a long ſpan and more in length, the lobes ovate, acute, the middle one elongated; they are ſcarcely toothletted, tomentoſe on both ſides, with ſtellate hairs, ſoft, whiter underneath, the younger ones hoary. Petiole one-third of the length of the leaf. Underneath at the inſertion of the leaf on each ſide is a minute brown ſeſſile gland. Raceme terminating, erect, tomentoſe, about a ſpan in length. Flowers copious, ſcattered, males intermixed with females. Germ hirſute, hoary. Styles three, two-parted. Native of the iſland of Trinidad, found there by von Rhor. Its proper place is between the twenty-firſt and twenty-ſecond ſpecies[m].

49. This is an inodorous, ſhrubby, ſmooth plant, three feet high, the ſtems partly procumbent, partly erect. Leaves petioled, alternate, two inches long. Peduncles axillary and very ſhort, having uſually four males at top, and two females at bottom. Flowers ſmall, green; the petals of the females twice as long as the calyx. Common at Carthagena[n].

[a] Loureiro. [b] Ibid. [c] Ibid.
[d] Cavanilles. [e] Vahl. [f] Ibid. [g] Ibid.
[h] Ibid. [i] Ibid. [k] Jacquin.

30. This is a ſhrub ten feet high, erect, having a pleaſant aromatic ſmell through all parts of it. Leaves green above, but beneath ſilvery and ſhining, varying much in ſize. Spikes cloſe, an inch long, loaded with many male flowers, but having very few females either below them or intermixed with them. Calyx tomentoſe, ſubferruginous. Corolla white. Styles three, branched, the length of the germ, reflex, and embracing it cloſely. The flowers come out in vaſt abundance before the appearance of the leaves, and the males falling off whiten all the ground. Native of Carthagena[a].

31. This is an upright ſhrub, four feet high, but little ſubdivided. Branches round, ſmooth, aſh-coloured. Leaves acute, ſmoothiſh, green on both ſides, beſet with ſilvery hairs, on very ſhort petiolæ, alternate, almoſt three inches long. Peduncles many-flowered, very ſhort, axillary, one or two. Flowers whitiſh, inodorous, hermaphrodite, male and female on the ſame or different plants. The firſt have a three-grooved germ, a ſemitrifid villoſe ſtyle, and oblong petals longer than the five-leaved calyx: the laſt have a corolla the length of the calyx, which is looſe and ſpreading, and a three-grooved ſemitrifid ſtyle, with the ſegments bifid. It flowers in june and july, uſually before the leaves appear. Native of Carthagena[b].

Many of the new ſpecies deſcribed above from ſeveral authors, may hereafter, from a more accurate examination by ſuch as have leiſure and opportunity, turn out either to be varieties, or the ſame ſpecies under different names, in the mean time they are given here on the authority of their reſpective authors.

Gærtner has added two very doubtful ſpecies, of which he thinks one (n. 52.) may be an *Adrachne*, (Andrachne) on account of its twin ſeeds, and ſlightly curved embryo, though it differs from that and all the *Tricoccæ* in the ſtructure of the ſeed. The fruit of the other (n. 53.) does not belong to a *Croton*, but having received it under that name, and not knowing where elſe to place it, he has left it under that genus.

52. Calyx five-leaved, ſmall, turned back below the capſule, which is globular, ſmooth, very obſcurely three-grooved, three-celled, tricoccous. Shells of the ſubſtance of paper, bivalve, elaſtic. In each cell a pair of ſeeds glued together, convex on one ſide, very obtuſely angular on the other: but when ſeparate acutely three-cornered, acuminate at the top and baſe, a ſort of dry berry, violet-coloured or blue purple, of a very ſmooth, even, ſhining ſurface; outer covering membranaceous, ſpongy within, middle bony, ſmall, obliquely cordate, compreſſed; inner membranaceous, pale, faſtened to the albumen.—It is called in Ceylon *Lyan-gheddie*.

53. Capſule globular, terminated by a three-ſided three-tubercled point, ſmooth, without any groove, tricoccous. Rind corky, thick, opening into ſix parts from the baſe. Shells the ſubſtance of paper, elaſtic, white, ovate. Seeds ſolitary, heart-ſhaped, ſomewhat compreſſed, convex on one ſide, on the other flat or ſlightly concave, with an umbilical perforation in the hollow of the heart. Outer covering membranaceous, wrinkled; middle cruſtaceous, brittle, pale ſtraw-colour; inner membranaceous, very thin, brown.—It is called in Ceylon *Kebella* and *Kebbele*; theſe differ only in the colour of the outer covering of the ſeed, which in the former is fulvous or red, in the latter duſky or brown[c].]

PROPAGATION AND CULTURE.

All theſe plants, except the ſixth, are natives of warm countries, and will not thrive in England, unleſs they be tenderly treated. They are all propagated by ſeeds; thoſe which are annual perfect their ſeeds in England; but the ſhrubby ſorts very rarely arrive to that perfection, ſo their ſeeds muſt be procured from the countries where they naturally grow. The ſeeds muſt be ſown on a hot-bed early in the ſpring, and when the plants are fit to remove, they ſhould be each tranſplanted into a ſmall pot, and plunged into a moderate hot-bed of tanner's bark, where they ſhould be ſhaded from the ſun till they have taken freſh root; then they muſt have air admitted to them daily, in proportion to the warmth of the ſeaſon; they muſt alſo be frequently refreſhed with water. After the plants are grown too tall to remain in the frames, they ſhould be removed, either into the ſtove or a glaſs caſe, where there is a hot-bed of tanner's bark, into which the pots ſhould be plunged, and there the annual ſorts will flower and perfect their ſeeds; but the ſhrubby ſorts muſt be removed into the bark-ſtove in the autumn, and during the winter ſeaſon they ſhould have but little water; and the ſtove ſhould be kept in a good temperature of heat, otherwiſe they will not live through the winter in England.

As theſe plants retain their leaves all the year, they make a pretty variety in winter, when they are intermixed with other plants, whoſe leaves are of different forms and colours from theſe.

6. The ſeeds of this plant ſhould be ſown in the autumn, ſoon after they are ripe, in a ſmall pot filled with light earth, and plunged into an old tan-bed in a frame, where they may be ſcreened from cold in the winter; and in the ſpring following the pot ſhould be removed to a freſh hot-bed, which will bring up the plants in a month's time; when theſe are grown large enough to remove, they ſhould be each planted in a ſmall pot, and plunged into a freſh hot-bed, being careful to ſhade the glaſſes daily, until the plants have taken new root; then they ſhould have air daily admitted according to the warmth of the ſeaſon, and but little water given to them: with this management I have had the plants flower and produce good ſeeds here, but never could obtain any with other treatment.

Unleſs the plants are brought forward in a hot-bed, the ſeeds do not ripen in this country. [Moſt of the ſhrubby ſorts may be increaſed by cuttings or layers, or both. C. fincare and Aſtroites will ſtrike very eaſily from cuttings: C. glabellum and ſebiferum not ſo eaſily, but they may be raiſed from layers, when ſeeds cannot be procured from abroad.

Procumbent, ſubfruticoſe, leaves in fives, ſublinear, flowers in heads, five-cleft.

DESCRIPTIONS, *&c.*

Theſe are herbaceous plants. Leaves ſtellate, from four to ſix in a whorl, often linear. Flowers bracted, in cloſe terminating ſpikes, or ſometimes but not ſo commonly in corymbs.]

1. This is an annual plant, which riſes with ſeveral upright ſtalks a foot high, having ſix or ſeven very narrow leaves in whorls at each joint. The flowers grow in cloſe ſpikes at the top, and from the ſides of the branches; they are ſmall, white, not longer than the calyx, and make no great appearance. It flowers in june and july, and the ſeeds ripen in autumn.—Native of the South of France and Italy.

[Cultivated 1659 in the botanic garden at Oxford[a].]

2. This is alſo an annual plant, ſending out ſeveral branching ſtalks from the root, which lie proſtrate. The flowers are produced in long ſpikes at the extremities of the branches; they are very ſmall, and make no great appearance.

[The ſtem is ſometimes erect, and perhaps it is only a variety of the foregoing. *Lin. fyſt.*

Ray obſerves that the firſt differs from this only in the narrowneſs of the leaves and ſpikes, and the general lowneſs and ſmallneſs of the plant.—Native of the South of France and the iſlands of the Archipelago.

Cultivated 1663[b]. It flowers in june and july.

[a] Hort. kew. [b] Ibid, from Ger. emac.

3. Annual. Stems not at all woody, a palm in height, at firſt erect, then ſpreading, at the root diffuſed or proſtrate. Leaves revolute, ſcabrous on the upper ſurface and at the edge; the loweſt ovate, the lower lanceolate, the reſt linear. Spikes terminating, ſolitary, lax. Bractes lanceolate, not keeled. Flowers hirſute, longer than the bractes, yellowiſh white, five-cleft and awned, as in *C. maritima*.—Native of Egypt[c].

4. Native of Spain. Annual.]

5. This is like the ſecond in the appearance of the leaves and ſtalks, but the flowers grow on the ſide of the ſtalks, almoſt in whorls, and make little appearance.

[Stems procumbent, perennial, woody. Leaves lanceolate, ſtiff, acute. Bractes ovate. Corollas five-cleft, awned; anthers black. Flowers triſt, yellowiſh colour; cloſed in the day, opening in the night, and of a ſtrong ſmell[d].—Native of the South of France, Italy, and Sicily.

Cultivated 1640[e]. It flowers in june and july.

6. Root annual. Plant ſmall, glaucous all over[f]. Stems thickiſh, diffuſed. Branches alternate, ſtraight, ſimple. Spikes terminating, like thoſe of the firſt ſpecies[g].

This creeps by the root, and the ſpikes are much larger, longer, and more frequent[h].

Native of the South of France, about Montpellier, and Vienne: alſo in Paleſtine.]

7. This has four-cornered rough prickly ſtalks, which bend downward. The flowers are produced in ſmall cluſters at the ends of the branches; the corolla is blue, and cut into four parts at the top; the capſules are two joined together, with one oblong ſeed in each.

8. This riſes with a ſhrubby branching ſtalk near three feet high; with narrow-lanceolate leaves covered with ſtinging hairs. Flowers pale blue, ſucceeded by twin fruit like the former.

Both are natives of La Vera Cruz in New Spain, whence they were ſent by Dr. Houſtoun. The plants grew in the Chelſea garden very well during the ſummer ſeaſon, but periſhed in the autumn before their ſeeds were ripe.

[9. Root perennial, horizontal, ſtrong, woody. Stem ſuffruticoſe, weak, naked at bottom; branches filiform. Leaves uſually ſix together, ovate-lanceolate, acute, rugged, rolled back on the ſides, on the fruit-bearing branches remote, on the others approximating. Flowers dark, almoſt black, ſome peduncled, others ſeſſile, ſupported by an involucre, which is one-leafed, two-parted, and has ſix or ſeven teeth. The ſeſſile flowers have the calyx or bracte three-toothed: the peduncled flowers have a three-leaved inferior calyx with unequal leaflets. Border of the corolla five-cleft, the ſegments bent in and having a claw at the tip. Filaments five, very ſhort: anthers oblong, two-grooved, dark-coloured. Style ſhorter than the tube, cloven and one part longer than the other: ſtigmas capitate, obtuſe. Capſules two, not opening, connate, one-celled. Seeds ſolitary, oblong.—Native of mount Lebanon, near the ſummit[i].]

PROPAGATION AND CULTURE.

1. 2. 5. 6. Theſe are preſerved in ſome gardens for the ſake of variety: if the ſeeds are ſown on a bed of light earth early in the ſpring, where they are deſigned to remain, they will require no other culture, but to thin them where they are too cloſe, and keep them clean from weeds; or if the ſeeds are permitted to ſcatter, the plants will come up in the ſpring, and require no other treatment; but the fifth ſort will not ripen its ſeeds here, when the autumn is not favourable.

Gramen aculeatum. *Camer. epit.* 745.
β. Phleum ſchœnoides. *Jacqu. obſ. in collect.* 1. *p.* 111. *ic.* 1. *t.* 15.

DESCRIPTION, *&c.*

Root annual. Culms many diffuſed, four inches high, branching, covered with the ſheaths of the leaves, which are ſmooth except at the edge; the upper ones gradually broader. Spike ſubglobular, almoſt faſtigiate, with the flowers almoſt ſeſſile in the boſom of the involucre; which is three-leaved, and a little longer than the ſpike*. Or, as Gærtner expreſſes it, the flowers are in a head, covered by two or three leaves, which are ventricoſe at the baſe, and ſerve it for an involucre. The flowers ſometimes have three ſtamens. The common receptacle is conical and tubercled, covered all over with florets. Seed free, without any groove, looſely ſurrounded by the calyx and corolla, which are both permanent; it is ſomewhat of an elliptic form, compreſſedly lenticular, pale, but where the ſcutellum is, brown or cheſtnut-coloured, ſmooth but not ſhining. The ſcutellum is linear-lanceolate, nearly the ſame length with the ſeed, and placed at one edge of it. The embryo is long, ſubulate and yelloviſh.

This graſs was ſucceſſively named *Schœnus*, *Phleum*, and *Anthoxanthum* by Linnæus. It differs abundantly from the firſt in its ſcutellate embryo: from the ſecond both in the form and ſituation of the calyx and ſcutellum or eſcutcheon: from the third, in its want of the awned nectary, and in its whole habit. It is therefore of a diſtinct genus. Gærtner thinks it might poſſibly have been known to Pliny under the name of *Tragos*; hence and from its bearing ſome ſimilitude to Kali, which is by ſome called *Tragos*, he names it *Antitragus*. Pliny's words are: "Eſt alia herba Tragos, ſemipedem alta, "fruticoſa, fine foliis, puſillis racemis rubentibus, "grano tritici, acuto acumine, & ipſa in maritimis "naſcens." L. 25. *f.* 17. *p.* 440.

This graſs is a native of the South of Europe and Siberia. It is common alſo in Barbary.—Monſ. Thouin introduced it at Kew in 1783. It flowers in auguſt*.

CRYPTOSTOMUM. (*From* Κρυπτω, *to conceal, and* ςομα, *the mouth: becauſe the mouth or opening of the corolla is concealed by the nectary.*)

Lin. gen. Schreb. n. 344. Moutabea. *Aubl.* 274. *Juſſ.* 420.
Claſſ. 5. 1. Pentandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, funnel-form, ventricoſe at the baſe, coloured, with a five-cleft border: *ſegments* lanceolate, unequal.
COR. one-petalled, funnel-form: *tube* very ſhort, inſerted into the throat of the calyx: *border* five-cleft; ſegments lanceolate, acute, unequal, converging.
Nectary faſtened to the baſe of the corolla, broad, arched, cloſing the mouth of the corolla, five-toothed.
STAM. *Filaments* none. *Anthers* five, each inſerted below each toothlet of the nectary.
PIST. *Germ* roundiſh, in the bottom of the calyx. *Style* cylindric, the length of the calyx. *Stigma* capitate.
PER. *Berry* globular, three-celled.
SEEDS ſolitary, ovate, acute, marked with a large *hilum* or ſcar.

ESSENTIAL CHARACTER.

Cal. ventricoſe, five-cleft. Tube of the corolla inſerted into the throat of the calyx, border five-cleft. *Nect.* five-toothed, cloſing the mouth of the corolla. *Berry. Seeds* ſcarred.

SPECIES.

1. Cryptoſtomum guianenſe. *Guiana Cryptoſtomum.*
Moutabea Guianenſis. *Aubl. pl. Guian.* 2. *p.* 680.
Cryptoſtomum guianenſe. *Lin. ſyſt. nat. Gmel.* *p.* 390.

DESCRIPTION, *&c.*

This, which is the only ſpecies known, is a kind of ſpreading ſhrub, which grows in the iſle of Cayenne and in Guiana. Its native name is Aimoutabu.

The root of this ſhrub puts forth ſeveral twiggy and branching ſtems, of the length of five or ſix feet or more. By means of theſe twigs and branches it forms buſhes, more or leſs thick. Theſe branches

* Linn. ſpec. * Linn. ſuppl. * Hort. kew.

are garnished with alternate, nearly sessile, smooth, green, entire, oval leaves, terminating in a point. The flowers are produced in little clusters from the bosoms of the leaves. They exhale an odour much resembling that of the Syringa. The ovary becomes a three-celled yellow berry, each cell containing a kind of Almond, of an agreeable substance and of a gelatinous nature, and which the Creoles are fond of.

CUBÆA.

Scop. Lin. gen. Schreb. n. 702. Tachigali. *Aubl. t.* 143. Tachigalia. *Juss.* 349.

Class. 10. 1. Decandria Monogynia.

Nat. order of *Lomentaceæ. Leguminosæ* Juss.

GENERIC CHARACTER.

Cal. *Perianth* one-leafed, turbinate, spreading, permanent, five-parted: *parts* roundish, concave, four erect, the fifth and lowest larger, declined.

Cor. *Petals* five, oblong, almost equal, furnished with claws, inserted into the neck of the calyx; the three upper ones erect, the two lower declined.

Stam. *Filaments* ten, villose at the base, inserted into the calyx below the petals, the three upper ones shorter, filiform, erect, pressed close to the upper petals; the seven lower ones longer, capillary, incumbent on and longer than the lower petals. *Anthers* oblong.

Pist. *Germ* oblong, pedicelled. *Style* capillary. *Stigma* acute.

Per. *Legume* long, coriaceous, villose, ventricose, obliquely acuminate, one-celled.

Seeds several, somewhat kidney-form.

ESSENTIAL CHARACTER.

Cal. turbinate, five-parted, unequal, permanent. *Petals* five, unequal. *Filaments* villose, three shorter. *Germ* pedicelled. *Legume* villose, six or seven-seeded.

SPECIES.

1. Cubæa paniculara. *Panicled Cubæa.*
   Tachigali paniculata. *Aubl. pl. Guian.* 1. *p.* 372. *t.* 143. *fig.* 1.
2. Cubæa trigona. *Trigonal Cubæa.*
   Tachigali trigona. *Aubl. pl. Guian.* 1. *p.* 374. *t.* 143. *fig.* 2.

DESCRIPTIONS, *&c.*

1. The first of these, or Cubæa paniculata, is a tree of sixty feet high, extremely branchy at top: the branches are thick, the smaller ones or ramulets trigonal, growing in a scattered manner: the leaves are large, alternate, pinnate: the leaflets in six pairs, opposite, subovate, acute, quite entire, green and smooth above, somewhat downy beneath, and of an ash-coloured green: there are two opposite stipules at the base of the leaf-rib: the flowers are spicated, terminal, and disposed into a very ample panicle: the ramulets of the panicle are long, trigonal, and many-flowered. The flowers alternate, subpedunculated. It grows near the banks of rivers. Its native name is Tachigali.

2. This is found in the same situations, and is probably rather a variety of the former than truly distinct; and differs in having the pinnules situated alternately on the triangular midrib.

17. Cucubalus paniculatus.
Mill. dict. n. 12.
Root-leaves ovate, acute, ſtem-leaves lanceolate oppoſite; flowers panicled, erect.

DESCRIPTIONS, *&c.*

1. [Root perennial, creeping, and ſpreading far in the ground. The whole plant ſomewhat hairy. Stems mounting four or five and even eight or ten feet, among buſhes, but trailing if not ſupported; herbaceous, and dying to the root every year: they are cylindric, roughiſh, and of a pleaſant green. Side branches oppoſite at each joint, horizontal or ſlanting downwards; the joints large. The leaves grow oppoſite at every joint, and reſemble thoſe of Chickweed both in ſhape and colour, but are larger and ſoft to the touch, being a little villoſe; they are oval-lanceolate, very entire, on ſhort leaf-ſtalks, thoſe below the branches bent down to the ſtem. Flowers axillary, ſtanding ſingle on ſlender peduncles, and nodding. Calyx ovate, bellying, cloven more than half way down, frequently tinged with purple. Petals ſpreading, white, cloven, claws very narrow, little ears at the baſe of the border, ſerrated at the end; ſo that this, according to ſome authors, is properly a *Silene*. Fruit an oval capſule reſembling a berry, almoſt as large as a ſmall black cherry, very black when ripe, ſmooth, ſhining, ſoft, and full of pulp: at firſt it has three cells, but the partitions being of a looſe texture, they ſoon ſhrivel up, and give the appearance of there being but one cell; it does not open at the point as in *Silene* and this genus. As the fruit enlarges, the calyx becomes more reflex; and when it is at the full ſize, appears open, the calyx being turned back to the peduncle. Seeds from thirty or thirty-five to forty, pedicelled, ſhining, wrinkled, kidney-form, blackiſh*.

I have left this ſpecies where Linnæus has placed it, though Haller and others think that it does not properly belong to this genus. Dr. Stokes has given the following ſpecific character—*ſtem branched, flowers ſolitary from the diviſions of the branches, calyxes bell-ſhaped five-cleft, petals bifid diſtant*: and remarks that its habit is that of *Ceraſtium*, but its general ſtructure that of *Silene*; and that it ſeems to form the connecting link between them.

Native of Germany, Flanders, France, Switzerland, Carniola, Italy, Spain; in woods and hedges. Mr. Ray obſerved it about Frankfort; in Italy and the South of France.—In Britain it has been found only in the Iſle of Angleſea, by Mr. Fowlkes of Llanbeder near Ruthin, a great collector of many rare Britiſh plants which I preſerve in my herbarium.—Johnſon in Gerarde ſpeaks of it as being wild in England, but ſays, that he has not ſeen it growing but in the garden of his friend Mr. Pemble at Marribone.—Parkinſon affirms that he has ſometimes found it by hedge ſides in our own land.—It flowers in june and july.

According to Mr. Miller, the berries are affirmed to be no leſs deadly, than the *Atropa* or deadly Nightſhade itſelf.

2. Root perennial, woody, yellow on the outſide, white within. Plant generally free from hairs. Stem decumbent at the baſe, branched, and dichotomous near the ſummit, round, green or red, a foot or eighteen inches in height; the joints large. Leaves below the forkings of the ſtem connate, frequently tinged with purple; the reſt not properly connate, but ſeſſile in pairs, cordate-lanceolate, very entire, covered on both ſurfaces with numerous pimples; they are ſoft and of a ſea-green colour: ſometimes however they are rough, or fringed with prickle-like hairs, or have a few hairs ſcattered over the ſurface. Flowers, ſome ſolitary at the diviſions of the ſtem, others crowded at the ends of the branches, ſome on long peduncles, nodding. Calyx inflated, longer than the claws of the petals, veined with green or browniſh purple, but ſometimes without veins. Petals white, cleft beyond the middle, diſtant, the ſegments frequently ſlightly ſerrulate; the

* Miller's figures, Withering, Stokes in With. Woodw. Miſſ. Scopoli.

claws having rudiments of a crown, and thus forming a link between this genus and *Silene*. Stamens not longer than the germ, five of them fixed to a glandular nectary at the bottom of the flower, and shedding their farina sooner than the other five, which are fixed to the petals: anthers yellowish, (sometimes purple) with a greenish dirty yellow farina. Germ blackish and smooth, supported by a ten-cornered column: stigma not pubescent. Capsule generally opening six ways, but sometimes five or seven, each valve generally splitting into two teeth: three-celled only at the base. Seeds small, angular, prickly, glaucous-brown [b].

Linnæus informs us, that a female variety is frequent in the Upsal garden; smaller than the hermaphrodite, the calyxes exactly ovate, more dusky, not oblong-ovate, corolla less, stamens shorter by half than the corolla terminated by a tubercle without anthers, styles three or five, longer than the corolla, declining. Both plants are fertile [c].

This species varies with broader and narrower leaves, smooth and hairy; also with a double flower. Hence Mr. Miller has made three species of this:] 1. *C. latifolius*, our English Spatling Poppy, which he defines to have erect smooth stems, and the stamens longer than the corolla. 2. *C. angustifolius*, the Alpine Campion, differing from the foregoing in having much longer and narrower leaves, the stalks more divided and spreading, and the roots not creeping. 3. *C. Behen* (*var. γ. Lin. fl. succ.*); native of Sweden and other northern countries, where it passes for our common sort. The stalks of this are much larger, the leaves longer and more pointed; the calyx curiously veined like net-work, of a purplish colour, whereas that of our common sort is plain.

[Native of almost every part of Europe, in corn fields and dry pastures; flowering in june, july, and august.

According to Linneus, horses, cows, sheep, and goats eat it: Schreber on the contrary says that cattle reject it.—In Gothland, they apply the herb externally in erysipelatous eruptions [d].—The leaves boiled have something of the flavour of Peas, and proved of great use to the inhabitants of Minorca in 1685, when a swarm of locusts had destroyed the harvest [e].

Besides those given above, it has the names of *white corn Campion*, and *white Bottle*.]

3. Root biennial, putting out many succulent leaves near the ground, out of the middle of which arises an upright stalk about fifteen inches high, the lower part of which has leaves of the same form and consistence as those at bottom, but smaller; these are placed opposite; the upper part of the stalk divides into two smaller, on which stand a few small herbaceous flowers at each joint. It flowers in june, and sometimes ripens seeds in autumn.

It was discovered in the Levant by Tournefort, who sent the seeds to the royal garden at Paris. It is a native of Sicily.

[4. Root biennial. Stem very simple, a foot high, erect, firm, round, villose, viscid at top. Root-leaves narrow-lanceolate, almost smooth, acuminate; stem-leaves broader, clasping, viscid-villose, somewhat waved, reflex at the base, not on the sides. Peduncles opposite, short, three-flowered. Flowers decumbent: calyx cylindric, ten-cornered, viscid; petals white, two-parted. Stamens longer than the corolla; anthers greenish. Styles longer than the corolla. The flowers do not all turn one way, as in most of the species, but nod every way, and smell sweet at night. Fruit ovate, one-celled [f].

Native of the Levant, Italy, Carniola, Sweden. Linneus observes that this is one of the many plants common to Sweden and Mount Ararat, as we find from Tournefort's collections.—It is certain that the Dover Campion (*Raii syn.* 340. 12.) is not this plant; but in the opinion of Dr. Stokes, nothing more than a variety of *Silene nutans*, if at all different. Retzius however, who cultivated them in his garden, says that the Dover Camp on is so like *C. italicus* (n. 7.) in all respects, that he cannot distinguish them. The Italian plant indeed is more tender and delicate; that of Dover more stiff, larger, more patient of cold, the petals somewhat deeper cloven and not flamed underneath as the Italian is, but these differences not being sufficient to constitute a specific distinction, he regards them as varieties.—Mr. Miller says the root is perennial, the corolla pale red, and that it flowers in june.]

5. The fifth sort grows naturally in Virginia and Canada. This has a perennial root, from which arise two or three slender upright stalks about a foot high, their lower part having four leaves at each joint, placed in form of a cross; these are smooth, of a deep green, about an inch and an half long, and half an inch broad near their base, terminating in acute points; the joints of the upper part of the stalk have white fringed flowers, standing single upon pretty long peduncles, which come out by pairs opposite. The flowers appear in june, and in warm seasons the seeds will ripen in England.

[Petals four-cleft, with two-parted lobes; and having no crown [g].

Cultivated in 1768, by Mr. Miller [h].

6. Stem weak, branching, spread upon the ground. Leaves linear (not smooth), the younger ones ciliate at the base. Flowers axillary, solitary, sessile. Calyx cylindric, in the fruit obovate, ten-cornered, with the interstices membranaceous, the teeth small. Petals minute, hardly longer than the calyx. Styles often four.—Found in Egypt, by Hasselquist [i].]

7. Stem about two feet high, viscid, and from each joint two side branches, under which are situated two very narrow leaves; it spreads out and forms a sort of panicle at top, the stem and branches being terminated by clusters of greenish flowers.

[Biennial. Leaves lanceolate, bluntish, pointing one way. Stem, especially at bottom, hoary with a scarcely visible cotton. Flowers on peduncles, erect: calyxes club-shaped, marked with ten grooves. Petals broadish, white, beneath lead colour [k].

Jacquin observes, that the branches are dichotomous; the leaves less tomentose than the stem, sessile, some bluntish others pointed, the upper ones almost linear [l] and the stamens concolor with the pistil inclining towards the ground.

Retzius considers our Dover Campion as a variety of this. See n. 4.

Native of Italy. Cultivated 1768, by Mr. Miller [l]. It flowers in may and june, and the seeds ripen in autumn.

8. Native of Russia. Introduced about 1772. It flowers from june to august; and is perennial [m].

9. Stamens longer than the flower.—Native of Siberia [n]. Introduced 1773, by Chevalier Murray. It flowers from june to august; and is perennial [o].]

10. This is a perennial plant, sending out many long leaves near the ground, between these arise round viscid stalks three feet high (or from eighteen inches to that height), having at each joint two long narrow leaves, ending in acute points. The stalks branch out into many divisions, on the upper parts of which the peduncles arise from each joint by pairs opposite; each of these sustains three or four flowers of an herbaceous colour. [To this we may add, that the stems are erect or nearly so, glaucous, very smooth and thick. Leaves sessile, waved, glaucous, smooth, quite entire, only on the lower part of the stem, and connate. Flowers in a nodding panicle: calyx ventricose, inflated, not sinuated or angular: petals white: anthers reddish: styles white: capsule subglobular [p]. Linneus affirms, that the calyx is dusky or brown; Krocker says, it is either of a very pale whitish bay, or else greenish and glaucous netted with bay-coloured veins.

Cultivated

Native of Italy, Sicily, and Silesia. Cultivated 1711, in the botanic garden at Chelsea[8]. It flowers in auguſt.

β. Perennial. Root-leaves many, oblong, narrow (the firſt broader) ſmooth, without veins. Stems two feet high and more, round, ſmooth, purpliſh towards the top, glaucous, not viſcid: towards the middle and upper part come out branches in pairs, of a purpliſh green colour, dividing into others that are ſimilar, which put forth flowers in june and july: calyxes oblong, cylindric, ſmooth, pale, glaucous; corollas herbaceous or yelloviſh green, petals narrow, divided to the middle, opening at night. Five of the ſtamens come out firſt, and afterwards the five others; anthers greeniſh. Capſule ſix-valved. At firſt the flowers are crowded into an oblong, pendulous ſpike; then they become looſer and form a thin nodding panicle; and when the ſeeds grow ripe, the whole panicle becomes erect.—It was ſent over by Boerhaave, and cultivated in the Eltham garden[1].

11. Stems many, rather ſtiff, erect, a foot high, ſomewhat tomentoſe, very ſoft: branches at bottom alternate, ſhorter. Stems mixed with thoſe which are barren, ſhorter by half than the others, erect; crowded with leaves at the end. Lower leaves ſpatulate; the reſt lanceolate; all ſomewhat fleſhy, very ſoft, tomentoſe, bluntiſh, ſomewhat reflected at the end, ſpreading. Panicle brachiate, with dichotomous branches, (*mant.*). Calyxes obtuſely toothed, club-ſhaped, erect, very ſoft. Flowers white, erect; borders ſhorter than the calyx, cloven half way; claws longer than the calyx. Stamens the length of the calyx. Styles longer than the corolla. Perennial, ſhrubby.—Native of the ſea coaſts of Italy[2].

12. Root long, fuſiform, ſlender. The root-leaves form a thick tuft, and are wedge-ſhaped, or rather ſpatulate, entire and acuminate, diminiſhing into a long channelled foot-ſtalk: they are clammy, and rough with minute, thick-ſet, curved, and ſometimes ſtellated hairs. From theſe ariſe one or ſeveral ſtems, from one to two feet high, upright, the lower part cloathed with a few oppoſite leaves, ſhaped like the root-leaves, the upper part is naked and clammy; at the bottom of the panicle are two membranaceous connate bractes, and the ſame under each ſet of flower-ſtalks. The lower part of the panicle both of the male and female flowers conſiſts of oppoſite branches, each topped with a kind of umbel (to which the two bracteal leaves form a ſort of general involucre) of ſeſſile flowers, and others each on a ſingle peduncle; ſome of the umbels are proliferous, and bear ſecond, and theſe again third umbels. The male flowers often produce abortive piſtils, and the females abortive ſtamens. The male plants bear more flowers, and in cloſer panicles than the female. Capſules long, elliptical[3], ſix-valved[4]. Calyx ſtreaked with green lines. Corolla pale green, or herbaceous-yellow: petals narrow, linear, very entire, a little bent in at the tip. Five filaments longer and five ſhorter than the corolla. Styles three[5], or rather varying from three to five[6]. *Pollich ſays that the flowers he deſcribes are hermaphrodite: ſuch are rarely ſeen with us.*

The male plant, ſays Haller, has a larger flower, and a reddiſh calyx: the female has a ſmaller flower, and a green calyx.]

The male plants often grow four or five feet high; but thoſe of the female are ſeldom above three feet. The flowers of the former are produced in looſe ſpikes from the lower joints of the ſtalk, but on the upper part, they ſtand in ſingle peduncles in cluſters quite round the ſtalks; theſe are ſmall, and of a greeniſh colour. The female plants have three or four flowers growing upon each peduncle, which ariſes from the ſide of the ſtalk.

[According to Scopoli, the male flowers are apetalous, and have the rudiment of a three-ſtyled germ. With us both ſexes have the ſame narrow entire yelloviſh petals.—In Tartary it is found with a hermaphrodite flower.

Native of Germany, Denmark, Switzerland, the Valais, France, Italy, Carniola, Spain, Siberia, England, in gravelly and ſandy ſoils: as in gravel pits, on the north ſide of Newmarket, about Chippenham. Beyond Barton Mills in the way to Brandon, and beyond Brandon in the road to Hillborough. Near Swaffham and Narborough, Norfolk.—It flowers in july and auguſt. It is marked by Linneus, Villars, Krocker, *&c.* as perennial. Miller ſays biennial: and ſo it is marked in the Kew catalogue.

Gerarde calls it great Baſtard Weld or Woade: he had the ſeeds from Padua, and expected the flowers 1597.—Parkinſon names it greater Spaniſh Catchfly. They did not know that it was a native of England; Ray ſeems firſt to have noticed this.

Ray alſo ſays, it is known in Suffolk by the name of Star of the Earth, and is in great repute as a remedy for the Hydrophobia. See hiſt. p. 1895. and Philoſ. tranſ. n. 187. Though Ray has no doubt of its efficacy, we ſhould be ſorry now to depend on ſuch a remedy in ſuch a diſorder.

13. Linneus deſires that this may be compared with *Silene mutabilis*, of which perhaps it may be only a variety.

According to Moriſon, the ſtem is a foot high, and erect; two narrow hirſute leaves at each joint: towards the top it bears white flowers, with narrow petals cloven to the middle, all turned one way; capſules oblong, hirſute on the outſide; ſeeds blackiſh.

Magnol thus deſcribes his plant: root white, fibrous. Stem (ſometimes there are two) a palm and half in height. Root-leaves form a tuft on the ground, like thoſe of Daiſy, and are hairy; ſtem-leaves two oppoſite at each joint, narrow and oblong. At the top of the ſtem a ſpike of flowers, bent down at firſt like a Scorpion's tail, but gradually becoming erect, after the flowers fall. Petals whitiſh, deeply cloven, bending inwards when they begin to wither. It is an annual plant. Linneus marks it as perennial.

Native of Montpellier.—Ray found Moriſon's plant about Naples, and Meſſina.

14. Root perennial. Stem a palm in height, with linear leaflets. Every calyx is ſeſſile between two leaflets, and from the axils of theſe other petioles frequently ariſe, and therefore it is not between two ſcales as in the genus Dianthus.—Native of the Levant[7].

15. Root-leaves forming a tuft, linear, obtuſe, ſmooth and even. Stem very ſimple and ſhort, bearing one flower, but having often three joints. Calyx oblong, bell-ſhaped, patulous, obtuſe, pubeſcent, the length of the ſtem[8]. Corolla red, the borders elliptic: germ ſeſſile: ſtyles ſhort[9].—Near Geneva. In Styria, and the mountains bordering on Carinthia. Mountains of Italy and Moravia. Perennial.

16. Root flowering the ſecond year. Stems erect, dichotomous, ſomewhat villoſe, here and there covered with a tenacious viſcid juice. Leaves lanceolate, acute, very entire, hiſpid, eſpecially the midrib; the upper ones linear. Calyx funnel-form, ten-angled, viſcid, when fruit-bearing club-ſhaped. Corolla greeniſh white; claws the length of the calyx, border cloven almoſt to the baſe. Stamens ſtraight, the length of the corolla or rather longer; anthers incumbent. Germ pedicelled, cylindric, obtuſe, higher than the calyx; ſtyles three diverging; ſtigmas very ſimple, obtuſe. Capſule globular (having a club-ſhaped appearance on account of the pedicel) half-three-celled, opening with a ſix-toothed, revolute top. Seeds kidney form[10].—Retzius doubts whether the Lychnis viſcoſa Scop. 518. (ſee n. 4.) be different from this.]

17. This

17. This is a biennial plant. Root-leaves many, on long petioles. From among theſe ariſes an upright ſtalk, ſending out two oppoſite ſide-branches at each joint; under each of theſe is one lanceolate acute leaf. Theſe ſide-branches, and alſo the upright ſtems are terminated by whitiſh flowers, formed into a panicle, and ſtanding erect. They appear in june, and are ſucceeded by ſeeds which ripen in autumn.—Native of Spain and Italy, whence Mr. Miller had the ſeeds. He cultivated it in 1759.

PROPAGATION AND CULTURE.

1. Delights in ſhade, and will thrive in almoſt any ſoil. It is apt to multiply too faſt by its creeping roots.

2. A rambling weed, and ſeldom cultivated. The root ſtrikes ſo deep into the ground, as not eaſily to be deſtroyed by the plough; and therefore it is frequently ſeen growing in bunches among corn.

3. The plant is biennial, generally periſhing when it has produced ſeeds; but unleſs it is ſown upon very dry rubbiſh, and in a warm ſituation, the plants will not live through the winter in England; for when they are in good ground they grow large, and are ſo repleté with moiſture, as to be affected by the firſt froſt in the autumn; but where they have grown upon an old wall, I have known them eſcape, when all thoſe were killed which grew in the ground.

7 to 10, 12, *&c.* Theſe are propagated by ſeeds, which ſhould be ſown where the plants are deſigned to remain; for as they ſend out long top roots, they do not bear tranſplanting, unleſs it is performed while the plants are young. The twelfth is very hardy, and will thrive in almoſt any ſoil or ſituation, but agrees beſt with a dry ſoil. It is neceſſary to have ſome male plants among the females, to have perfect ſeeds.

DESCRIPTIONS, *&c.*

These are all annual plants, with herbaceous scandent stems. The leaves of *Colocynthis* and *Anguria* are palmate-laciniate, in the other species they are heart-shaped. Peduncles short, one or many-flowered. Fruit of *Colocynthis* ovate, of a comparatively smaller size, with a dry bitter pulp or flesh not eatable: of *Anguria* smaller than any of the rest, echinate on the outside, within pulpy, watery, eatable: of *Melon* ovate, fleshy, sweet, with a grooved or netted surface: of *Cucumber* oblong, subcylindric, the surface unequal, within fleshy, insipid[a].

1. Coloquintida has leaves of a dark green, rough, and deeply laciniated in the manner of those of the Citrul, but smaller: the stems are rough, and trailing, like those of Bryony. The flowers are rather small and of a dull yellowish colour: the fruit is round; of the size of an Orange; it is green at first, but grows yellow when quite ripe: the pulp or internal part is light, spongy, and white, and is most intensely and intolerably bitter: it is this substance dried which is the Coloquintida of the shops. Its native place is unknown.

Gerarde says, it has been delivered unto him for a truth, that Coloquintida grows in the sands of the Mediterranean sea shore wild, especially at that side of Barbary, as also without the mouth of the straits near to Santa Cruz, *&c.*

It flowers from may to august. Cultivated in 1551[b].

2. The plant is smaller in every part than the common Melon, and has a nauseous odour: the stem and footstalks are rough and angular: the leaves are cordate, rough beneath, five-lobed, and toothed: the intermediate lobe nearly twice the length of the others: the peduncles are one-flowered: the fruits are smooth, but are armed with soft and innocent prickles scattered upon them. They are variegated with uncertain streaks, alternately greenish and yellowish: their bitterness equals that of Coloquintida[c].

Native of the Levant; flowering from june to september. Introduced 1777, by Jos. Nic. de Jacquin, M. D.[a]

3. Flowers small, like those of Bryony. Stems angular hispid[d].

The fruit of this sort is eaten when green by the inhabitants of the West Indian islands, where it is indigenous, as Cucumbers; but these are far inferior to our common Cucumber. The fruit seldom grows so large as a pullet's egg, and is in shape like it; but the rind is closely beset with blunt prickles, somewhat like the skin of a hedgehog: where it is exposed to the full air, it is of a dark green colour, but when it is closely covered, either by the leaves or weeds, it is white[e]. The fruit is frequently used in the sugar islands, with other herbs, in soups; and is esteemed an agreeable and wholesome ingredient in them[b].

It flowers in july and august; and was cultivated by Mr. Miller in 1755[f].

4. Stems numerous, somewhat angular, prostrate. Leaves five-cleft. Flowers small.—Native of the Cape of Good Hope[g].

5. Flowers yellow; males terminating, on many-flowered peduncles: females lateral, solitary. Leaves cordate, sharply angular, serrate-toothed, hairy. Stem five-cornered, acute, climbing. Fruits ovate or oblong, obtuse, five inches long, brownish-yellow, smooth. Seeds suboval, compressed, smooth, black, looking as if they had been chewed, as in Anguria[i]. The fruit is very insipid, but it is eaten boiled and pickled.

Native of India. Flowering from june to september. Cultivated 1692, by Bishop Compton[a].

6. Melon or Musk Melon has the stems procumbent or trailing to a great length, and very much branched, furnished with tendrils for climbing. Leaves palmate-sinuate, or entire, waving about the edge and slightly toothed, with rounded corners; rough with bristles. Flowers pale yellow, lateral, solitary. Calyx covered with white hairs. Corolla wrinkled, ribbed, and having bristles along the ribs on the outside. The female flowers, as they are commonly called, have four large anthers, and the germ is subglobular and covered with white hairs. This discovery of the flowers commonly called females being real hermaphrodites with fertile anthers, as they seem to be, makes it probably less necessary to carry the males to them, as practised by some gardeners, though nature having provided male flowers, it is most likely that the pollen in the anthers of the others is frequently defective.—Fruit roundish or oval, blunt, commonly furrowed longitudinally, sometimes netted, sometimes warted or carbuncled, from four to ten or twelve inches in length and diameter, yellowish green or white; pulp firm, musky, reddish seldom green. Seeds many, oblong, pale, in a watery pulp. It was first introduced into Europe from Persia.

It has lately been affirmed that it is a native of Calmuc Tartary: but it is difficult to determine the original country of those plants which have been cultivated time immemorial. It appears from Lobel to have been cultivated in England before 1570.

Gerarde (1597) says, that he has seen at the Queen's house at Saint James very many of his first sort (green with a red flesh) ripe, through the diligent and curious nourishing of them by a skilful gentleman the keeper of the said house, called Master Fowle; and in other places near unto the right honorable, the Lord of Suffex house of Bermondsey by London, where from year to year there is very great plenty, especially if the weather be any thing temperate.

Parkinson (1629) informs us that Melons have been only eaten by great personages, because the fruit was not only delicate but rare; and therefore divers were brought from France, and since were nursed up by the kings or noblemens gardiners only: but now divers others that have skill and conveniency of ground for them do plant them and make them more common.

7. The lower leaves roundish, the upper somewhat angular, both toothed about the edge, somewhat hirsute, paler underneath. Flowers yellow, divided into five or six roundish segments, slightly crenate on the edge. Fruit the size and form of an Orange; the rind smooth, sometimes sparingly warted, slightly furrowed only at top, variegated with green and dark orange, and oblong unequal green spots, when the fruit is full ripe becoming yellow and at length whitish: it has a very fragrant vinous musky smell, and a whitish, flaccid, insipid pulp[a].

It is a native of the Levant. Dillenius says that the seeds which grew in the Eltham garden (1732) were reported to come from Morocco, and were received from Mr. Peter Collinson, who had them from Lord Petre. It flowers in july and august.

8. Stems decumbent, cirrhose, obscurely five-cornered. The whole plant covered close and thick with soft, white, pellucid hairs, like the germ in the common Melon, which differs from this in being rough with stiffish, conical, distant hairs. The

fruit ſwells in the middle, is rough, with erect, white hairs, and has a beak at each end[1]. In the fertile earth round Cairo, after the inundation of the Nile, and no where elſe in Egypt.—Linnæus ſays Egypt and Arabia.—Native of the Levant[2].

The fruit is rather watery; the fleſh almoſt of the ſame ſubſtance with the Melon; the taſte ſomewhat ſweet and cool, but not ſo cool as the water melon. The grandees and Europeans in Egypt eat it as the moſt pleaſant fruit they have, and that from which they have leaſt to apprehend[3]. With us it is very indifferent. Cultivated in 1768, by Mr. Miller[4].

9. The common Cucumber, ſo generally cultivated for the table, is ſo well known, ſays Mr. Miller, as not to require a particular deſcription. [We may however remark, that the leaves differ from thoſe of the Melon very much in their form, running out into ſharp angles, eſpecially at the end, with the line between the angles ſtraight, having the nerves prominent on the upper ſurface, and very rough, with briſtles; they are alſo of a firmer texture. In the flowers the ſegments of the calyx are much longer; the corolla of a deeper yellow, each petal or part much wrinkled, commonly rolled in at the edges, the ribs at the back briſtly as in the Melon, and the principal rib ending in a long green point: there are no veſtiges of anthers in the female flowers, and the germ is very oblong, angular but obſcurely, not hairy, but muricated with prickles ariſing from a ſmooth warty ſubſtance: in ſome of the highly-cultivated varieties this natural pricklineſs vaniſhes.

The principal varieties are the following:

1. Common rough green prickly.—Six or ſeven inches long, with a dark green ſkin, cloſely ſet with ſmall prickles. Hardy, a plentiful bearer, but does not fruit early.

2. Short green prickly.—Three or four inches long. Skin rather ſmooth, but having ſmall black prickles. One of the hardieſt and earlieſt ſorts.

3. Long green prickly.—From ſix to eight or nine inches long, thinly ſet with prickles. This is a good bearer, and the beſt for the main crops. There is a variety of this with white fruit.

4. Early green cluſter.—Shortiſh, early, and remarkable for the flowers appearing in cluſters.]

5. Long ſmooth green Turkey.—The ſtalks and leaves much larger than the former ſorts. The fruit is generally twice the length (ten to fifteen inches), and has a ſmooth rind without prickles.

6. Long ſmooth white Turkey.—Differs little from the foregoing, except in colour. It is, however, leſs watery, and is therefore generally better eſteemed.

[7. Large ſmooth green Roman.—The plants are very ſtrong; and the fruit large, long, and quite ſmooth.]

8. Long white prickly Dutch.—Fruit eight or ten inches long, white, with ſmall black prickles. A bad bearer, at leaſt with us, and not ſo hardy as the common ſorts; but the fruit is leſs watery, and has fewer ſeeds.

[The four laſt varieties are all, indeed, but indifferent bearers; but the fruit being very large, handſome, and well taſted, ſome plants ſhould be admitted where there is room.

Parkinſon (parad. 1629.) enumerates the long green—the ſhort—the long yellow—the early ripe or French—the Dantſicke—the Muſcovie. He alſo informs us, that pickled Cucumbers, which were then much uſed for ſauce all winter long, came from beyond ſea; and though ſome ſtrove to equal them, yet theſe were nothing comparable to the former.

Ray, in his travels, obſerves that in Italy they call our Cucumbers *Citrulli*; and water Melons and Pompions *Cucumeri*. In Spaniſh it is called *Cohombro*; in French *Concombre*; in Swediſh *Gurka*; in Daniſh *Agurke*, *Agurke*; in Dutch *Komkommer*; in German *Gurke*, *Kukummer*.

10. Flowers ſmaller than others of the genus, and with a long tube: leaves a palm long and broad; divided, but not very deeply, into five or ſeven ſegments, obſcurely toothed at the edges. The flowers ſcarce exceed the ſize of Jeſſamine flowers. The fruit or Cucumber is three feet, or three feet and a half long; it is never ſtraight, but ſtrangely twiſted, ſo as to reſemble a ſnake: it is externally of a grayiſh green, and grows very red in time. The odour is rank, and the taſte bitter[5].

11. Fruit the ſize of a large pear, of an oblong cylindric form, ſmooth, even, eatable and delicious. It is cultivated about Nagaſaki and elſewhere in Japan; is ripe in June, and is called by the Dutch Banket-Melon[6]. Cultivated 1597[7].

12. Stem decumbent, ſtriated, hiſpid with ſcattered hairs, as are the petioles. Leaves cordate, nerved, pale underneath, rough, with hairs on both ſides, eſpecially the nerves underneath. Flowers axillary, pedunculed, aggregate, yellow. Peduncles very ſhort, hiſpid. Fruit the ſize of a man's head, or larger, oblong. It is cultivated every where in Japan: the fruit preſerved is ſold under the name of *Connemon*, and is a common food among the Japoneſe; it is alſo frequently eaten by the Dutch at Batavia, and is ſometimes brought to Holland[8].

13. Stem herbaceous, ſlender, angular. Leaves frequently angular at the baſe, oblong, acute, ſmooth[9]. Loureiro ſays, it is very nearly allied to Melothria. According to him, the ſtem is round, ſlender, branched, climbing. Leaves roundiſh, petioled, alternate, ſmall. Flowers white, axillary, on many-flowered peduncles. Fruit half an inch in diameter, yellow.—Native of Ceylon and other parts of the Eaſt-Indies, of Cochinchina, and alſo of the Cape of Good Hope.

Virtues.

The plants of this genus in general, or, to ſpeak more properly, of this natural tribe, are conſidered as cooling: the ſpecies moſt in uſe is the C. ſativus, or common Cucumber: this, however, when it is too large, or advanced beyond a certain period of its growth, acquires a bitterneſs, and then becomes unwholeſome. The Melon alſo under certain circumſtances is apt to diſagree, unleſs corrected by ingredients of a warming nature, as pepper, &c. The Citrul or water melon is much eſteemed as a cooling food in the warmer climates. The ſeeds of melons, cucumbers, &c. were formerly uſed in medicine, under the title of the cold ſeeds, in emulſions, &c. Coloquintida, or the dried pulp of the C. Colocynthis, is an extremely ſtrong and irritating cathartic, and has been ſometimes commended not only as an efficacious purgative, but alſo as an alterative, in obſtinate chronical diſorders; others, however, have conſidered it as a dangerous drug: its principal uſe has been that of a ſtimulus to other purgative medicines: thus an extract of Colocynth has been ſometimes ordered in conjunction with aloes; and for mixing with various purgative pills, &c.

PROPAGATION AND CULTURE.

1 to 5. and 10 to 13. Being annual plants, are raiſed from ſeed: and coming from hot or warm climates, require the protection of the dry or bark ſtove; eſpecially the third, which is a native of the Weſt-Indies.]

6. THE MELON.

Varieties or ſorts.—There is a great variety of this fruit cultivated in the different parts of the world, and in this country there are too many of them propagated, which are of no value, eſpecially by thoſe who ſupply the markets, where their ſize is chiefly regarded; ſo that by endeavouring to augment their bulk, the fruit is rendered of no value; I ſhall therefore only mention a very few of the varieties, which are the moſt deſerving of care, excluding the common Melons, as being unworthy of the trouble and expence in cultivating.

1. The ſort of Melon which is in the greateſt eſteem among all the curious in every part of Europe, is the Cantaleupe; which is ſo called from a place about fourteen miles from Rome, where the

[1] Rumphius. [2] Thunberg. [3] Hort. kew. from Ger. [4] Thunberg. [5] Linn. ſyſt.

pope

pope has a country ſeat, in which place this fruit has been long cultivated; but it was brought thither from that part of Armenia which borders on Perſia, where this fruit is in ſo great plenty, that a horſe-load is ſold for a French crown. The fleſh of this Melon, when in perfection, is delicious, and does not offend the moſt tender ſtomachs, but may be eaten with ſafety. The Dutch are ſo fond of this fruit, as to cultivate very few other ſorts, and by way of pre-eminence, call it only by the appellation of Cantaleupe, and never join the title of Melon to it, which they apply indifferently to all the other ſorts. The outer coat of this is very rough, and full of knobs and protuberances like warts; it is of a middling ſize, rather round than long, and the fleſh is for the moſt part of an Orange colour, though there are ſome with a greeniſh fleſh, but I have never met with any of that colour ſo good as thoſe of the other.

2. The Romana is by ſome much eſteemed, and when the fruit is well conditioned, the plants in perfect health, and the ſeaſon dry, it is a good Melon, and may be brought forwarder in the ſeaſon than the Cantaleupe; therefore thoſe who are deſirous of early Melons may cultivate this ſort.

3. The Succado is alſo a good ſort, and may be cultivated for early fruit, but theſe muſt give way to the Cantaleupe, when that is in ſeaſon.

4. The Zatte is alſo a very good Melon, but very ſmall. The fruit of this is ſeldom bigger than a large orange; it is a little flatted at the two ends, and the outer coat is warted like the Cantaleupe, but there is ſo little fleſh in one of theſe fruit, that they are ſcarce worthy the trouble of propagating.

5. The ſmall Portugal Melon, which is by ſome called the Dormer Melon, is a pretty good fruit, and the plants generally producing them in plenty; by many people this is preferred to moſt other, eſpecially thoſe who love a plenty, and are not ſo nice in diſtinguiſhing the quality: this may alſo be cultivated for an early crop.

6. But the beſt Melon for this purpoſe is the Black Galloway, which was brought from Portugal by Lord Galloway many years ſince, but of late years is rarely to be met with in England, it having degenerated by growing among other ſorts. The fruit of this ſort will ripen in a ſhorter time from its firſt ſetting, than any other which I have yet ſeen; and when ſuffered to ripen naturally, is not a bad fruit.

Of the ſeeds.—The few varieties here mentioned, are ſufficient to ſatisfy the curious, and there are ſcarce any other which deſerve the trouble; indeed thoſe who have a true taſte for this fruit, ſeldom cultivate any but the Cantaleupe; but as I before obſerved, where this fruit is deſired early in the ſeaſon, the Cantaleupe is not ſo proper as ſome of the other, therefore a few plants of one of the other ſorts ſhould be raiſed earlier in the ſpring, but ſhould be in a different part of the garden from the Cantaleupe Melons; for when two ſorts of Melons grow near, they cannot be preſerved perfectly right; therefore the Dutch and German gardeners are very careful in this reſpect, and in order to keep the ſort in perfection, do not plant any other ſort of Melon, Cucumber, or Gourd, near theſe, leſt, by the impregnation of the farina of thoſe other, theſe fruit ſhould be rendered bad; and in this particular I am convinced, from long experience, they are right; and from the not obſerving this, many perſons who are lovers of this fruit, have gradually diminiſhed their goodneſs, without knowing the cauſe, and have imputed it to the long cultivating from the ſeeds ſaved in the ſame garden, believing it abſolutely neceſſary to procure ſeeds from a diſtant place frequently to preſerve them good: indeed, where a perſon can ſecurely depend on the care and ſkill of thoſe he procures the ſeeds from, it is a very good method to exchange ſeeds now and then; but there are ſo few who are exact in making choice of the fruits from which they ſave the ſeeds, or careful enough to do it themſelves, but often depend on others to clean the ſeed, that I ſhould adviſe every one to do it himſelf, which is the ſure way to have it good; for I have frequently been deceived myſelf, by depending on the fidelity and ſkill of others; nor could I procure any of theſe ſeeds from Cantaleupe which were good, until my much honoured friend the Chevalier Rathgeb ſent me plentifully of it from thence; though I had often been ſupplied with ſeeds by perſons who I thought could not be deceived in their choice, and who lived near the place of their growth.

Before I quit this head, I beg leave to caution all perſons againſt depending upon ſeeds which are brought from abroad, either by thoſe perſons who import them for ſale, or gentlemen who frequently bring or ſend over theſe ſeeds to their friends, for it ſeldom happens that any of theſe prove tolerable. I have been ſo often deceived by theſe myſelf, as to determine never to make trial of any of theſe ſeeds again, unleſs I receive them from a perſon who is ſkilful, and who eat of the fruit himſelf of which he ſaved the ſeeds; for in Italy, Spain, Portugal, and many parts of France, the gardeners are very careleſs in the choice of all their ſeeds, but of the Melons they are remarkably ſo; and as for thoſe which come from Conſtantinople, Aleppo, and other parts of Turkey, I have rarely ſeen one Melon produced from thoſe ſeeds which was tolerable.

The ſeeds of Melons ſhould not be ſown until they are three years old, nor would I chuſe to ſow them when they are more than ſix; for although they will grow at ten or twelve years old, yet the fruit which are produced from thoſe old ſeeds are ſeldom ſo thick fleſhed as thoſe which come from ſeeds which are freſher: and it is the ſame of light ſeeds, which ſwim upon water when they are taken out of the pulp, for I have made ſome trials of theſe, and have had them grow at three years old; but not one of the Melons produced on theſe plants was near ſo deep fleſhed, as thoſe which grew upon plants raiſed from heavy ſeeds taken out of the ſame fruit, though they grew in the ſame bed, and were cultivated exactly in the ſame manner; nor was their fleſh ſo firm, but rather inclining to be mealy; therefore I would not adviſe the ſowing of theſe light ſeeds, nor thoſe which are very old.

Method of cultivation.—Having thus largely treated of the choice of the ſorts, and of the ſeeds, I ſhall next proceed to the method of cultivating them, in order to obtain plenty of good fruit: the method which I am going to preſcribe being very different from what has been conſtantly practiſed in England, will, I doubt not, be objected to by many; but it is what has been practiſed in all the good gardens in Holland and Germany, where the Cantaleupe Melon is produced in great plenty and perfection; and from ſeveral years experience, I have found this to be the only method in which theſe Melons can be cultivated with ſucceſs; and I am likewiſe convinced of its being the beſt way to obtain plenty of any other ſort of Melon.

It is common to hear many perſons valuing themſelves upon having two or three early Melons, which when brought to the table are not better than a Pumpkin, and theſe are procured at a great expence, and with much trouble; and in order to have them ripe a little earlier than they would naturally come, if ſuffered to grow to their full ſize, the ſtem upon which the fruit grows is commonly twiſted, to prevent the nouriſhment entering the fruit, whereby the growth is checked; then the fruit is cloſely covered with the mowings of graſs-plats, laid of a ſufficient depth to cauſe a fermentation, by which the fruit becomes coloured: but where this unnatural method is practiſed, the fruit has little fleſh, and that has neither moiſture, firmneſs, or flavour; ſo that after four months attendance, with a great expence of dung, &c. there may, perhaps, be three or four brace of Melons produced, which are fitter for the dunghill than the table. Therefore my advice is, never to attempt to have theſe fruit ripe earlier than the middle or latter end of

june, which is generally ſoon enough for this climate; and from that time to the end of ſeptember, they may be had in plenty, if they are ſkilfully managed; and when the autumn has continued favourable, I have had them very good in the middle of october.

Sowing the ſeeds.—But in order to continue this fruit ſo long, the ſeeds muſt be ſown at two or three different ſeaſons: the firſt ſhould be ſown about the middle or end of february, if the ſeaſon proves forward; but if it is otherwiſe, it will be better to defer it till the end of that month; the future ſucceſs greatly depends on the raiſing the plants in ſtrength, which cannot be ſo well effected, if the weather ſhould prove ſo bad after the plants are come up, as that a ſufficient quantity of freſh air cannot be admitted to them, therefore it is not adviſeable to be too early in ſowing the ſeeds.

When the ſeaſon is come, theſe ſeeds may be ſown on the upper ſide of a Cucumber-bed, where there are any; and if there are none, a proper quantity of new horſe-dung muſt be provided, which muſt be thrown in a heap to ferment, and turned over, that it may acquire an equal heat, in the ſame manner as is directed for Cucumbers; and the plants muſt be raiſed and managed in the ſame manner as is directed for them, until they are planted where they are to remain for good, to which article the reader is deſired to turn, to avoid repetition.

The ſecond ſeaſon for ſowing theſe ſeeds is about the middle of march, and both theſe ſowings muſt be underſtood to be planted under frames; for thoſe which are deſigned for bell or hand-glaſſes, or to be covered with oil papers, ſhould not be ſown till about a week in april; for when theſe are ſown earlier, if the plants are properly managed, they will grow ſo long as to extend their ſhoots to the ſides of the glaſſes, before it will be ſafe to let them run out; for it often happens in this country, that we have ſharp morning froſts in the middle of may; ſo that if the ends of theſe Vines are then without the glaſſes, if they are not covered with mats to guard them againſt the froſt, they will be in danger of ſuffering greatly therefrom; and on the other hand, if the plants have ſpread ſo much as to fill the glaſſes, and not permitted to run out, they will be in equal danger of ſuffering by their confinement, from the heat of the ſun in the day time; therefore it is that I ſhould adviſe the putting the ſeed rather a little later into the hot-bed for the glaſſes, than thoſe which are to be covered with the oil papers. Nor will the times here mentioned be found too late, for I have put the ſeeds of Cantaleupe Melons into a hot-bed the third of may, which were not tranſplanted, but remained where they were ſown, and covered with oiled paper; and from this bed I cut a large crop of good fruit, which ripened about the latter end of auguſt, and continued till the end of october. This I only mention, to ſhew what has and may be done, though it muſt not be always depended on.

Preparing the beds or ridges.—But we next come to the making and preparing of the beds, or, as the gardeners term it, the ridges, into which the plants are to be put out to remain; theſe ſhould always be placed in a warm ſituation, where they may be defended from all cold and ſtrong winds, for the eaſt and north winds are generally very troubleſome in the ſpring of the year; ſo that if the place be expoſed to thoſe aſpects, it will be difficult to admit a proper ſhare of freſh air to the young plants; and if it is much expoſed to the ſouth-weſt winds, which often are very boiſterous in ſummer and autumn, theſe will turn up and diſplace the Vines, whereby they will ſuffer greatly; therefore the beſt poſition for theſe beds is where they are open to the ſouth, or a little inclined to the eaſt, and ſheltered at a diſtance by trees from the other points: this place ſhould be incloſed with a good Reed fence, which is better for this purpoſe than any other incloſure, becauſe the winds are deadened by the Reeds, and are not reverberated, as they are by walls, pales, and other cloſe fences; but in making the incloſure, it ſhould be extended to ſuch diſtance every way from the beds, as not to obſtruct the ſun's rays during any part of the day; this ſhould have a door wide enough to admit of wheelbarrows paſſing, to carry in dung, earth, &c. and it ſhould be kept locked, that no perſons ſhould be allowed to go in but thoſe who have buſineſs; for ignorant perſons, having often curioſity to look into the beds, open the glaſſes and let the cold air to the plants, and frequently leave the glaſſes in part open; or ſometimes when they are raiſed by the gardener to admit the freſh air, the tilts are thrown down, ſo that the air is excluded; all which are very injurious to the young plants, as is alſo the handling of the fruit after it is ſet; therefore none ſhould be admitted, but when the perſon who is intruſted with the care of them is there.

Preparation of the earth and dung.—The next thing is the preparation of the earth for theſe plants, in which the Dutch and German gardeners are very exact: the mixture which they generally prepare is of the following ſorts; of hazel loam, one third part; of the ſcouring of ditches or ponds a third part, and of very rotten dung a third part; theſe are mixed up at leaſt one, and often two years, before they make uſe of it, frequently turning it over, to incorporate their parts, and ſweeten it; but the compoſt in which I find theſe plants ſucceed beſt in England, is two-thirds of freſh gentle loam, and one-third of rotten neats dung; if theſe are mixed together one year before it is wanted, ſo as to have the benefit of a winter's froſt and ſummer's heat, obſerving to turn it over often, and never ſuffer weeds to grow upon it, this will be found equal to any other compoſt whatever.

As theſe plants ſucceed beſt when they are planted young, ſo before the plants appear there ſhould be a quantity of new dung thrown in a heap, proportionable to the number of lights intended, allowing about fifteen good wheelbarrows full to each light; this muſt be two or three times turned over, to prepare it (as is directed for Cucumbers) and in a fortnight it will be fit for uſe, at which time the trench muſt be dug to receive the dung, where the bed is intended; this muſt be made wider than the frames, and in length proportional to the number of frames intended. As to the depth, that muſt be according as the ſoil is dry or wet; but in a dry ground it ſhould not be leſs than a foot, or a foot and a half deep; for the lower theſe beds are made, the better they will ſucceed, where there is no danger of their ſuffering by wet. In the well laying and mixing of the dung, the ſame care muſt be taken as is directed for Cucumbers. When the bed is made, the frames ſhould be placed over it to keep out wet; but there ſhould be no earth laid upon it till after it has been three or four days made, and is found of a proper temperature of heat; for many times theſe beds will heat ſo violently when they are firſt made, as to burn the earth, if covered with it; and when this happens, it is much the beſt way to take this earth off again, for the plants will never thrive in it.

Planting and management of the beds.—As ſoon as the bed is found to be of a proper warmth, the earth ſhould be laid upon it, which at firſt need not be more than two inches thick, except in the middle of each light, where the plants are to be placed, where there muſt be a hill raiſed fifteen inches high or more, terminating in a flat cone; in two or three days after the earth is put on the bed, it will be of a proper temper to receive the plants; then in the evening you may tranſplant the plants, but always do it when there is little wind ſtirring: in taking up the plants, their roots ſhould be carefully raiſed with a trowel, ſo as to preſerve all their fibres; for if theſe are broken off, the plants do not ſoon recover this; or if they do, they are generally weaker, and ſeldom make ſo good Vines as thoſe which are more carefully removed: for theſe plants are more nice and tender in tranſplanting than thoſe of Cu-

cumber, eſpecially the Cantaleupe Melon: which, if it is not planted out ſoon after the third (or what the gardeners call the rough) leaf is put out, they are long recovering their vigour; ſo that when it happens that the beds cannot be ready for them in time, it will be a good method to put each plant into a ſmall pot while they are young, and theſe may be plunged into the hot-bed where they were raiſed, or into the Cucumber-bed where there is room, ſo that they may be brought forward; and when the bed is ready, theſe may be turned out of the pots, with the whole ball of earth to their roots, whereby they will receive no check in removing: and this latter method is what I ſhould prefer to any other for the Cantaleupe, becauſe there ſhould never be more than one plant left to grow in each light; therefore in this method there will be no neceſſity of planting more, as there will be no danger of their ſucceeding; whereas in the common way, moſt people plant two or more plants in each light, for fear ſome ſhould miſcarry. When the plants are placed on the top of the hills, they ſhould be gently watered, which ſhould be repeated once or twice after till the plants have taken good root, after which they ſeldom require more; for when they receive too much wet, they often canker at the root, and when that happens they never produce good fruit. When the plants have eſtabliſhed themſelves well in the new beds, there ſhould be a greater quantity of earth laid on the bed, beginning round the hills where the plants grow, that their roots may have room to ſtrike out; and as the earth is put in from time to time, it muſt be trodden or preſſed down as cloſe as poſſible; and it ſhould be raiſed at leaſt a foot and a half thick upon the dung all over the bed, obſerving alſo to raiſe the frames, that the glaſſes may not be too near the plants, leſt the ſun ſhould ſcorch them.

When the plants have got four leaves, the top of the plants ſhould be pinched off with the finger and thumb, but not bruiſed or cut with a knife, becauſe in either of theſe caſes the wound will not ſo ſoon heal over: this pinching is to cauſe the plants to put out lateral branches, for theſe are what will produce the fruit; therefore, when there are two or more of theſe lateral ſhoots produced, they muſt alſo be pinched, to force out more; and this muſt be practiſed often, that there may be a ſupply of what the gardeners call runners, to cover the bed. The management of theſe beds muſt be nearly the ſame as is directed for Cucumbers, therefore I need not repeat it here; but ſhall only obſerve, that the Melons require a greater ſhare of air than Cucumbers, and very little water; and when it is given to them, it ſhould be at a diſtance from their ſtems.

If the plants have ſucceeded well, they will ſpread over the bed, and reach to the frames, in about five or ſix weeks, at which time the alleys between the beds ſhould be dug out; or where there is but one bed, there ſhould be a trench made on each ſide, of about four feet wide, as low as the bottom of the bed, and hot dung wheeled in, to raiſe a lining to the ſame height as the dung of the bed, which ſhould be trodden down cloſe, and afterward covered with the ſame earth as was laid upon the bed, to the thickneſs of a foot and a half or more, treading it down as cloſe as poſſible; this will add to the width of the bed, ſo much as to make it in the whole twelve feet broad, which is abſolutely neceſſary, for the roots of the plants will extend themſelves quite through it; and it is for want of this precaution, that it is common to ſee the Vines of Melons decay, before the fruit is well grown; for where there is no addition made to the width of the bed, the roots will have reached the ſides of the beds by the time that the fruit appears, and having no more room to extend themſelves, their extremities are dried by the ſun and air, which is ſoon diſcovered by the plants hanging their leaves in the heat of the day, and that is ſoon attended with a decay of many of thoſe leaves which are near the ſtem, and the plants from that time gradually languiſh, ſo that the fruit cannot be ſupplied with nouriſhment; but when ripe, will be found to have little fleſh, and that mealy and ill flavoured; whereas thoſe plants which have ſufficient breadth for their roots to run, and the earth laid of a proper depth, and cloſely trod down, will remain in vigour until the froſt deſtroys them, ſo that I have had a ſecond crop of fruit on them, which have ſometimes ripened well; but all the firſt were excellent, and of a larger ſize than theſe ſorts uſually grow: the leaves of theſe plants were very large, and of a ſtrong green, ſo that they were in the utmoſt vigour; whereas in moſt places where the Cantaleupe Melons have been raiſed in England, the beds have been no wider than they were firſt made, and perhaps not more than three inches thickneſs of earth upon them, ſo that the plants have decayed many times without producing a ſingle fruit; and from thence people have imagined, that this ſort of Melon was too tender for this climate, when their ill ſucceſs was entirely owing to their not underſtanding their culture.

There is alſo another advantage attending this method of widening the beds, as above directed, which is that of adding a freſh warmth to the beds, by the hot dung, which is buried on each ſide, which will cauſe the dung in the bed to renew its heat; and as the plants will by this time ſhew their fruit, this additional heat will be of great ſervice in ſetting the fruit, eſpecially if the ſeaſon ſhould prove cold, as it often happens in this country in the month of may. When the beds are made up in the manner here directed, and the Vines have extended ſo far as to fill the frames, and want more room, the frames ſhould be raiſed up with bricks about three inches high, to admit the ſhoots of the Vines to run from under them; for if the plants are ſtrong, they will run ſix or ſeven feet each way from the ſtems; for which reaſon I caution every one to allow them room, and to put but one plant in each light; for when the Vines are crowded, the fruit ſeldom will ſet well, but will drop off when they are as large as an egg; therefore the frames which are deſigned for Melons ſhould not be made ſmall, but rather ſix feet wide; for the wider theſe are, the better will the plants thrive, and produce a greater plenty of fruit.

Pruning and management of the plants.—There is no part of gardening in which the practitioners of this art differ more than in the pruning and managing of theſe plants: nor are there any rules laid down in the ſeveral books in which the culture of Melons has been treated of, by which any perſon can be inſtructed; for there is ſuch inconſiſtency in all their directions, and what is worſe, the greateſt part of them are ſo abſurd, that whoever follows them can never hope to ſucceed; therefore I ſhall, in as few words as poſſible, give ſuch plain directions as I hope will be ſufficient to inſtruct any perſon who is the leaſt converſant in theſe things.

I have before adviſed the pinching off the ends of the plants as ſoon as they have a joint, in order to get lateral ſhoots, which are by the gardeners called runners; and when theſe ſhoots have two or three joints, to pinch off their tops to force out more runners, becauſe it is from theſe that the fruit is to be produced; but after a ſufficient number are put out, they ſhould not be ſtopped again, but wait for the appearance of the fruit, which will ſoon come out in plenty; at which time the Vines ſhould be carefully looked over three times a week, to obſerve the fruit, and make choice of one upon each runner, which is ſituated neareſt the ſtem, having the largeſt foot-ſtalk, and that appears to be the ſtrongeſt fruit, and then pinch off all the other fruit which may appear on the ſame runner: alſo pinch off the end of the runner at the third joint above the fruit, and if the runner is gently pinched at the next joint above the fruit, it will ſtop the ſap, and ſet the fruit. There is alſo another method practiſed by ſome gardeners to ſet this fruit, which is the taking off ſome of the male flowers, whoſe farina are juſt

ripe

ripe and fit for the purpoſe, laying them over the female flowers, which are ſituated on the crown of the young fruit, and with their nails gently ſtrike the male flowers to ſhake the farina into the female flowers, whereby they are impregnated, and the fruit ſoon after will ſwell, and ſhew viſible ſigns of their being perfectly ſet; where the plants are under frames, and the wind excluded from them, which is neceſſary to convey the farina from the male to the female flowers, this practice may be very neceſſary. The taking off all the other fruit will prevent the nouriſhment being drawn away from the fruit intended to grow, which, if they were all left on the plant, could not be ſupplied with ſufficient nouriſhment; ſo that when they come to be as large as the end of a man's thumb, they frequently drop off, and ſcarce one of them ſets, which will be prevented by the method before directed: but there are ſome perſons, who are ſo covetous of having a number of fruit, as not to ſuffer any to be taken off, whereby they generally fail in their expectation. My allowing but one fruit to be left upon each runner is, becauſe if half theſe ſtand there will be full as many fruit as the plant can nouriſh; for if there are more than eight upon one plant, the fruit will be ſmall, and not ſo well nouriſhed: indeed I have ſometimes ſeen fifteen or twenty Melons upon one plant, but theſe have generally been of the ſmaller kinds, which do not require ſo much nouriſhment as the Cantaleupes, whoſe ſkins are of a thick ſubſtance; ſo that where a greater number are left of them than the plants can well ſupply, their fleſh will be remarkably thin.

As I before adviſed the ſtopping or pinching off the runners three joints above the fruit, ſo by this there will be freſh runners produced a little below the places where the others were pinched; therefore it is that I adviſe the careful looking over the Vines ſo often, to ſtop theſe new runners ſoon after they come out, as alſo to pull off the young fruit which will appear; and this muſt be repeated as often as is found neceſſary, which will be until thoſe intended to ſtand are grown ſo large as to draw all the nouriſhment which the plants can ſupply, for then the plants will begin to abate of their vigour. Theſe few directions, if properly made uſe of, is all the pruning which is neceſſary to be given them; but at the ſame time when this is practiſed, it may be neceſſary to give ſome water to the plants, but at a diſtance from their ſtems, which will be of ſervice to ſet the fruit, and cauſe it to ſwell, but this muſt be done with great caution.

The glaſſes of the hot-bed ſhould alſo be raiſed high, to admit a large ſhare of air to the plants, otherwiſe the fruit will not ſet; and if the ſeaſon ſhould prove very warm, the glaſſes may be frequently drawn off, eſpecially in an evening, to receive the dews, provided there is but little wind ſtirring; but the glaſſes ſhould not remain off the whole night, leſt the cold ſhould prove too great; but in warm weather, the glaſſes may be kept off from ten in the morning till evening.

When the plants have extended themſelves from under the frames, if the weather ſhould alter to cold, it will be neceſſary to cover their extremities every night with mats; for if theſe ſhoots are injured, it will retard the growth of the fruit, and often proves very injurious to the plants: and now what water is given to the plants, ſhould be in the alleys between the beds; for as the roots of the Vines will by this time have extended themſelves through the alleys, ſo when the ground there is well moiſtened, the plants will receive the benefit of it; and by this method, the ſtems of the plants will be preſerved dry, whereby they will continue ſound; but theſe waterings ſhould not be repeated oftener than once a week in very dry warm weather, and be ſure to give as much air as poſſible to the plants when the ſeaſon is warm.

Culture under hand or bell-glaſſes.—Having given full inſtructions for the management of thoſe Melons which are raiſed under frames, I ſhall next proceed to treat of thoſe which are raiſed under bell or hand-glaſſes. The plants for theſe muſt be raiſed in the ſame manner as has been already directed, and about the latter end of april, if the ſeaſon proves forward, will be a good time to make the beds; therefore a ſufficient quantity of hot dung ſhould be provided, in proportion to the intended number of glaſſes, allowing ſix or eight good wheelbarrows of dung to each glaſs. Where there is but one bed, which is propoſed to be extended in length, the trench ſhould be dug out four feet and a half wide, and the length according to the number of glaſſes, which ſhould not be placed nearer than four feet; for when the plants are too near each other, the Vines will intermix, and fill the bed ſo cloſely as to prevent the fruit from ſetting: in digging the trench, it ſhould be ſo ſituated as to allow for the widening of the bed three or four feet on each ſide; the depth muſt be according as the ſoil is dry or wet; but, as was before obſerved, if the ſoil is ſo dry as that there is no danger of the beds being hurt by the wet, the lower they are made in the ground the better: in the making of the beds, the ſame regard muſt be had to the well mixing and laying of the dung as was before directed; and after the dung is laid, there ſhould be a hill of earth raiſed, where each plant is to ſtand, one foot and a half high; the other part of the bed need not as yet be covered more than four inches thick, which will be ſufficient to keep the warmth of the dung from evaporating; then the glaſſes ſhould be placed over the hills, and ſet down cloſe, in order to warm the earth of the hills to receive the plants; and if the beds work kindly, they will be in a proper temperature to receive the plants in two or three days after making; then the plants ſhould be removed, in the ſame manner as was before directed; and if they are in pots, ſo that there will be no danger of their growing, there ſhould but one plant be put under each glaſs; and if they are not in pots, there ſhould be two, one of which may be afterward taken away, if they both grow. Theſe plants muſt be watered at firſt planting, to ſettle the earth to their roots, and ſhaded every day until they have taken new root; and if the nights prove cold, it will be proper to cover the glaſſes with mats, to preſerve the warmth of the bed.

Where there are ſeveral of the beds intended, they ſhould be placed at eight feet diſtance from each other, that there may be a proper ſpace left between them, to be afterward filled up, for the root of the Vines to have room for extending themſelves, for the reaſons before given.

When the plants have taken good root in the beds, their tops muſt be pinched off; and their pruning, &c. muſt, from time to time, be the ſame as for thoſe under the frames. In the day time, when the weather is warm, the glaſſes ſhould be raiſed on the oppoſite ſide to the wind, to admit freſh air to the plants; for where this is not obſerved, they will draw up weak and ſickly, therefore all poſſible care ſhould be taken to prevent this; for if the runners have not proper ſtrength, they can never ſupply the fruit with nouriſhment.

When the plants are grown ſo long as to reach the ſides of the glaſſes, if the weather proves favourable, the glaſſes muſt be ſet on three bricks, ſo as to raiſe them about two inches from the ſurface of the beds, to give room for the Vines to run out from under them; but when this is done, the beds ſhould be covered all over with earth to the depth of one foot and a half, and trod down as cloſe as poſſible; and if the nights ſhould prove cold, there ſhould be a covering of mats put over the beds, to prevent the cold from injuring the tender ſhoots of the Vines; but as the Vines of the Cantaleupe Melons are impatient of wet, it will be neceſſary to arch the beds over with hoops to ſupport the mats, that they may be ready for covering at all times when they require it; which is the only ſure method to have theſe Melons ſucceed in England, where the weather is ſo very uncertain and variable; for I have

have had ſome beds of theſe Melons in as fine order under theſe glaſſes as could be deſired, which were totally deſtroyed by one day's heavy rain in june.

After the thickneſs of earth is laid upon the beds, if the weather ſhould prove cold, it will be adviſeable to dig trenches on each ſide of the beds, into which you ſhould lay a ſufficient quantity of hot dung, to make it of the ſame thickneſs with the bed, after the manner before directed for the frames; or if there is a ſufficient quantity of hot dung ready, the whole ſpace between the beds may be dug out and filled up with the dung, laying thereon the earth a foot and a half deep, treading it down cloſe; this new dung will add a freſh warmth to the beds, and cauſe the plants to ſhew fruit ſoon after.

The watering of theſe plants muſt be done with great caution, and not given to their ſtems; the pinching off the runners muſt alſo be duly attended to, as alſo the pulling off all ſuperfluous fruit, to encourage thoſe which are deſigned to remain: and in ſhort, every thing before directed for thoſe under frames, muſt likewiſe be obſerved for theſe; and the further care is, to cover them in all hard rains and cold nights, with mats, which, if performed with care, there will be little danger of their miſcarrying, and theſe Vines will remain vigorous until the cold in autumn deſtroys them.

Raiſing under paper frames.—There have been many perſons, who of late years have raiſed their Melons under oiled paper, and in many places they have ſucceeded well; but where this is practiſed, there muſt be great care taken not to keep theſe coverings too cloſe over them; for where that is done, the Vines will draw very weak, and rarely ſet their fruit in any plenty; therefore where theſe coverings are propoſed to be uſed, I ſhould adviſe the bringing up of the plants under hand or bell-glaſſes, in the manner before directed, until they are grown far enough to be let out from under the glaſſes; and then, inſtead of the covering with mats, to put over the oiled paper; and if this covering is prudently managed, it will be the beſt that can be uſed. The beſt ſort of paper for this purpoſe is that which is ſtrong, and not of too dark a colour; and it ſhould be done over with linſeed oil, which will dry ſoon. There ſhould be a proportionable number of ſheets of this paper paſted together, as will ſpread to the dimenſions of the frame to which it is faſtened; and if this is fixed to the frame before the oil is rubbed over it, ſo much the better; but this ſhould be done ſo long before they are uſed, as that the oil may be thoroughly dry, and the ſtench gone off, otherwiſe it will deſtroy the plants.

There are ſome perſons who make theſe frames of broad hoops, in imitation of the covers of waggons; but as theſe are cumberſome to move, and there are no conveniencies for admitting air to the plants, but by raiſing the whole frame on one ſide, I prefer thoſe made of pantile laths, framed like the ridge of a houſe; and each ſlope having hinges, may be raiſed at pleaſure to admit the air to the plants.

Management after the fruit is ſet.—The further management of the Melons, after their fruit is ſet, is to keep pulling off all the ſuperfluous fruit, and to pinch off all weak runners, which may draw away part of the nouriſhment from the fruit; as alſo to turn the fruit gently twice a week, that each ſide may have equal benefit of the ſun and air; for when they are ſuffered to lie with the ſame ſide conſtantly to the ground, that ſide will become of a pale or whitiſh colour, as if it were blanched, for want of theſe advantages. The plants will require a little water in very dry weather, but this ſhould be given them in the alleys at a diſtance from the ſtems of the plants, and not oftener than once in a week or ten days, at which time the ground ſhould be well ſoaked in the alleys. This will encourage the growth of the fruit, and cauſe the fleſh to be thick; but the great caution which is neceſſary to be obſerved, is not to over-water the plants, which is certain injury to them: alſo be ſure to give as much free air as poſſible, at all times, when the weather will permit, for this is abſolutely neceſſary to render the fruit good.

Time of cutting.—When the fruit is fully grown, they muſt be duly watched to cut them at a proper time; for if they are left a few hours too long upon the Vines, they will loſe much of their delicacy, therefore they ſhould be looked over at leaſt twice every day; and if thoſe fruit which are intended for the table, are cut early in the morning, before the ſun has warmed them, they will be much better flavoured; but if any ſhould require to be cut afterward, they ſhould be put into cold ſpring water, or ice, to cool them, before they are brought to the table: and thoſe cut in the morning, ſhould be kept in the cooleſt place till they are ſerved up to table. The ſign of this fruit's maturity is, that of its beginning to crack near the foot-ſtalk, and its beginning to ſmell, which never fail; for as theſe Cantaleupe Melons ſeldom change their colour until they are too ripe, that ſhould never be waited for. The directions here given for the management of the Cantaleupe Melons, will be found equally good for all the other ſorts, as I have fully experienced; for in the common method of managing them, where the earth is laid but three or four inches thick, the plants are very apt to decay before the fruit is ripe; for their roots ſoon reach the dung, and are extended to the ſides of the bed, where their tender fibres are expoſed to the air and ſun, which cauſe the leaves of the plants to hang down in the heat of the day, ſo it is neceſſary to ſhade them with mats, to prevent their decay: and this alſo occaſions the watering of the plants often to keep them alive, which is alſo prejudicial to their roots; whereas when the beds are made of a proper width, and earthed of a ſufficient thickneſs, the plants will bear the ſtrongeſt heat of the ſun in this climate, without ſhewing the leaſt want of moiſture, or their leaves drooping, and they will continue in health till the autumn cold deſtroys them.

In ſaving of the ſeeds I repeat here, that only ſuch ſhould be regarded which are taken from the firmeſt fruit, and thoſe which have the higheſt flavour; and if theſe are taken out with the pulp entire, without diſplacing the ſeeds, and ſuffered to remain in the pulp two or three days before it is waſhed out, the better; and then to preſerve only the heavy ſeeds, which ſink in water.

[*Additional directions for the culture and management of Melons.*

1. If you are obliged to uſe new ſeed, hang it up in a paper or phial in a dry room near the fire all winter, or in a window expoſed to the ſun, or carry it in your pocket three or four weeks. If your ſeed be too old, ſteep it two or three hours in milk lukewarm, immediately before you ſow it.

2. A ſmall family cannot have leſs than one three-light frame for the early crop, and three-hand or bell-glaſſes, or three holes under oiled paper, for the late crop; which will produce only from thirty to forty Melons. A middling family will require double this quantity. And a large family ſhould have four three-light frames, and twelve glaſſes or holes under oiled paper, to inſure a tolerable ſupply of fruit during the ſeaſon.

3. In the nurſery bed the ſeedling plants ſhould be gradually earthed up as they riſe in height. When the two or three firſt rough leaves are fully expanded, and another is forming in the centre, appearing like a bud, this latter ſhould be pinched off cloſe to the ſecond or third leaf, to procure lateral ſhoots or runners: and when theſe firſt runners appear, the plants are ready for tranſplanting into the fruiting hot-bed. This will be in five or ſix weeks from the time of ſowing.

4. Many perſons prefer making the hot-beds entirely on the ſurface, for the ſake of lining them more completely with hot dung, to renew the heat when wanted. The height of the bed ſhould be three feet and a half, or four feet, the back or north ſide being raiſed three or four inches higher. The

frames being put on to keep out the wet, and draw up the heat, the glaſſes ſhould be kept up behind, that the ſteam may paſs away; and the great heat will not be ſufficiently abated for moulding the bed till a week at leaſt, or perhaps ten or fifteen days, according to the ſubſtance of the bed.

5. A buſhel of mould is the proper quantity for forming the hill in which the young fruiting plant is to be ſet; the height may be about fifteen inches: ſo that the plant may at the ſame time be near the glaſs, to enjoy the full benefit of the ſun, and have a ſufficient depth of earth for the roots to ſpread in. Having ſpread a layer of earth three inches thick over the other parts of the bed to keep down the ſteam of the dung, cloſe the lights, and when the earth is warm put in the plants. This will be in a day or two. If then the mould appear to be too dry, give a little water towards the outſide, without wetting the plants much. Shut the lights to draw up the heat about the roots, but raiſe them again afterwards to let out the ſteam.

6. Freſh air ſhould be admitted at every opportunity in calm warm weather, by ſetting up the lights behind from half an inch to two, three and four inches high, according to the quantity of ſteam in the bed, and the temperature of the outward air. At firſt, this muſt ſometimes be done in the evening, when the ſteam is very abundant. Some perſons uſe a contrivance of leaden or tin bent pipes, communicating with the open air, and paſſing through the body of dung, to introduce warm air into the frames, when the weather will not admit of the lights being opened. At night the glaſſes muſt be covered with a ſingle or double mat, according to the ſeaſon, being careful that the mats do not hang over the ſides of the frame and bed, which by drawing up the ſteam and excluding the air too much, will cauſe the plants to become weak and yellow. Water occaſionally when the earth is dry: but all agree that Melons can hardly have too little water, that the Vines ſhould never be wetted at firſt, and that little or no water ſhould be given when the fruit is nearly full grown. If the earth be loamy, preſſed down cloſe, and not leſs than twelve or fifteen inches deep, the plants, after two or three waterings to ſettle their roots, will require very little more water afterwards: but if the earth be light, and of a leſs depth, occaſional waterings will be requiſite in warm weather; obſerving that the water be ſoft and not cold, and that it be not given while the fruit is ſetting, till it is of the ſize of a large walnut.

7. The firſt danger to the plants will be from over-heating. In this caſe, remove ſome of the earth from the lower part of the hill, and if it be burned, put ſome freſh earth in its place; and when the burning ſubſides, replace the removed mould on the hill.

This danger being over in a few days or a week, the heat muſt then be retained as much as poſſible, by laying dry long litter round the ſides of the bed. And when the heat declines conſiderably, it muſt be revived by a ſubſtantial lining of hot dung as above directed: at the ſame time laying on freſh earth to keep the rancid ſteam of the hot dung from injuring the plants. As the fibres of the plants advance, freſh warm mould muſt be added gradually round the hills, till it is within an inch of the ſame height with them.

8. When the vines have advanced to ſome length, diſpoſe them regularly, and ſpread ſome dry clean reeds over the beds thinly, for the vines to run upon; this is better than covering the whole bed cloſely with flat tiles, as is practiſed by ſome. As the fruit ſets, lay a piece of tile under each, and as it advances towards maturity, raiſe it on a brick to enjoy more of the ſun and air, and turn it every three days.

9. The ſize and flavour of the fruit will depend much upon keeping up what is called a bottom heat, which is done by occaſional linings of dung, ſo late as the end of april, and the beginning and middle of may. The plants ſhould be occaſionally ſhaded in very hot days, when there is danger of their leaves being ſcorched by the ſun. When the leaves preſs againſt the glaſſes, the frame may be raiſed at bottom three inches; and if they are much crowded, they may be thinned in proportion, ſo as to admit the fruit to the full benefit of the ſun and air. When the fruit is ſet and advanced, if the vines are over-crowded, ſmall runners and luxuriant ſhoots may be cut off quite cloſe, to encourage the free growth, and increaſe the ſize of the Melons. In june the vines filling the frames, may be confined by pruning, or may be ſuffered to run out on the top of the lining to produce ſome late fruit, by raiſing up the frame for that purpoſe.

10. The Melon will proſper in any rich pliable kitchen-garden earth, prepared ſome months in a heap; but it does beſt in a fine mellow loam, ſuch as Mr. Miller calls hazel loam, from the ſurface of a paſture or common, with one third of rotten neat's dung, or old hot-beds. Others prefer a ſtronger ſoil, compoſed of neat's dung, virgin earth, and yellow fat marl, in equal proportions. Others again recommend the earth and dung to be reduced to a proper degree of lightneſs by coal aſhes ſifted fine; and the compoſt to be frequently wetted with fat pot-liquor and ſoap-ſuds; then laid in a ridge to dry, and about Chriſtmas mixed with ſome quick lime in powder. Some direct the compoſt to be riddled very fine; whilſt others forbid it to be ſifted or ſereened, and will have it only broken with the ſpade.

11. Some perſons are very nice about their water. Rain water is certainly to be preferred, and if hard water only can be had, it ſhould ſtand in the air ſome time in an open veſſel. It is a common practice to ſet bottles of water into the frames a day before it is to be uſed, to water the young plants, which require no great quantity. Some medicate the water with ſheep's-dung, or good rotten horſe-dung, and wood aſhes, and put a lump of ſal-ammoniac into the bottle when they water the ſeedling plants. But of ſuch niceties there is no end.

12. Cut the fruit in a morning, before the ſun ſhines hot upon it, with all its ſtalk to it, and lay it in a dry, cool, airy place, till it is wanted for table. If it is to be ſent to a diſtance, cut it two or three days before it is perfectly ripe.

13. Bark hot-beds are ſometimes uſed in the culture of Melons, for the fruiting beds, and are eſteemed for this purpoſe as well as others, on account of their regular and durable heat.

The expenſe, indeed, of theſe is ſomewhat greater, but the trouble is leſs, and fruit may be produced to greater advantage, for no lining or very little will be neceſſary, nor is ſo much danger to be apprehended from ſteaming or over-heating as in dung hot-beds. Theſe bark-beds muſt be made either in a brick pit, or in a frame of ſtrong oak or barge ſtanking.

14. Melons may be raiſed with ſucceſs from cuttings, and fruit may be obtained this way rather ſooner than by plants raiſed from ſeed.

8. This, with ſome of the other ſorts, is rarely cultivated, except in botanic gardens, for the ſake of variety; the plants being tender, and the fruit very indifferent. This rambles very far, and therefore requires much room.

9. The Cucumber.

Culture of early Cucumbers.—Thoſe perſons who are very deſirous to be early with their Cucumbers, generally ſow their ſeeds before Chriſtmas, but the generality of gardeners commonly put their ſeeds into the hot-bed about Chriſtmas. Where perſons have the conveniency of a ſtove for raiſing theſe plants, it is attended with leſs trouble than a common hot-bed, and is a much ſurer method, becauſe the plants will have a much greater ſhare of air, which will alſo be leſs mixed with damp or rancid vapours; for by the heat of the fires theſe will be diſſipated, and the temperature of the air is kept more equal than can be done with all poſſible care in a hot-bed, at a ſeaſon when we enjoy but little

ſun; therefore where there is this convenience, the ſeeds ſhould be ſown in ſmall pots, filled with light dry earth, and plunged into the tan-bed, in the warmeſt part of the ſtove. The pots with earth ſhould be plunged three or four days before the ſeeds are ſown, that the earth may be properly warmed to receive them; the ſeed ſhould be at leaſt three or four years old, but if it is more, provided it will grow, it will be the better. If the ſeeds are good, the plants will begin to appear in about a week or nine days, at which time there muſt be as many halfpenny pots filled with dry light earth as there are plants deſigned for planting, always allowing for loſs; ſo that where twenty-four plants are wanting, there ſhould be thirty raiſed; theſe pots ſhould be plunged into the bark-bed, that the earth may be warmed to receive the plants, which ſhould be pricked into theſe pots as ſoon as the two firſt leaves are raiſed above ground; into each of theſe pots may be two plants pricked, but when they have taken root, and are ſafe, the worſt ſhould be drawn out, being careful not to diſturb the roots of thoſe which are left. In the management of theſe plants, there muſt be great care taken not to give them too much water; and it will be very proper to put the water into the ſtove ſome hours before it is uſed, that the cold may be taken off; but there muſt be caution uſed not to make it too warm, for that will deſtroy the plants; they muſt alſo be guarded from the moiſture which frequently drops from the glaſſes of the ſtove, which is very deſtructive to theſe plants while young. As theſe plants muſt not be kept too long in the ſtove left they become troubleſome to the other plants, there ſhould be a proper quantity of new dung prepared for making a hot-bed to receive them; this muſt be in proportion to the quantity of holes or plants intended: for a middling family ſix or nine lights of Cucumbers will be ſufficient, and for a large one double the quantity; but the beds where they are deſigned to remain need not be made ſo ſoon, but rather a ſmall bed of one light, in which the plants may be trained up till they have acquired a greater ſhare of ſtrength; and for this bed one good cart load of dung will be ſufficient. This ſhould be new, and not too full of ſtraw, nor ſhould it want a proper portion; it ſhould be well mixed together and thrown in a heap, mixing ſome ſea-coal aſhes with it; after it has lain in a heap a few days, and has fermented, it ſhould be carefully turned over and mixed, laying it up again in a heap; and if there is a great ſhare of ſtraw in it, there may be a neceſſity for turning it over a third time, after having laid a few days: this will rot the ſtraw and mix it thoroughly with the dung, ſo there will be leſs danger of its burning afterward when the bed is made, which ſhould be done when the dung is in proper order. The place where the hot-bed is made ſhould be well ſheltered by Reed hedges, and the ground ſhould be dry; then there ſhould be a trench made in the ground, of a proper length and breadth, and a foot deep at leaſt; into which the dung ſhould be wheeled and carefully ſtirred up and mixed, ſo that no part of it ſhould be left unſeparated, for where there is not this care taken, the bed will ſettle unequally; there ſhould alſo be great care taken to beat the dung down cloſe in every part of the bed alike. *When the bed is made, the frame and glaſſes ſhould be put upon it to keep out the rain, but there ſhould be no earth laid upon the dung till two or three days after, that the ſteam of the dung may have time to evaporate. If there ſhould be any danger of the bed burning, it will be proper to lay ſome ſhort old dung, or ſome neats dung, over the top of the hot dung about two inches thick, which will keep down the heat, and prevent the earth from being burnt; after this there ſhould be a ſufficient number of three farthing pots placed upon the bed, filled with light dry earth, and all the interſtices between them filled up with any common earth. In two or three days the earth in theſe pots will be of a proper temperature of warmth to receive the plants, which ſhould be then turned out of the halfpenny pots, preſerving the ball of earth to their roots, and planted into the three farthing pots, filling up the pots with good earth; then a little water ſhould be given them to ſettle the earth about their roots, being careful not to give them too much wet; and as theſe will have ſuch large balls of earth to their roots, they will not feel their removal, therefore will not require ſhading from the ſun; but the glaſſes ſhould be raiſed up a little on the contrary ſide from the wind, to let the ſteam of the bed paſs off; and they ſhould alſo be frequently turned in the day-time, that the wet occaſioned by the ſteam of the dung may be dried, otherwiſe the moiſture will fall on the plants, which will be very injurious to them. If the bed ſhould heat too violently, ſo as to endanger ſcalding the roots of the plants, the pots may be raiſed ſo as to allow of a little hollow at their bottoms, which will effectually prevent injury thereby; and when the heat declines, the pots may be ſettled down again. The glaſſes of the hot-bed ſhould be well covered with mats every night, to keep the bed in a proper temperature of heat, and great care muſt be taken to admit freſh air every day to the plants; but this ſhould be done with caution, ſo as to guard againſt the cold winds which uſually blow at that ſeaſon; ſo that a mat or canvaſs ſhould be hung over the opening made by raiſing of the glaſſes, to prevent the cold air from ruſhing in too violently, and the glaſſes ſhould always be raiſed on that ſide which is contrary to the wind. The plants will alſo require to be frequently watered, but it muſt be cautiouſly given them at this ſeaſon, and the water ſhould not be cold, but either placed in a ſtove, or put into a warm heap of dung, to take off the chill from it before it is uſed.

If the weather ſhould prove bad, and the heat of the bed decline, there ſhould be ſome hot dung laid round the ſides of the bed to renew the heat, which muſt not be ſuffered to fail; for as the plants have been tenderly brought up, they muſt not ſuffer from cold, for that will ſoon deſtroy them.

In this bed the plants may remain about three weeks or a month, in which time, if they have been properly managed, they will have obtained ſufficient ſtrength to put out for good; therefore a proper quantity of dung ſhould have been mixed and turned ready for making the beds. The uſual quantity allowed at this ſeaſon, is one good cart load to each light: this ſhould be well mixed and turned over in the manner before directed; then a trench ſhould be dug in the ground the length and width of the intended bed, into which the dung ſhould be wheeled, and properly worked according to the above directions, and ſome old dung or neats dung ſpread over the top. The frames and glaſſes ſhould then be put on the bed, which ſhould be raiſed every day to let the ſteam of the dung paſs off, and in about three days the bed will be in a proper temperature of heat to receive the plants; at which time the dung ſhould be covered over with dry earth about four inches thick, and in the middle of the bed it ſhould be three or four inches thicker; this ſhould be laid upon the dung at leaſt twenty-four hours before the plants are removed into the bed, that the earth may be properly warmed; then the plants ſhould be carefully ſhaken out of the pots, preſerving all the earth to their roots, and placed on the top of the earth in the middle of the bed. Two, or at moſt three of theſe plants will be ſufficient for each light, and theſe ſhould be placed at about ſeven or eight inches aſunder, not all the roots together, as is too often practiſed. When the plants are thus ſituated in the bed, the earth which was laid ſo much thicker in the middle of the bed, ſhould be drawn up round the ball which remained to the roots of the plants, into which their roots will ſoon ſtrike; there ſhould always be a magazine of good earth laid under cover to keep it dry, for the earthing of theſe beds; for if it is taken up wet, it will chill the beds, and alſo occaſion great dumps therein,

therein, therefore it is quite neceſſary to have a ſufficient quantity of earth prepared long before it is uſed. When the plants are thus ſettled, they muſt have proper air and water, according as they may require, being careful not to admit too much cold air, or give too much water; the glaſſes ſhould alſo be well covered with mats every night, to keep up the warmth of the bed, and ſome freſh earth ſhould be put into the bed at different times, which ſhould be laid at ſome diſtance from the roots of the plants till it is warmed, and then ſhould be drawn up round the heap of the earth in which the plants grow, to increaſe the depth; this ſhould be raiſed to the full height of the former ball, that the roots of the plants may more eaſily ſtrike into it: by this method of ſupplying the earth, the whole ſurface of the beds will be covered nine or ten inches with earth, which will be of great ſervice to the roots of the plants; for where the earth is very ſhallow, the leaves of the plants will always hang in the heat of the day, unleſs they are ſhaded, and the plants will require more water to keep them alive, than is proper to give them: therefore it will be found much the better way to allow a proper depth of earth to the beds: but the reaſon of not laying the quantity of earth on the bed when it is firſt made, is, that the dung ſhould not be too much chilled by it, or that the earth may not be burned, which might be endangered thereby, were the whole thickneſs to be laid on at once; beſides, by thus gradually applying the earth, it will be freſh, and much better for the roots of the plants, than that which has been long upon the bed, and has been too much moiſtened by the ſteam ariſing from the dung.

If the heat of the bed ſhould decline, there ſhould be ſome hot dung laid round the ſide of the bed to renew the heat; for if that ſhould fail at the time when the fruit appears, they will fall off and periſh, therefore this muſt be carefully regarded; and when the plants have put out ſide branches, which the gardeners call runners, they ſhould be properly placed, and pegged down with ſmall forked ſticks to prevent their riſing up to the glaſſes, and alſo from croſſing and entangling with each other; for when they are properly directed at firſt, there will be no neceſſity for twiſting and tumbling the plants afterwards, which is always hurtful to them.

When the earth of the bed is laid the full thickneſs, it will be neceſſary to raiſe the frames, otherwiſe the glaſſes will be too cloſe to the plants; but when this is done, there muſt be care taken to ſtop the earth very cloſe round the ſide of the frame, to prevent the cold air from entering under them. The watering the plants, and admitting freſh air to them, muſt be diligently attended to, otherwiſe the plants will be ſoon deſtroyed; for a little neglect either of admitting air, or letting in too much, or of over watering, or ſtarving the plants, will very ſoon deſtroy them paſt recovery.

When the fruit appears upon the plants, there will alſo appear many male flowers on different parts of the plant; theſe may at firſt ſight be diſtinguiſhed, for the female flowers have the young fruit ſituated under the flowers, but the male have none; but theſe have three ſtamens in their centre with their anthers, which are loaded with a golden powder. This is deſigned to impregnate the female flowers, and when the plants are fully expoſed to the open air, the ſoft breezes of wind convey this farina or male powder from the male to the female flowers; but in the frames where the air is frequently too much excluded at this ſeaſon, the fruit often drops off for want of it; and I have often obſerved, that bees that have crept into the frames when the glaſſes have been raiſed to admit the air, have ſupplied the want of thoſe gentle breezes of wind, by carrying the farina of the male flowers on their hind legs into the female flowers, where a ſufficient quantity of it has been left to impregnate them. Theſe inſects therefore have taught the gardeners a method to ſupply the want of free air, which is ſo neceſſary for the performance of this in the natural way. This is done by carefully gathering the male flowers at the time when this farina is fully formed, and carrying them to the female flowers, turning them down over them, and with the nail of one finger, gently ſtriking the outſide of the male, ſo as to cauſe the powder on the ſummits to ſcatter into the female flowers, and this is found to be ſufficient to impregnate them; ſo that by practiſing this method, the gardeners have now arrived at a much greater certainty than formerly, to procure an early crop of Cucumbers and Melons.

When the fruit of the Cucumbers are thus fairly ſet, if the bed is of a proper temperature of warmth, they will ſoon ſwell, and become fit for uſe; ſo all that is neceſſary to be obſerved, is to water the plants properly, which ſhould be done by ſprinkling the water all over the bed, for the roots of the plants will extend themſelves to the ſide of the bed; therefore thoſe who are inclined to continue theſe plants as long as poſſible in vigour, ſhould add a ſufficient thickneſs of dung and earth all round the ſides of the beds, ſo as to enlarge them to near double their firſt width; this will ſupply nouriſhment to the roots of the plants, whereby they may be continued fruitful great part of the ſummer; whereas, when this is not practiſed, the roots of the plants, when they have reached the ſide of the beds, are dried by the wind and ſun, ſo that the plants languiſh and decay long before their time.

Thoſe gardeners who are fond of producing early Cucumbers, generally leave two or three of their early fruit, which are ſituated upon the main ſtem of the plant near the root, for ſeed; which, when fully ripe, they carefully ſave to a proper age for ſowing, and by this method they find a great improvement is made of the ſeed; and this they always uſe for their early crops only, for the ſucceeding crops do not deſerve ſo much care and attention.

I have here only mentioned the method of raiſing the young Cucumber plants in ſtoves; for as theſe conveniencies are now pretty generally made in the curious kitchen-gardens in moſt parts of England, this method may be more univerſally practiſed; but in ſuch gardens where there are no ſtoves, the ſeeds ſhould be ſown upon a well prepared hot-bed: and here it will be the beſt way to ſow the ſeeds in ſmall halfpenny pots, becauſe theſe may be eaſily removed from one bed to another, if the heat ſhould decline; or, on the contrary, if the heat ſhould be too great, the pots may be raiſed up, which will prevent the ſeed or the young plants from being injured thereby. When the plants are come up as was before directed, there ſhould be a freſh hot-bed prepared, with a ſufficient number of halfpenny pots plunged therein ready to receive the plants, which muſt be planted into them in the ſame manner as was before directed, and the after-management of the plants muſt be nearly the ſame; but as the ſteam of the hot-bed frequently occaſions great damps, there muſt be great care to turn and wipe the glaſſes frequently, to prevent the condenſed moiſture falling on the plants, which is very deſtructive to them. There muſt alſo be great attention to the admitting freſh air at all proper times, as alſo to be careful in keeping the bed to a proper temperature of heat; for as there is a want of fire to warm the air, that muſt be ſupplied by the heat of dung: afterwards theſe plants muſt be ridged out in the ſame manner as before directed.

If the bed is of a good temper for heat, your plants will take root in leſs than twenty-four hours; after which time you muſt be careful to let in a little air at ſuch times when the weather will permit, as alſo to turn the glaſſes upſide down every day to dry; for the ſteam of the bed condenſing on the glaſſes, will fall down upon the plants, and be very injurious to them: therefore whenever the weather is ſo bad as not to permit the glaſſes to lie turned long, you ſhould at leaſt turn them once or twice a day, and wipe off the moiſture with a woollen cloth; but you muſt alſo be very careful how you let in too much cold air, which is equally deſtructive to the

tender

tender plants; therefore, to avoid this, it is a very good method to faſten before the upper ſide of the frame, where the air is ſuffered to enter the bed, a piece of coarſe cloth or mat, ſo that the air which enters may paſs through that, which will render it leſs injurious to your plants.

You muſt alſo be very cautious in giving water to the plants while young; and whenever this is done, it ſhould be ſparingly, and the water ſhould be placed either in a heap of dung, or in ſome other warm place, for ſome time before it is uſed, ſo as to be nearly of a temperature for warmth with the inclоſed air of the hot-bed; and as the plants advance in height, you ſhould have a little dry ſifted earth always ready to earth up their ſhanks, which will greatly ſtrengthen them. You muſt alſo be very careful to keep up the heat of the bed, which, if you ſhould find decline, you muſt lay a little freſh litter round about the ſides of the bed, and alſo keep the glaſſes well covered in the nights or in bad weather: but if, on the other hand, your bed ſhould prove too hot, you ſhould thruſt a large ſtake into the ſide of the dung in two or three places, almoſt to the middle of the bed, which will make large holes, through which the greateſt part of the ſteam will paſs off without aſcending to the top of the bed; and when you find it has anſwered your purpoſe by ſlacking the heat of your bed, you muſt ſtop them up again with dung.

Theſe directions, if carefully attended to, will be ſufficient for raiſing the plants in the firſt bed: you muſt therefore, when you perceive the third, or rough leaf begin to appear, prepare another heap of freſh dung, which ſhould be mixed with aſhes, as was before directed; this ſhould be in quantity according to the number of holes you intend to make. The common allowance for ridging out the earlieſt plants is, one load to each light or hole, ſo that the bed will be near three feet thick in dung; but for ſuch as are not ridged out till march, two loads of dung will be ſufficient for three holes, for I could never obſerve any advantage in making theſe beds ſo thick with dung as ſome people do; their crops are ſeldom better, if ſo good, as thoſe which are of a moderate ſubſtance; nor are they forwarder, and the fruit is rarely ſo fair, nor do the Vines continue ſo long in health.

In making theſe beds, you muſt carefully mix the dung, ſhaking it well with the fork, ſo as not to leave any clods of dung unſeparated, as alſo to beat it down pretty cloſe, to prevent the ſteam from riſing too haſtily; you muſt alſo be careful to lay it very even, and to beat or preſs down the dung equally in every part of the bed, otherwiſe it will ſettle in holes, which will be very hurtful. When you finiſh laying the dung, you muſt make a hole exactly in the middle of each light, about a foot deep, and eight or nine inches over; theſe holes muſt be filled with light freſh earth, which ſhould be ſcreened to take out all large ſtones, clods, &c. laying it up in a hill; and in the middle of each thruſt in a ſtick about eighteen inches long, which ſhould ſtand as a mark to find the exact place where the hole is; then earth the bed all over about three inches thick, levelling it ſmooth, and afterwards ſet the frame upon it, covering it with glaſſes: but if there is any apprehenſion of the dung heating too violently, the earth ſhould not be laid upon the bed until the heat is ſomewhat abated, which will be in a few days, and then the earth may be laid upon the bed by degrees, covering it at firſt two inches thick; and a week or ten days after another inch in thickneſs may be laid on, but there ſhould be the whole thickneſs of earth laid upon the bed before the Vines begin to run; and if this thickneſs of earth is at laſt ſix or ſeven inches, the Vines will grow the ſtronger for its being ſo thick; for if the roots are obſerved, they will be found to ſpread and cover the whole bed as much as the Vines extend above; and when the earth is very ſhallow, or too light, the Vines will hang their leaves every day for want of a ſufficient depth of earth to ſupport their roots; ſo that if they are not conſtantly and well watered, they will not have ſtrength to laſt long, nor to produce fair fruit; and the giving them too much water is not ſo proper, nor will it anſwer near ſo well, as the giving a depth of earth upon the dung.

In four or five days time your bed will be in fit order to receive your plants, of which you may eaſily judge by pulling out one of the ſticks which was put in the middle of the holes, and feeling the lower part of it, which will ſatisfy you what condition your bed is in; then you muſt ſtir up the earth in the middle of the hole with your hand, breaking all clods, and removing all large ſtones, making the earth hollow in form of a baſon; into each of theſe holes you muſt plant two plants, in doing which, obſerve to make the holes for the plants a little ſlanting towards the middle of the baſon, eſpecially if your plants are long ſhanked; this is intended to place the roots of the plants as far as poſſible from the dung, to which if they approach too near, the lower part of their roots is ſubject to be burned off; then ſettle the earth gently to each plant, and, if the earth is dry, it will be proper to give them a little water (which ſhould be warmed to the temper of the bed, as was before directed;) and if the ſun ſhould appear in the middle of the day, they ſhould be ſhaded therefrom with mats until the plants have taken root, which will be in two or three days; after which, you muſt let them enjoy as much of the ſun as poſſible, obſerving to turn the lights in the day time to dry, as alſo to give a little air whenever the weather will permit.

You muſt alſo obſerve to keep the glaſſes covered every night, and in bad weather, but be very careful not to keep them covered too cloſe, eſpecially while the bed has a great ſteam in it, which will cauſe a damp to ſettle upon the plants, which, for want of air to keep the fluid in motion, will ſtagnate and rot them.

When your plants are grown to be four or five inches high, you muſt, with ſome ſlender forked ſticks, incline them toward the earth, each one a ſeparate way; but this muſt be done gently at firſt, leſt by forcing them too much, you ſhould ſtrain or break the tender veſſels of the plants, which would be very hurtful to them. In this manner you ſhould, from time to time, obſerve to peg down the runners as they are produced, laying each in exact order, ſo as not to interfere or croſs each other; nor ſhould you ever after remove them from their places, or handle them too roughly, whereby the leaves may be broken or diſplaced, which is alſo equally injurious to them; but whenever you have occaſion to weed the bed between the plants, do it with great care, holding the leaves aſide with one hand, while with the other you pull out the weeds.

In about a month after they are ridged out, you may expect to ſee the beginnings of fruit, which very often are preceded by male flowers, which many people are ſo ignorant as to pull off, calling them falſe bloſſoms; but this I am fully convinced, by many experiments, is wrong; for theſe flowers are of abſolute ſervice to promote the welfare of the fruit, which when theſe male flowers are entirely taken off, does very often fall away, and come to nothing: nor ſhould the Vines be pruned, as is too often the practice of unſkilful people, eſpecially when they are too luxuriant, which often happens when the ſeeds were freſh, or of the laſt year's ſaving, and the plants in good heart. If this ſhould happen to be the caſe, it would be very proper to pull up one of the plants, before they have run ſo far as to entangle with the other; for it often happens, that one or two plants are better than four or five, when they are vigorous; for when the frame is too much crouded with Vine, the fruit is ſeldom good, nor in ſuch plenty, as when there is a more moderate quantity of ſhoots; for the air being hereby excluded from the fruit, they often decay, and fall off very young.

You muſt alſo be very careful to cover the glaſſes every night when your fruit begins to appear, as alſo

to lay a little freſh litter, or mowing of graſs round the ſides of the bed, to add a freſh heat thereto; for if the heat of the bed be ſpent, and the nights prove cold, the fruit will fall away and come to nothing; and when the ſun is extreme hot in the middle of the day, you muſt cover the glaſſes with mats to ſhade the Vines; for although they delight in heat, yet the direct rays of the ſun, when it has great force, are very injurious, by either ſcorching thoſe leaves which are near the glaſſes, or by cauſing too great a perſpiration, whereby the extreme part of the ſhoots and the large leaves are left deſtitute of nouriſhment, and the fruit will be at a ſtand, and often turn yellow before it arrives at half its growth; this is too often the caſe, when the beds have not a ſufficient depth of earth over the dung.

At this time, when your Vines are ſpread ſo as to cover the hot-bed, it will be of great ſervice when you water them, to ſprinkle them all over gently ſo as not to hurt the leaves; but obſerve to do this not at a time when the ſun is very hot, for hereby I have known a whole bed of Cucumbers ſpoiled; for the water remaining upon the ſurface of the leaves in drops, collects the rays of the ſun to a focus, and ſo ſcorches the leaves, that in one day's time they have, from a bright green, become of the colour of brown paper. The watering of the beds all over will be of great ſervice, by giving nouriſhment to thoſe roots, which by this time will have extended themſelves all over the bed; and if the warmth of the bed ſhould now decline, it will be of great ſervice to add a lining of freſh dung round the ſides of the beds, to give a new heat to them; for as the nights are often cold at this ſeaſon, where the beds have not a kindly warmth left in them, the fruit will frequently drop off the Vines, when grown to the ſize of a little finger, and if upon this lining of dung there is a thickneſs of ſtrong earth laid for the roots of the plants to run into, it will greatly ſtrengthen them, and continue the plants in vigour a much longer time; for the roots of theſe plants extend to a great diſtance when they have room, which they cannot have in a bed not more than five feet wide; ſo that when they have no greater extent for their roots, the plants will not continue in vigour above five or ſix weeks, which, if they have depth and extent of earth, will continue three months in bearing; ſo that where there are ſeveral beds made near each other, it will be the beſt way to fill up the bottom of the alleys between them with warm dung, and cover that with a proper thickneſs of earth, ſo as to raiſe them to the level of the beds. Theſe directions, with diligent obſervation, will be ſufficient for the management of this crop of Cucumbers; and Vines thus treated will continue to ſupply you with fruit till the beginning of July, by which time the ſecond crop will come to bear, the ſowing and managing of which is what I ſhall next proceed to.

Culture of Cucumbers under hand or bell-glaſſes.—About the middle of march, or a little later, according to the earlineſs of the ſeaſon, you muſt put in your ſeeds, either under a bell-glaſs, or in the upper ſide of your early hot-bed; and when the plants are come up, they ſhould be pricked upon another moderate hot-bed, which ſhould be covered with bell or hand-glaſſes, placed as cloſe as poſſible to each other; the plants ſhould alſo be pricked at about two inches diſtance from each other, obſerving to water and ſhade them until they have taken new root, which will be in a very ſhort time. This is to be underſtood of ſuch places where a great quantity of plants are required, which is conſtantly the caſe in the kitchen-gardens near London; but where it is only for the ſupply of a family, there may be plants enough raiſed on the upper ſide of the beds where the firſt crop is growing; or if the Vines ſhould have extended themſelves ſo far as to cover the whole bed, whereby there will not be room to prick the plants, a ſingle light will contain ſuch a number of plants, while young, to plant out in ridges, as will ſupply the largeſt family with Cucumbers during the latter ſeaſon. You muſt alſo cover the glaſſes with mats every night, or in very bad weather; but in the day time, when the weather is hot, you muſt raiſe the glaſſes on the oppoſite ſide from the wind, to give air to the plants, which will greatly ſtrengthen them; you muſt alſo water them as you find they require it, but this muſt be done ſparingly while the plants are young.

The middle of april the plants will be ſtrong enough to ridge out, you muſt therefore be provided with a heap of new dung, in proportion to the quantity of holes you intend to plant, allowing one load to ſix holes. When your dung is fit for uſe, you muſt dig a trench about two feet four inches wide, and in length juſt as you pleaſe, or the place will allow; and if the ſoil be dry, it ſhould be ten inches deep, but if wet, very little in the ground, levelling the earth in the bottom; then put in your dung, obſerving to ſtir and mix every part of it as was directed for the firſt hot-beds, laying it cloſe and even.

When this is done, you muſt make holes about eight inches over, and ſix inches deep, juſt in the middle of the ridge, and three feet and a half diſtance from each other; and if there be more than one ridge, the diſtance of thoſe ought to be eight feet and a half from each other; then fill the holes with good light earth, putting a ſtick into the middle of each for a mark, and afterwards cover the ridge over with earth about four inches thick, laying the earth the ſame thickneſs round the ſides. When the earth is levelled ſmooth, you muſt ſet the glaſſes on upon the holes, leaving them cloſe down about twenty-four hours, in which time the earth in the holes will be warmed ſufficiently to receive the plants; then with your hand ſtir up the earth in the holes making it hollow in form of a baſon; into each of which you ſhould plant three or four plants, obſerving to water and ſhade them until they have taken root; after which time you muſt be careful to give them a little air by raiſing the glaſſes on the oppoſite ſide to the wind, in proportion to the heat of the weather, as alſo to water them as you ſhall ſee they require it; but you muſt only raiſe the glaſſes in the middle of the day, until the plants fill the glaſſes, at which time you ſhould raiſe the glaſſes with a forked ſtick on the ſouth ſide, in height proportionable to the growth of the plants, that they may not be ſcorched by the ſun; this alſo will harden and prepare the plants to endure the open air, but you ſhould not expoſe them too ſoon thereto; for it often happens, that there are morning froſts in may, which are many times deſtructive to theſe plants when expoſed thereto; it is therefore the ſureſt method to preſerve them under the glaſſes, as long as they can be kept in without prejudice to the plants; and if the glaſſes are raiſed with two bricks on the backſide, and the forked ſtick on the other ſide, they may be kept in a great while without danger.

Towards the latter end of may, when the weather appears ſettled and warm, you ſhould turn your plants down gently out of the glaſſes; but do not perform this in a very dry, hot, ſunny day, but rather when there is a cloudy ſky, and an appearance of rain; you muſt in doing this raiſe the glaſſes either upon bricks or forked ſticks, whereby they may ſtand ſecure at about four or five inches high from the ground, that the plants may lie under them without bruiſing; nor ſhould you take the glaſſes quite away till the latter end of june, or the beginning of july, for theſe will preſerve the moiſture much longer to their roots than if they were quite expoſed to the open air; about three weeks after you have turned the plants out of the glaſſes, they will have made a conſiderable progreſs, eſpecially if the weather has been favourable, at which time you ſhould dig up the ſpaces of ground between the ridges, laying it very even; then lay out the runners of the Vines in exact order, and be careful in this work not to diſturb the Vines too much, nor to bruiſe or break the leaves; this digging

ging of the ground will looſen it, and thereby render it eaſy for the roots of the plants to ſtrike into it, as alſo render the ſurface of the earth more agreeable to the Vines that run upon it. After this there will be no farther care needful, but only to keep them clear from weeds, and to water them as often as they ſhall require, which they will ſoon ſhew, by the hanging of their greater leaves. The ridges, thus managed, will continue to produce large quantities of fruit from june until the latter end of auguſt, after which time the coldneſs of the ſeaſon renders them unwholeſome, eſpecially if the autumn prove wet.

From theſe ridges people commonly preſerve their Cucumbers for ſeed, by making choice of two or three of the faireſt fruit upon each hole, never leaving above one upon a plant, and that ſituated near the root of it; for if you leave more, they will weaken the plant ſo much, that your other fruit will be ſmall, and fewer in number: but thoſe perſons who value themſelves upon producing Cucumbers very early, commonly leave three or four Cucumbers of the firſt produce of their earlieſt crop, when the fruit is fair; and the ſeeds of theſe early fruit, are generally preferred to any other for the firſt crop. Theſe ſhould remain upon the Vines until the middle or end of auguſt, that the ſeeds may be perfectly ripe; and when you gather them from the Vines, it will be proper to ſet the fruit in a row upright againſt a hedge or wall, where they may remain until the outer cover begins to decay; at which time you ſhould cut them open, and ſcrape out the ſeeds, together with the pulp, into a tub, which ſhould be afterwards covered with a board, to prevent filth from getting amongſt the pulp. In this tub it ſhould be ſuffered to remain eight or ten days, obſerving to ſtir it well with a long ſtick to the bottom every day, in order to rot the pulp, that it may be eaſily ſeparated from the ſeeds; then pour ſome water into the tub, ſtirring it well about, which will raiſe the ſcum to the top, but the ſeeds will ſettle to the bottom; ſo that by two or three times pouring in water, and afterwards ſtraining it off from the ſeeds, they will be perfectly cleared from the pulp; then you ſhould ſpread the ſeeds upon a mat, which ſhould be expoſed to the open air three or four days until they are perfectly dry, when they may be put up in bags, and hung up in a dry place where vermin cannot come to them, where they will keep good for ſeveral years, but are generally preferred when three or four years old, as being apt to produce leſs vigorous, but more fruitful plants.

Culture of Cucumbers in the open ground.—The ſeaſon for ſowing theſe is towards the latter end of may, when the weather is ſettled. The ground where theſe are commonly ſown, is between Cauliflowers, in the wide rows, between which are allowed four feet and a half ſpace when the Cauliflowers were planted. In theſe rows you ſhould dig up ſquare holes at about three feet and a half diſtance from each other, breaking the earth well with a ſpade, and afterwards ſmoothing and hollowing it in the form of a baſon with your hand; then put eight or nine ſeeds into the middle of each hole, covering them over with earth about half an inch thick; and if it ſhould be very dry weather, it will be proper to water the holes gently in a day or two after the ſeeds are ſown, in order to facilitate their vegetation.

In five or ſix days, if the weather be good, your plants will begin to thruſt their heads above ground; at which time you ſhould be very careful to keep off the ſparrows, which are very fond of the young tender ſeed-leaves of theſe plants; and if they are not prevented, will deſtroy your whole crop: but as it is not above a week that the plants are in danger, it will be no great trouble to look after them during that time; for when the plants are come up, and have expanded their ſeed-leaves, the ſparrows will not meddle with them.

You muſt alſo be careful to water them gently, as you find the drought of the ſeaſon may require; and when you perceive the third or rough leaf of the plants begin to appear, you muſt pull out all the weakeſt plants, leaving only three or four of the moſt promiſing and beſt ſituated in each hole, ſtirring the earth round about them with a ſmall hoe to deſtroy the weeds, and raiſe the earth about the ſhanks of the plants, putting a little earth between them, preſſing it gently down with your hand, that the plants may be thereby ſeparated from each other to a greater diſtance; then give them a little water (if the weather be dry) to ſettle the earth about them, which you muſt afterwards repeat as often as you ſhall find it neceſſary, ſtill being careful to keep the ground clear from weeds.

When your Cauliflowers are quite drawn off the ground from between the Cucumbers, you muſt hoe and clean the ground, drawing the earth up round each hole in form of a baſon, the better to contain the water when it is given them; you muſt alſo lay out the plants in exact order as they are to run and extend, ſo that they may not interfere with each other; then lay a little earth between the plants left, preſſing it down gently with your hand, the better to ſpread them each way, giving them a little water to ſettle the earth about them, repeating it as often as the ſeaſon ſhall require, and obſerving to keep the ground clean from weeds. The plants thus managed, will begin to produce fruit toward the end of july, when you may either gather them young for pickling, or ſuffer them to grow for large fruit.

The quantity of holes neceſſary for a family, is about fifty or ſixty; for if you have fewer, they will not produce enough at one gathering to make it worth the trouble and expence of pickling, without keeping them too long in the houſe, for you cannot expect to gather more than two hundred at each time from fifty holes; but this may be done twice a week during the whole ſeaſon, which commonly laſts five weeks; ſo that from fifty holes you may reaſonably expect to gather about two thouſand in the ſeaſon, which, if they are taken ſmall, will not be too many for a private family. And if ſo many are not wanted, they may be left to grow to a proper ſize for eating.

[*Additional directions for the Culture of Early Cucumbers.*

Moſt gardeners valuing themſelves upon having early Cucumbers, I have compreſſed and arranged the foregoing directions; and have added ſeveral others which there are either touched too curſorily or entirely omitted.

1. In the culture of early Cucumbers, that is ſuch as are in perfection during the months of march and april, where there is not a conveniency of ſtoves for raiſing the ſeedling plants, it is proper to have three hot-beds: the firſt ſmall with a ſingle-light frame, for a ſeed-bed, in which the plants are to remain only a few days: the ſecond, a larger ſingle-light, or a two-light frame, for a nurſery-bed, in which the plants are to continue pricked out into pots, till they have formed one joint, and the two firſt rough leaves are from two to three inches broad, which will be in three weeks or a month: the third, a two-light or three-light frame, or frames, in proportion to the quantity that is wanted, for the fruiting hot-bed, into which the plants are finally to be turned out of the pots, with good balls of earth about their roots. If your firſt frame be large enough, or a great number of plants be not wanting; the ſeeds may be raiſed, and the plants pricked out, and brought forward for the fruiting-bed in this, without the ſecond, by means of occaſional linings of dung: and if you have a ſtove, the firſt bed may be diſpenſed with.

The principal circumſtances to be attended to in this ſtage of the buſineſs are, to make the hot-beds on the ſurface, or rather above the ſurface, if your ground be wet; and not to dig a trench for them, as is often practiſed: in order that the bottom of the bed may not be chilled by ſtanding water, and that the whole of it may receive the full benefit of the

linings

linings of dung. To make the ſeedling bed two feet and a half high; and the ſecond three feet and a half, or if the dung be long four feet high. As ſoon as the bed is made, to ſet on the frame; keeping the glaſs down for a day or two to draw up the heat, and then letting out the ſteam by ſetting up the glaſs behind. In ſix, eight or ten days, when the heat begins to abate, to earth the bed five or ſix inches thick, and whilſt the earth is warm to ſow the ſeed in drills, or in ſmall pots; raiſing the light an inch or two behind in the day, and covering it at night with a mat. The beſt ſorts for early crops are, the early ſhort or long prickly Cucumber; (n. 2, 3.) the ſeed ſhould be ſaved from the earlieſt fruit, and ſhould be three or four years old. When the ſeedling plants are come up, and the ſeed-leaves are about half an inch in breadth, prick them out in ſmall pots, filled within an inch of the top with your compoſt earth, and ſet in the frame a day to warm; ſet four plants in each pot, covering them almoſt to the leaves, and watering them gently from bottles ſet a few hours in the frame to take off the cold. Continue to raiſe the lights every day, and ſometimes in the night during the great heat and ſteaming of the bed; in cold weather letting a mat hang looſely over the aperture. When the heat is moderate, the glaſſes ſhould be raiſed only from nine or ten in the morning to three or four in the afternoon, according to the ſeaſon; ſhutting them cloſe before ſun-ſet; and covering them with one, two or three mats, in proportion to the ſeaſon and the warmth of the bed; obſerving not to let the mats hang over the ſides of the bed, and taking them off about eight in the morning. Some perſons put a layer of hay between the mats in ſevere weather. Water the plants moderately once in three, four, five, or ſix days, according to the dryneſs of the earth in the pots, the heat of the bed, or the ſtate of the weather, between eleven and two o'clock; preferring ſun-ſhine for this purpoſe, and having the water ſoft and warm from 65° to 85° of the thermometer, or feeling neither hot nor cold when taken into the mouth. Earth up the young plants in the pots gradually with mould warmed in the frame, till the pots are full. Keep up the heat in the bed as regular as you can from 70° to 80°, by firſt laying dry ſtraw, fern, &c. round the ſides, in about a week: and in a fortnight or three weeks by giving the back and front a lining of hot dung eighteen inches wide at bottom contracting gradually to the top, where it ſhould be covered with earth two inches deep to keep down the ſteam: and in ten days or a fortnight after, lining the ſides, if the heat ſhould decline: guarding on theſe occaſions againſt burning, by raiſing the pots, ſetting up the glaſſes, &c. Some perſons for this purpoſe pour water on the dung; but if too much be poured in, it chills the bed, and if too little, it increaſes the burning.

One of the moſt important operations in this ſtage of the buſineſs is the pruning or ſtopping the young plants, for which directions have been given before under MELON. This is done to promote lateral ſhoots, which are the fruitful ones, and is particularly uſeful in this caſe, where the deſirable point is to procure fruit as early as poſſible. The end of the runner ſhould be taken off almoſt cloſe to the baſe of the ſecond leaf; and the operation is beſt performed when the end of the ſhoot is not bigger than a large pin's head.

2. The plants being thus prepared, in three weeks or a month, when the two or three firſt leaves are between two and three inches broad, they are fit to be finally tranſplanted into the fruiting beds, which the gardeners call *ridging out*. The beds muſt be got ready for this a week or ten days at leaſt before, and where there are ſeveral frames, near a fortnight, in order to have them of a proper temperature for receiving the mould and plants. The height of the beds ſhould be four feet, or three feet and a half at leaſt. As ſoon as they are finiſhed, the frames ſhould be ſet on, and the lights raiſed to give vent to the ſteam as the heat riſes. A long ſtick or two ſhould alſo be thruſt into the bed to judge of its temperature; and it muſt not be moulded till you can bear your finger on the ſticks for ſome time together. You muſt be careful however not to ſtay too long, for a briſk heat is required to bring the young plants forward at firſt.

Make a hillock of mould in the middle of each light ten or twelve inches high, which will require near a buſhel of earth; cover the reſt of the bed three inches thick with the ſame mould; and if you are fearful of the bed's burning, under each hill ſpread a layer of cow-dung, not too wet, eighteen inches or two feet in width, and an inch and half in thickneſs. Having finiſhed this, cloſe the glaſſes, and the next day the bed will be fit for the reception of the plants.

Early in the morning let the pots containing the plants to be ridged out be watered, that the earth may adhere firmly to their roots. One pot being deſtined for each hill, ſhake the plants out, diſturbing them as little as poſſible; and having made a ſufficient hole in the middle of the hillock, place the plants with the ball of earth about them in it, drawing the mould cloſe round and about an inch over them; if the mould be dry, give them a little water that is not cold, and ſhut the glaſſes cloſe. If the leaves flag much, ſhade the lights three or four days with a thin mat in the middle of the day.

Air muſt now be admitted daily by raiſing the lights behind, from half an inch to two or three inches high, according to the weather and the ſtate of the bed; hanging a mat looſely over the aperture when the weather is ſevere. Wet foggy weather however is more to be feared than froſt with ſun-ſhine. At this early ſeaſon, namely the beginning of february, it is ſometimes dangerous to admit air very freely, and yet the lights cannot be kept cloſe on account of the noxious ſteam: in this caſe the introduction of warm air by means of pipes opening into the frames and communicating with the open air through the bed, might be of conſiderable ſervice, and has been practiſed with great ſucceſs. The heat of the beds may alſo be regulated by thermometers, eſpecially where the perſon who manages them has not had long experience in the conduct of hot-beds. It is of great importance to have them kept nearly in the ſame temperature; and Cucumbers at this early ſeaſon require almoſt the ſame heat with the Pine-ſtove.

Mats muſt be put over the glaſſes at ſun-ſet, or ſooner if the weather be cloudy; and muſt be taken off in the morning, ſoon after ſun-riſe, or ſomewhat later in cold cloudy weather. A ſingle mat will be ſufficient at firſt, but as the heat of the beds declines, eſpecially if the weather be ſevere, two or three mats may be laid on, with hay between them if there ſhould be occaſion; remembering not to let them hang much over the ſides of the frame.

During the firſt fortnight examine carefully the ſtate of the hot-bed every day, leſt the heat ſhould become too violent and burn the young plants; the moſt certain indications of this are, the ſickly hue of the plants themſelves, and a whitiſh mouldy appearance at the bottom of the hillocks. This muſt be taken away before it reaches the roots of the plants, and a quantity of freſh earth put in its place. If the heat continues too violent, more of the burnt mould muſt be removed, plenty of air muſt be given to the plants if poſſible, and holes muſt be made in the ſides of the bed, by large ſtakes thruſt into the dung in different places. Some perſons pour water into the dung, to aſſwage the burning heat of the bed.

As ſoon as this danger is over, earth or mould the whole beds at different times to the depth of eight or ten inches; laying the mould for a day or two againſt the ſides and ends of the frames, to acquire a due degree of warmth.

Water moderately once in a week or ten days, or if the weather be warm, twice in that time; and as the ſeaſon advances, ſtill oftener. The beſt time is between

between ten and two o'clock. Let the chill be taken off the water; give it between the Vines, except in very fine weather, when it may be ſprinkled moderately all over the leaves; but if the ſun ſhould ſhine hot, throw a mat over the glaſſes for an hour or two. Whenever you water, ſhut down the lights for half an hour or an hour after.

Train the plants by pruning or ſtopping. In ten days or a fortnight after the firſt ſtopping, the plants will put forth two or three lateral ſhoots or runners; when theſe are advanced two or three joints in length without ſhowing fruit, ſtop each runner at the third joint, to promote their putting out fruitful ſhoots. As the runners advance train them regularly at equal diſtances, pegging them down occaſionally.

When the plants ſhow fruit, which may be expected in three or four weeks, if it have not appeared ſooner from the firſt or ſecond joint, be particularly attentive to keep up a regular heat in the beds; having previouſly laid dry litter or fern round them, then give them proper linings of dung. As ſoon as the heat is conſiderably abated, line the back of the bed directly a foot and half wide; in a week after line the front; and in ten or twelve days after that, ſhake up the firſt lining, adding a little freſh dung to it, and doing the ſame by the ſecond lining: always laying two or three inches of earth on the top of the dung, which ſhould be ſix inches higher than the bed, to allow for ſettling.

In ſetting the fruit, the male bloſſom ſhould be applied to the female on the day it opens, or the day after. It is the cuſtom with ſome to whelm the former over the latter, and to leave it there; but it is better to apply the anthers to the middle of the ſtigmas when they are in a proper ſtate to diſcharge the pollen, and then to throw the male bloſſom away, unleſs males are ſcarce, which ſometimes happens early in the year, and then one may be uſed to impregnate two or three females. Obſerve not to wet the flowers at this period, for that prevents the impregnation of the fruit.

It now remains only to cut off the weak, long-jointed, barren ſhoots, and to thin out the weakeſt and moſt ſtraggling runners, ſo as to be able to train the main vine and principal bearing ſide-runners in a regular manner: to clear away worn-out runners and decayed leaves, and to thin the cluſters of male bloſſoms where they are too large, and to pick them off as they decay: as the ſeaſon advances to ſhade the glaſſes with a ſingle mat occaſionally on ſcorching days; to give them more air by ſetting up the glaſſes higher in front as well as behind; to water them from one to four times a week, according to the heat of the weather; and when the plants are grown ſo large as to preſs againſt the lights, and ſo crowded as to ſhade the fruit too much, to cut out ſome of the leaves, to raiſe the frame three or four inches, and finally, in the middle of june, if the weather be ſettled, to raiſe the frames ſo high, that the Vines may be trained under them, along the ſides of the bed, covering them with mats at night for the firſt week; and thus leaving them till ſome time in july, when the frames may be taken off, and the plants will want no more protection, except in heavy rains, and at night when the weather is not quite propitious.

In this early frame culture of Cucumbers it is neceſſary to remember not to depend wholly upon the firſt ſowing, but to continue to ſow a little ſeed occaſionally, pricking the plants out ſo as to have them of two or three different growths, to ſupply the place of ſuch plants as do not thrive, or may be cut off by the ſeverity of the ſeaſon, burning, ſteaming, *&c.* And if they are not wanting for theſe purpoſes, they will be ready for the ſecond frame-crop. Two crops cultivated in this manner, will furniſh a ſucceſſion of fruit till thoſe which are under hand and bell-glaſſes come in, and theſe will be ſucceeded by thoſe in the open ground; by which means there will be a conſtant ſupply of

fruit from february or march to the middle or end of ſeptember.

Early Cucumbers are in general much eſteemed in private families, and are a valuable article for the market-gardeners, for in march they often fetch thirty ſhillings a dozen; and in april from ten to fifteen ſhillings a dozen is a common price. After this time the price falls every week till auguſt, when thoſe in the natural ground come in, a dozen of which will ſometimes ſcarcely fetch a penny. The quantity of theſe ſold for eating and pickling is prodigious; in the ſummer of 1794, above ten thouſand buſhels were diſpoſed of in one week from the village of Sandy in Bedfordſhire; the gardeners of which ſupply the towns and villages fifty miles round with that and the other produce of their gardens.

The culture under hand-glaſſes and in the open ground being leſs difficult, and having been before ſufficiently diſcuſſed, is not inſiſted upon here.

Such perſons as are not contented with having Cucumbers from february or march to ſeptember, may have them at Chriſtmas or ſoon after by ſowing in october, and treating them in the manner above directed. Thoſe in the open ground may be continued through october and part of november, by placing frames over ſome of the beſt holes, and protecting them with lights during the night and in wet weather. The ſucceſſion may alſo be continued by ſowing the middle of july, and treating them in the ſame manner; or by ſowing the end of july, and tranſplanting into a ſlender hot-bed towards the end of auguſt. Or by ſowing in a ſlight hot-bed at the end of auguſt, and tranſplanting into another about the middle of ſeptember.

By theſe means may a ſucceſſion of Cucumbers be kept up during the latter autumnal and winter months, from the time that thoſe in the open ground go off, till the return of ſuch as are raiſed by the early frame culture in march. But theſe crops cannot be expected to ſucceed like the others, nor in general will they produce any thing more than a few fruit rather for curioſity than uſe.

Cucumbers may alſo be produced in hot-houſes or pine-ſtoves at any time in the winter or very early in the ſpring, with leſs trouble than in hot-beds, but not with the ſame certainty of a crop. For this purpoſe the ſeeds may be ſown in october, and from that time every fortnight during winter, in ſmall pots of rich earth plunged in the bark-pit, and at two or three days old pricked out into other pots, which muſt be alſo plunged into the bark-bed. Having treated the plants like thoſe for ridging out in the early frame-culture, when they are ready to put out runners, tranſplant them into large pots, or rather into boxes three feet long, a foot wide at top, nine inches at bottom, and ten inches deep. Plunge them half way in the bark-bed; or ſet them on the top of the flues; elevating them ten or twelve inches; or place them by means of brackets twelve or fifteen inches below the top glaſſes, a little behind the back walk of the ſtove; putting laths for the vines to run upon, as they advance in length.

Cuttings of Cucumbers taken off five or ſix inches long from healthy plants in the ſummer crops, at the end of ſeptember or the beginning of october, planted in pots of rich mould, plunged into the bark-bed and ſhaded till they have ſtruck, will produce fruit before Chriſtmas. By this method, or by laying, plants may be kept on from year to year.

After all that can be ſaid, in many points much will depend upon the experience, attention and ſagacity of the gardener himſelf.

Two centuries ſince (1597), in the infant ſtate of gardening in this country, Gerarde gives directions for making a hot-bed, whereon Cucumbers, *&c.* may be raiſed. It was to be made in the middle of april or ſomewhat ſooner of ſtable dung, an ell in breadth and depth; it was to be covered with hoops and poles, for glaſſes were not then known; and at

night mats, old painted cloth, or ſtraw were to be thrown over it: the bed was to be covered with rich earth finely ſifted half a foot thick: in this the ſeeds were to be ſown; and the covering being put on, was to remain ſeven or eight days without being taken off: the plants being then come up were to be watered in the middle of the day with water that had ſtood in the houſe or in the ſun; the covering was to be put on every night and taken off every day: and when the plants had four or ſix leaves, and the danger of cold nights was paſt, they were to be replanted very curiouſly with the earth ſticking to them as near as may be, unto the moſt fruitful place, and where the ſun hath moſt force in the garden; covering them with dock leaves or wiſps of ſtraw, propped up with forked ſticks, to keep them from the cold of the night and the heat of the ſun. *Herball*, *p.* 764.

Parkinſon alſo, in 1629, gives directions for making a hot-bed of dung in the ſame manner for Melons; and mentions the covering them with bell-glaſſes.

The firſt account I find of raiſing Cucumbers in autumn to bring fruit about Chriſtmas, is by Mr. Thomas Fowler, gardener to Sir Nathanael Gould, at Stoke Newington. He preſented the king with a brace of well-grown Cucumbers on New Year's day 1721. The ſeeds were ſown on the 25th of ſeptember. *Bradley's huſbandry and gardening*, *vol.* 2. 61 *&* 246. *&* v. 3. 75.

This ſubject, ſo largely treated, of raiſing Cucumbers on hot-beds of dung, ſeems as little capable of ornament as any *; and yet Cowper in the third book of his Taſk †, at the ſame time that he has deſcribed the proceſs with great accuracy, has ſcattered over it ſome of the ſweeteſt flowers of poeſy.

" Grudge not, ye rich, (ſince luxury muſt have
" His dainties, and the world's more num'rous half
" Lives by contriving delicates for you)
" Grudge not the coſt. Ye little know the cares,
" The vigilance, the labor, and the ſkill,
" That day and night are exercis'd, and hang
" Upon the tickliſh balance of ſuſpenſe,
" That ye may garniſh your profuſe regales
" With ſummer fruits brought forth by wintry ſuns.
" Ten thouſand dangers lie in wait to thwart
" The proceſs. Heat and cold, and wind and ſteam,
" Moiſture and drought, mice, worms, and ſwarming flies,
" Minute as duſt, and numberleſs, oft work
" Dire diſappointment that admits no cure,
" And which no care can obviate. It were long,
" Too long, to tell th' expedients and the ſhifts
" Which he that fights a ſeaſon ſo ſevere
" Deviſes, while he guards his tender fruit,
" And oft, at laſt, in vain. The learn'd and wiſe
" Sarcaſtic would exclaim, and judge the ſong
" Cold as its theme, and, like its theme, the fruit
" Of too much labor, worthleſs when produc'd."

DESCRIPTIONS, &c.

[The plants of this genus are very nearly allied to thoſe of *Cucumis*, and are diſtinguiſhed from it chiefly by the ſwelling rim of the ſeed. Like them they are annual, with trailing herbaceous ſtems, furniſhed with tendrils for climbing. Leaves heart-ſhaped, except in *Citrullus*, which has them jagged-palmate. Peduncles ſhort, with one or two flowers. Calyx ſpreading and whitiſh in the firſt ſpecies, yellow in *Citrullus*; bell-ſhaped and yellow in *Melopepo* and *Pepo*, dilated at the baſe with a reflex border in the firſt, narrowed at the baſe with an upright border in the ſecond. Fruit fleſhy (in *Citrullus* juicy), moſtly eatable; in *Melopepo* ſpheroidal, in *Pepo* oblong or various, in *C. lagenaria* long, ſmooth, ſubcylindric, or elſe contracted in the middle [a].

1. Stems thick, long, climbing, with tendrils, branched,] extending near twenty feet in length, covered with a fine ſoft hairy down. [Leaves cordate, roundiſh, repand, toothletted, petioled, alternate, bigландular underneath, ſoft, aſh-coloured, large.] Flowers large, white, on long peduncles, [ſolitary, lateral. Corolla ſpreading, wrinkled, with acuminate diviſions. Fruit ſhaped like a bottle, with a large roundiſh belly and a neck, very ſmooth [b], when ripe of a pale yellow colour, ſome near ſix feet long, and eighteen inches round; the rind becoming hard, and being dried, contain water. [Seeds quadrangular-oblong, cut off and emarginate at top, three-cornered and beaked at bottom, edge keeled with a double raiſed line, ſmoothiſh, of a pale bay colour [c].

The Arabians call the bottle Gourd *Charrab*. The poor people eat it boiled, with vinegar; or fill the ſhell with rice and meat, and thus making a kind of pudding of it. It grows in all parts of Egypt, and in Arabia, wherever the mountains are covered with rich ſoil [d].

In Jamaica the ſhells are generally uſed for water-cups, and frequently ſerve for bottles among the negroes and poorer ſort of white people in the country. A decoction of the leaves is recommended much in purging clyſters; and the pulp of the fruit is often employed in reſolutive poultices: it is bitter and purgative; and may be uſed inſtead of Coloquintida [e].

β. The large Gourd is cultivated on account of the woody ſhell of the fruit, which will frequently contain between twenty and thirty quarts. Where aloes is manufactured in any quantity, it is commonly preferred in theſe ſhells; but in Jamaica they are uſed only to hold water and ſmall grain [f].]

The ſhells are of different forms, ſome ſhaped like a pear, others like a bottle, others again like an orange.

[Native of both Indies. Cultivated 1597 [g].

2. Stem furrowed, climbing, covered with aſh-coloured hairs. Leaves petioled, having five angles, or ſublobed, with ſtraight angles, nerved, villoſe on both ſides. Petioles round, hiſpid, a finger's length. Flowers axillary, very cloſely ſet with ferruginous hairs; the lower a finger's length, the upper ſhorter. Tendrils ſimple, bifid or trifid. Calyx and peduncle very cloſely hirſute, with ferruginous hairs. Native of Japan, where it flowers in ſeptember [h].

3. The herb and flowers are very like the Pompion, but this is not ſo rough. The leaves are not many-cleft, neither is the fruit bitter. The tendrils are ſtraight, and end in ſmaller ſpiral tendrils, uſually ſeven in number. Fruit ſmooth and even, the ſize and form of an hen's egg, with the rind ſo hard as ſcarcely to be cut with a knife, painted with ten milk-white longitudinal lines, as if it were a hybridous production of *Bryonia laciniosa*.

Native of Perſia, about Aſtracan [i].

4. Stems thick, angular, extremely hiſpid, branched, climbing by means of bifid tendrils,] or ſpreading to the diſtance of forty feet, ſo that a ſingle plant, if properly encouraged, and all the ſide branches permitted to remain, will overſpread twenty rods of ground. [Leaves cordate, large, roundiſh-angular, toothed, wrinkled, hairy on both ſides, on long, alternate, thick, flexuoſe, hirſute petioles. Flowers yellow, lateral, ſolitary, on peduncles reſembling the petioles, but ſhorter. Teeth of the calyx large, gaſhed, waved, reflex [k]. Fruit roundiſh, ovate-globular or oblong-ovate; pale green on the outſide, and commonly hiſpid, with briſtly hairs; within having a ſpongy inſipid white pulp or fleſh; divided in the middle into three primary cells, each of which is double, and theſe are ſubdivided into the proper cells of the ſeeds, which are very numerous, horizontal, elliptic, of a compreſſed lens ſhape, ſmooth, whitiſh, encircled with a rounded tumid margin, and within that with a raiſed line: it has four coats, the outmoſt very thin and tranſparent; the next leathery, brittle and white; the third ſomewhat fleſhy and green, and the inmoſt membranaceous and cobwebbed: albumen none: embryo elliptic, white; ſeed-leaves fleſhy, ſlightly convex on the outſide, flat within, veiny-wrinkled [l].]

The fruit varies in form and ſize; two hundred and ſixty of them, on an average the ſize of half a peck, have been produced from a ſingle plant in New England. In Europe the Pompion, which we have corrupted to Pumpkin, is frequently planted by the country people on their dunghills, and ſuffered to trail at length over the graſs of an orchard. When the fruit is ripe, they cut a hole on one ſide, and having taken out the ſeeds, they fill the void with ſliced apples, adding a little ſugar and ſpice, and bake it; but it is eſteemed hard of digeſtion. [In the Eaſtern countries, it is reckoned the moſt wholeſome of the Cucurbitas, and is even given to the ſick, as being cooling and diuretic. Its natural place of growth is not known.

It flowers from june to auguſt; and was cultivated here before 1570, as appears from Lobel [m].

Formerly Pompions were called in Engliſh Melons, or corruptly Millions; and the true Melons, Muſk-Melons.

5. The plant, flower and ſeeds of this are the ſame as in the Pompion; but the fruit is ſmaller, with a harder rind, that is almoſt woody [n]. Loureiro is of opinion that it is no more than a variety of the next ſpecies.]

The warted Gourd is very common in moſt parts of America, where it is cultivated as a culinary fruit. It varies in form and ſize, being round, flat, ſhaped like a bottle, or oblong; the rind is white when the fruit is ripe, and covered with large protuberances or warts. It is commonly gathered when half grown, and boiled by the inhabitants of America to eat as ſauce with their meat. In England it is cultivated only as a curioſity, a variety of better eſculent plants being in ſeaſon here, when theſe are fit for uſe.

[Cultivated in 1731, by Mr. Miller [o].

6. Stem roundiſh, hairy, procumbent or climbing, with trifid tendrils; branches many, long. Leaves lobed-angular, ſerrate, hairy, alternate, on long petioles. Flowers yellow, on lateral, one-flowered peduncles: ſegments of the calyx linear-ſpatulate, ſpreading: anthers linear, diſtinct, erect. Fruit large, reddiſh-yellow or yellowiſh-white within and without, commonly roundiſh, often flatted at top and bottom, always toruloſe, ſometimes ovate, ſeldom warted.

This, ſays Linneus, has tendrils on the ſtem, though it be neither climbing nor procumbent. In this, however, he is miſtaken, for Loureiro informs us, that in India it is always ſcandent, when a ſupport is at hand, but when there is none, it is procumbent [p].]

Mr. Miller alſo remarks, that it often grows with a ſtrong buſhy erect ſtalk, without putting out runners from the ſide like the other ſorts, but that after it has been cultivated a few years in the ſame

[a] Juſſieu. [b] Loureiro. [c] Gærtner.

[n] Linn. ſpec. [o] Hort. kew. [p] Loureiro.

garden, the plants will become trailing: and that ſeeds out of the ſame fruit have produced erect plants bearing the ſame fruit with the parent, in one garden; and in another, trailing plants, with larger fruit, of a different ſhape. It is common in North America, where it is cultivated for the ſame purpoſes as the preceding. [Alſo in the Eaſt-Indies, China, &c. The fruit is of great uſe in long voyages, for it may be kept ſeveral months freſh and ſweet[5].

Cultivated in 1597[6].

7. Stem round, ſtriated, long, branched, hairy, procumbent, diffuſed, with lateral bifid tendrils. Flowers yellow, on ſhort, ſolitary, lateral peduncles. Fruit large, ſmooth, round or oblong, a foot and half in length, within watery, ſweet, very red or pale. Seeds black or ruſous[7].] The fruit varies much in form and colour. It is cultivated in the warm countries of Europe, alſo in Aſia, Africa and America, where it is greatly eſteemed for its wholeſome cooling quality. In England it is not much regarded.

[Native of the ſouth of Europe, and cultivated before 1597 by Gerarde[8].

It ſerves the Egyptians for meat, drink and phyſic. It is eaten in abundance during the ſeaſon, which is from the beginning of may until the overflowing of the Nile, that is, to the end of july, or beginning of auguſt. It is the only medicine the common people uſe in ardent fevers. For this purpoſe they have a variety that is ſofter and more juicy than the common ſort: when this is very ripe, or almoſt putrid, they collect the juice, and mix it with roſe water and a little ſugar. This fruit ſhould be eaten by Europeans with great caution: when taken in the heat of the day, whilſt the body is warm, colics and other bad conſequences often enſue; and it is well known that perſons are much troubled with worms, at the time this fruit is in ſeaſon[9].

Gerarde calls the Water-Melon *Citruls*, *Cucumber Citruls*, and *Pome Citruls*. Parkinſon, the *Citrull* or *Turkie Million*.

Three other ſpecies of Cucurbita are mentioned to grow in the Society iſles, which Forſter has named—pruriens, aſpera & multiflora. *Flor. auſtr.* n. 554, 555, 556.]

PROPAGATION AND CULTURE.

1 to 6. Theſe may be propagated by ſowing their ſeeds in april, on a hot-bed; and when the plants come up, they ſhould be tranſplanted on another moderate bed, where they ſhould be brought up hardily, and have a great deal of air to ſtrengthen them; and when they have got four or five leaves, they ſhould be tranſplanted into holes made upon an old dunghill, or ſome ſuch place, allowing them a great deal of room to run, for ſome of the ſorts will ſpread to a great diſtance.

The firſt ſort requires to be treated more tenderly than the others, in order to procure ripe fruit; the ſeeds therefore ſhould be ſown upon a moderate hot-bed in april, and the plants afterward planted each into a penny pot, and plunged into a very moderate hot-bed to bring them forward; but they muſt not be tenderly treated, for if they have not a large ſhare of free air admitted to them every day, they will draw up weak. When the plants are grown too large to be continued in the pots, there ſhould be holes dug where they are deſigned to grow, and three or four barrows full of hot dung put into each; theſe ſhould be covered with earth, into which the plants muſt be planted, and covered with hand-glaſſes till they run out.

There are ſome people who ſet theſe plants by the ſides of arbours, over which they train the vines; ſo that in a ſhort time they will cover the whole arbour, and afford a ſtrong ſhade, and upon ſome of theſe arbours I have ſeen the longeſt fruit. There are others who plant them near walls, pales, or hedges, to which they faſten the Vines, and train them to a great height: the Orange-ſhaped Gourd is the ſort which is moſt commonly ſo planted for the ornament of its fruit, which has a pretty effect, eſpecially when ſeen at ſome diſtance. All the ſorts require a large ſupply of water in dry weather.

7. Firſt provide ſome ſeeds, which ſhould be three or four years old; for new ſeeds are apt to produce vigorous plants, which are ſeldom ſo fruitful as thoſe of a moderate ſtrength. The beſt ſorts to cultivate in England, are thoſe with ſmall round fruit, which come from Aſtracan, thoſe with very large fruit ſeldom ripen well in this climate. Prepare a heap of new dung the beginning of february, which ſhould be thrown in a heap for about twelve days to heat, turning it over twice, mixing it well; then make a hot-bed in which theſe ſeeds, as alſo Cucumber-ſeeds and Muſk Melons may be ſown. The dung ſhould be well wrought in making the bed, and muſt be beaten down pretty cloſe with a dung-fork, that the heat may not be too violent, but of longer continuance. When the dung is thus laid, cover it about four inches thick with good light earth, and having ſpread it very even, put the frame and glaſs over it, leaving it to warm four or five days before you put the ſeeds into it, obſerving, if the ſteam riſes pretty much, to raiſe up the glaſs to let it paſs off: then, if you find your bed in proper temper, you may ſow your ſeeds therein in drills, covering them over with earth about half an inch. After this, if you find your bed very warm, you muſt give air in the day-time by raiſing the glaſſes; but if the bed is cool, you muſt cover it well with mats every night, as alſo in bad weather. In four or five days after, you muſt prepare another hot-bed to receive theſe plants, which will be fit to tranſplant in ten days, or a fortnight at moſt, after the ſeeds are ſown; this bed need not be very large, for a few of theſe plants will fill a large quantity of frames, when they are planted out for good, and while the plants are young, there may be a great quantity kept in one light; ſo that thoſe perſons who raiſe early Cucumbers and Muſk Melons, may alſo raiſe theſe plants in the ſame bed; for two or three lights will be ſufficient to raiſe plants of all three kinds, to ſupply the largeſt families, until they are planted out for good. In the management of theſe plants while young, there is little difference from the directions given for raiſing Muſk Melons, therefore I need not repeat it here. The chief thing to be obſerved, is, to let them have a large ſhare of air whenever the weather will permit, otherwiſe the plants will draw up weak, and be good for little. As theſe plants will require two or three hot-beds to bring the fruit to perfection, it will be the better way to put the plants into baſkets, when they have gotten four leaves, as is directed for raiſing early Cucumbers; but you ſhould not plant more than two plants in each baſket, for if one of them lives it will be ſufficient; therefore when both the plants ſucceed, you ſhould draw out the weakeſt and moſt unpromiſing, before they begin to put out their ſide ſhoots, otherwiſe they will entangle and render it difficult to be performed, without greatly injuring the remaining plant.

The baſkets in which theſe plants are to be planted, need not be more than a foot diameter; ſo that one light will contain eight of them, which will be ſufficient for twenty-four-lights, when they are planted out for good; for where the plants are vigorous, one ſingle plant will ſpread ſo far as to fill three lights; and if they have not room, they ſeldom ſet their fruit well.

Theſe baſkets may remain in the nurſery-beds until the plants have ſpread, and put out many runners; for when the heat of this bed declines, it is ſoon revived by adding a proper lining of warm dung to the ſides of the bed quite round; ſo that when they are taken out of this bed, and placed in the ridges where they are to remain, the heat of the beds will laſt ſo long as to ſet their fruit, which is of great conſequence; for when the plants are ridged out

[5] Loureiro. [6] Hort. kew.
[7] Loureiro. [8] Hort. kew. [9] Haſſelquiſt.

out very young, the beds are generally made of great thickneſs in dung, in order to continue their heat; ſo that for ſome time after they are made, they are ſo extreme hot, as to endanger the ſcalding of the plants; and by the time the fruit begins to appear, there is little heat left in the beds, which often occaſions the fruit to drop off, and come to nothing.

After theſe plants are placed in the beds where they are to remain, carefully lead the ſhoots as they are produced, ſo as to fill each part of the frame, but not to croud each other; and be careful to keep them clear from weeds, as alſo to admit freſh air whenever the weather will permit; they muſt alſo be frequently watered, but do not give it them in great quantities. In ſhort, there is little difference to be obſerved in the management of theſe from that of Muſk Melons, but only to give them more room, and to keep the beds to a good temperature of heat, and when the fruit appears, to admit air freely to the plants, in order to ſet their fruit; but when the nights are cold, the glaſſes muſt be covered with mats to keep the beds warm, without which this fruit will ſeldom come to good in this country.

DESCRIPTION, *&c.*

[Root annual, round, ſcarcely branched. Stem a palm in height;] Miller ſays, it ſeldom riſes more than nine or ten inches high in the warm countries where it is cultivated, and that he has never ſeen it grow more than three or four inches high in England. [It is ſmooth, ſtriated, branched from the bottom, flexuoſe, and divaricately panicled. Leaves ſubbiternate, the lateral leaflets being binate or bifid, and the end one trifid; all the ſegments unequal, filiform, and an inch long: the uppermoſt leaves are only ternate, the middle leaflet longer than the two others.] According to Miller, the leaves are divided into long narrow ſegments like thoſe of Fennel, but much ſmaller; they are of a deep green, and generally turn back at the end. [Peduncles oppoſite to the leaves, ſpreading the length of the internodes. Rays of the umbel from four to ſix, nearly equal, ſpreading, the third of an inch in length. Univerſal involucres of two or three ſubulate, unequal leaflets, the length of the umbellets, ſometimes trifid. Three or four flowers, ſeldom five, in each umbellet. Pedicels unequal, about the ſame length with the fruits. Involucels often as many as the flowers, leaflets unequal, briſtle-ſhaped and acuminate, the length of the umbellets. Corollas purpliſh or pale bluſh-colour, rayed. Fruit oblong, thicker in the middle *; the ſame ſize with that of fennel, and aromatic; terminated by the erect toothlets of the calyx, and the two ſhort reflex. ſtyles; ſtriated, ſomewhat hiſpid, pale. Seeds convex on one ſide, on which are nine ſtreaks, and minute briſtles ſcattered over it; the other ſide is flat *.

Native of Egypt. It flowers in June and July. Cultivated in 1594, by Sir Hugh Plat *. Gerarde ſays, he has proved the ſeeds in his garden, where they have brought forth ripe ſeed much fairer and greater than any that cometh from beyond the ſeas. He ſowed it in the midſt of may, it ſprung up in ſix days, and the ſeed was ripe in the end of july. It is ſingular, therefore, that the Cumin ſhould never produce ſeeds with Mr. Miller.

It is cultivated in the ſouth of Europe, and all Leſſer Aſia.] In the iſland of Malta, where it is much propagated for ſale, it is called *Cumino aigro*, hot Cumin, to diſtinguiſh it from Aniſe, which they call *Cumino dolce*, or ſweet Cumin.

PROPAGATION AND CULTURE.

If the ſeeds of this plant are ſown in ſmall pots filled with light kitchen-garden earth, and plunged into a very moderate hot-bed to bring up the plants, and theſe after having been gradually inured to the open air, turned out of the pots, and planted in a warm border of good earth, preſerving the balls of earth to their roots, and afterwards kept clean from weeds; the plants will flower pretty well, and by thus bringing them forward in the ſpring, they may perfect their ſeeds in very warm ſeaſons.

Thymus pulegioides. *Lin. ſpec. edit.* 1. 592.
Leaves oval, very entire; flowers in whorls, ſtem four-cornered.

4. Cunila capitata.
Lin. ſyſt. 67. *ſuppl.* 87.
Leaves ovate; flowers terminating; umbel roundiſh.

DESCRIPTIONS, *&c.*

1. Perennial. Native of North America. It flowers from july to ſeptember, and was cultivated in 1760, by Mr. James Gordon [a].]

There are two varieties of this; one has narrower leaves and larger heads, and the leaves have very little ſcent; whereas thoſe of the common ſort ſmell ſo like Pennyroyal as not to be diſtinguiſhed from it.

[2. Annual. A ſpan high, and brachiate. Leaves lanceolate-ovate, roughiſh, with one or two teeth; the upper ones narrower. Whorls of flowers the whole length of the plant. Bractes two on each ſide, larger than the flowers, beſides other minute ones. Calyx rough; the upper lip three-cleft and acuminate; the lower ſetaceous. Corolla white, with a violet-coloured throat; the upper lip ſcarcely emarginate [b]. It has a ſtrong ſcent, and an infuſion of it is uſed in North America, by perſons who have taken cold, or have pains in their limbs [c].

Native of North America, in dry places; flowering with us in auguſt. Introduced 1777, by Monſ. Thouin [d].

3. Annual. It has the air of the foregoing. Stem erect, a ſpan in height; with a few, ſimple, ſhort branches. Leaves obtuſe, ſmooth, ſtriated underneath. Whorls of flowers the whole length of the ſtem. Native of the country about Montpellier [e].

4. Stem a palm in height. Leaves ſomewhat oblong, naked. Calyxes ſmooth and even, ſtreaked. Corollas purple. Anthers black. Native of Siberia [f].

PROPAGATION AND CULTURE.

Theſe plants are all hardy, and may be propagated from ſeeds, which they ſometimes produce here. The firſt ſort may alſo be increaſed by planting cuttings in the ſpring, in the ſame manner as is practiſed for Mint; they will take root freely, and if they are planted in a moiſt ſoil will thrive exceedingly.

ESSENTIAL CHARACTER.

Cal. very ſmall, four-toothed. *Cor.* four-cleft, with a ſhort tube. *Berry* crowned, with a two-celled, two-ſeeded nut.

SPECIES.

1. Cunninghamia ſarmentoſa.

DESCRIPTION, *&c.*

This, which is the only ſpecies known, is a ſort of ramping ſhrub, with a ſtem about ſix feet high, and four or five inches in diameter. The bark is reddiſh, wrinkled, and cloven: the wood is whitiſh: as the ſhrub grows, it puſhes out towards right and left long twiggy branches, which apply themſelves to the trunks of large trees, and inſenſibly climb to their tops, where they ſpread themſelves by puſhing forth a conſiderable number of long twiggy branches, many of which hang pendant to within ſix or eight feet of the ground. Theſe branches are knotty, covered with a reddiſh down, and bear at each knot a pair of oppoſite leaves, diſpoſed croſſwiſe: they are entire, wrinkled, oval, green above, beneath reddiſh and downy. The border of theſe leaves is often a little rolled inwards: the nerves are prominent: the footſtalk ſhort. At the baſe of the leaves on each ſide is a large weak ſtipule, which is downy, and ſoon falls off: the largeſt leaves are about four inches and a half long, and about three broad. The flowers, which are ſmall, grow in ſpikes, proceeding from the boſoms of the leaves towards the extremities of the twigs: their colour is blueiſh; the calyx reddiſh. This ſhrub is found on trees which grow near the crique de Galibis.

Cal. five-leaved. *Pet.* five, cowled at the top. *Style* trifid. *Capf.* three-celled. *Seeds* solitary, arilled.

SPECIES.

1. Cupania tomentosa.
   Swartz prodr. 61.
   Trigonis tomentosa. *Jacqu. amer.* 102. *t.*
   Leaves pinnate obovate retuse, ferruginous-tomentose underneath.
2. Cupania glabra.
   Swartz prodr. 61. *Brown. jam.* 178. *Plum. gen.* 45. *ic.* 110.
   C. americana. *Lin. spec.* 290. *syst.* 864. *Reich.* 4. 190. *Gaertn. fruct.* 2. 469.
   Leaves pinnate ovate obtuse crenate smooth.
3. Cupania saponarioides.
   Swartz prodr. 62.
   Leaves pinnate oblong entire, rugged underneath.

DESCRIPTIONS, *&c.*

1. Jacquin describes his Trigonis as a small upright tree, twelve feet in height. The younger branches and ribs of the leaves are slightly tomentose. Leaves alternate, half a foot long: lealets usually three pairs, without an odd one, oblong, attenuated at the base, emarginate, serrate, smooth on the upper, tomentose on the lower surface, alternate, the outer ones largest, and frequently half a foot in length longer than the rib. Racemes simple, erect, axillary, seven inches long; the pedicels short. Flowers small, numerous, with yellowish petals, in the shape of an isosceles triangle inverted; whence the name Trigonis. Native of Hispaniola in woods.

2. This shrubby tree is common in the lower hills of Jamaica, where it is called Loblolly-tree. It rises to the height of twelve or fourteen feet. The leaves are large, and the wood soft and useless [b].

Capsule of a dusky ferruginous colour, opening into three parts at the tip, scarcely to half its length, and quite entire at bottom: the sutures of the valves towards the top have a narrow groove, but the sides have a deep one, to which the partitions correspond within. Seeds solitary, brown: aril incomplete, spongy-membranaceous, of a dirty white colour, funnel-shaped; with a solid beak, but the cup involving the seed half way, and ending in a repand toothless margin [c]. The preceding species has a silky white fruit, and two seeds in each cell, according to Gærtner; who doubts, however, whether these be really distinct.

3. Native of the West-Indies [d].

Leaves in four rows, ſickled compreſſed furrowed decurrent.

7. Cupreſſus columnaris.
Forſt. flor. auſtr. n. 351.
Leaves imbricate ſubulate furrowed; ſtrobiles cylindric elongated.

DESCRIPTIONS, *&c.*

1. Stem upright, with many round branches, either growing upright (α), or ſpreading abroad (β); ſtrigoſe and toothed with the rudiments of leaves. Fronds dichotomous, ſubquadrangular; leaflets alternately oppoſite, decurrent, ſubcarinate, the older ones diſtant and mucronate, the younger cloſely imbricate. Fruit globular or ſomewhat ovate, on the ſides, or at the ends of the branches, when unripe dark green. It is a cone or ſtrobile, called by Varro *galbulus*, and is compoſed of large, angular, peltate, corky ſcales, ſlightly convex on the outſide, ſtreaked in rays, and mucronate in the centre, becoming woody, and ſeparating when ripe, on the inſide ending in a thick angular peduncle, to the extremity of which four little nuts adhere, which are bony, obovate, compreſſed, or irregularly angular, covered with a thin membranaceous ſkin of a dun colour, and produced into a very narrow rim ſurrounding the nut: it is one-celled, valveleſs, and is eaſily cut with a knife. Seed linear-oblong, ſubcolumnar, bay-coloured *.

Native of the Levant, Candia, Rhodes, Malta, &c.; Carinthia; Apulia, where Dr. Symonds informs us it is very frequent, and that he ſaw trees thirty feet high on monte Gargano; in ſome parts of the Ruſſian empire; in China, and probably in many provinces of Aſia.

We learn from Turner that it was cultivated here in Sion garden, in 1551 †. Gerarde alſo mentions its growing at Sion, Greenwich, and at Hampſtead in the garden of Maſter Waide, one of the Clerks of her Majeſty's Privy Council.

It is ſaid that there are ſtill growing in the garden of the Palace of Generaliſe at Grenada, ſeveral ſuperb and lofty Cypreſſes, which were large trees in the reign of Andeli, the laſt Mooriſh King, three centuries ago. Theſe trees are ſtill called *Los Cypreſſes de la Reyna Sultana*, from the Princeſs having been falſely accuſed of committing adultery under them with *Abencerrage* ‡. The Cypreſs will live to a great age, if what Pliny ſays § be true, that there were in his time at Rome trees more ancient than the city itſelf. Modern Rome boaſts ſome very fine Cypreſſes by the palaces and in the gardens of ſome of the villas, though not of ſuch high antiquity; and no tree blends ſo well as this with ſtone buildings.

Mr. Miller diſtinguiſhes ſpecifically the upright from the ſpreading Cypreſs. According to his account, [the firſt of theſe trees is very common in moſt of the old gardens in England, but at preſent is not ſo much in requeſt as formerly, though it is not without its advantages; nor ſhould it be entirely rejected, although many perſons are of that opinion; for it ſerves to add to the beauty of wilderneſſes, or clumps of Evergreens; and where they are properly diſpoſed, they have their beauties. It was formerly planted in borders of pleaſure-gardens, and kept ſhorn into a pyramidal or conic form: and ſome people, believing them ſubject to be killed if they cut them, tied them up with cords into a pyramidal figure, which form they are naturally diſpoſed to grow in; but this winding them about, prevented the air from entering the inward parts of the branches, ſo that the leaves decayed, and became unſightly, and greatly retarded their growth. And thoſe which are ſheared, if the operation is not performed in the ſpring, or early in the ſummer, are very ſubject to be injured by ſharp winds and cutting froſts in winter. Wherefore, upon the whole, I think it much better to ſuffer them to grow wild as they are naturally diſpoſed, planting them only amongſt other Evergreen Trees, where, by the darkneſs of their green leaves, together with their waving heads, they will greatly add to the variety.

The ſecond is by far the largeſt growing tree, and is the moſt common timber in ſome parts of the Levant. This, if planted upon a warm, ſandy, gravelly ſoil, will proſper wonderfully; and though the plants of this ſort are not ſo finely ſhaped as thoſe of the firſt, yet they greatly recompenſe for that defect by their vigorous growth and ſtrength, in reſiſting all weathers. This tree is very proper to intermix with Evergreens of a ſecond ſize next to Pines and Firs, to form clumps; in which claſs it will keep pace with the trees of the ſame line, and be very handſome. Beſides, the wood of this tree is very valuable, when grown to a ſize fit for planks, which I am convinced it will do in as ſhort a ſpace as Oaks; therefore, why ſhould not this be cultivated for that purpoſe, ſince there are many places in England where the ſoil is of a ſandy or gravelly nature, and ſeldom produces any thing worth cultivating? Now, in ſuch places theſe trees will thrive wonderfully, and greatly add to the pleaſure of the owner, while growing, and afterwards render as much profit to his ſucceſſors, as perhaps the beſt plantation of Oaks; eſpecially ſhould the timber prove as good here as in the iſlands of the Archipelago, which I ſee no reaſon to doubt of; we find it was ſo gainful a commodity to the iſland of Candia, that the plantations were called *des filiæ*, the felling of one of them being reckoned a daughter's portion.

[The march and april winds, ſays Mr. Evelyn, in 1683 and 1665, accompanied with cruel froſts and cold blaſts for more than two months, did not, amongſt near a thouſand Cypreſſes growing in my garden, kill above three or four, which had been cut the latter end of october. As for the froſt of thoſe winters, than which, I believe, there was never known a more cruel and deadly piercing one ſince England had a name, it did not touch a Cypreſs of mine, till it joined forces with that deſtructive wind.

Notwithſtanding the above recommendation of Miller, and the account of its hardineſs by Evelyn, the Cypreſs has never been planted in any quantity among us, evidently becauſe it cannot reſiſt the attacks of our winter froſts and ſpring blaſts.]

The timber of this tree is ſaid to reſiſt the worm, moth, and all putrefaction, and is ſaid to laſt many hundred years. The doors of St. Peter's church at Rome were framed of this material, which laſted from Conſtantine to Pope Eugenius IVth's time, which was eleven hundred years, and were then found and entire, when the Pope changed them for gates of braſs. The coffins were made of this material, in which Thucydides tells us the Athenians uſed to bury their heroes; and the mummy cheſts, brought with thoſe condited bodies out of Egypt, are many of them of this wood.

This tree is recommended for the improvement of the air, and a ſpecific for the lungs, as ſending forth great quantities of aromatic and balſamic ſcents; wherefore many of the antient phyſicians of the Eaſtern countries uſed to ſend their patients, who were troubled with weak lungs, to the iſland of Candia, which at that time abounded with theſe trees. [However that may be, the Cypreſs is valuable on account of its wood, which is of a duſky or brownish red colour, has a ſweet ſmell, and on account of its hardneſs is fit for a variety of purpoſes. It is ſit, ſays Evelyn, for cheſts and other domeſtic furniture; harps and other muſical inſtruments, being a ſonorous wood; for ſtakes to vines, pales, rails and planks; of which there were at Venice above four feet in breadth. In Crete and Malta it is uſed in building.

* Pallas, Gærtner. † Hort. kew.
‡ Townſ. travels. § B. 16. ch. 44.

The Cypreſs among the ancients was ſacred to Pluto and Proſerpine, and was uſed at funerals, eſpecially of perſons of faſhion:

" Et non plebeios luctus teſtata cupreſſus." *Lucan.*

It was placed in front of the houſe, or in the veſtibule, that no perſon who was to perform any ſacred rites might enter a place polluted with a dead body: and the reaſon aſſigned for its uſe on this melancholy occaſion was, that the Cypreſs when once cut down never ſprings up again. It would be an improper emblem, therefore, in a Chriſtian country. The uſe of evergreens at funerals is yet not uncommon among us; but they are ſuppoſed to be ſignificant of immortality, at the ſame time that their balſamic ſcent guards the attendants againſt the ill ſmells and infection that may be apprehended from a putrid body.

On account of its durability Plato would have the laws and ſacred rites inſcribed on Cypreſs tablets: and Pliny relates (16. 40.) that the ſtatue of Jupiter in the Capitol, made of this wood in the year of Rome 661, was found in his time.]

2. The ſecond ſort is a native of America, where it grows in watery places, and riſes to a prodigious height, and is of a wonderful bulk. I have been informed that there are trees of this kind in America which are upwards of ſeventy feet high, and ſeveral fathoms in circumference, which trees grow conſtantly in the water; therefore they may probably be of ſingular advantage to plant in ſuch ſwampy or wet ſoils where few other trees will grow, eſpecially of the reſinous kind. That they are very hardy in reſpect to cold, is evident from ſome few trees of this kind which were formerly planted in England; particularly one in the gardens of John Tradeſcant, at South Lambeth, near Vauxhall, which is upwards of thirty feet high, and of a conſiderable bulk; though in a common yard, where no care is taken of it, but, on the contrary, many hooks are driven into the trunk to faſten cords thereto for drying cloaths, yet the tree is in great health and vigour, but has not produced any fruit, which may be occaſioned for want of moiſture: for we often ſee many aquatic plants growing upon a drier ſoil, but are ſeldom ſo productive of either flowers or fruit as thoſe which grow in the water.

[John Tradeſcant, ſenr. introduced this tree from Virginia, before the year 1640[a]. His tree at South Lambeth has long been deſtroyed, together with all the other trees and plants in his curious garden there.]

Another large tree of this ſort in the gardens of the late Sir Abraham Janſſen, Bart. at Wimbledon in Surry, produced great quantities of cones for ſome years, which in favourable ſeaſons came to maturity, and the ſeeds were as good as thoſe which have been brought from America. This tree was tranſplanted when it was very large, which ſtinted its growth; and this may have occaſioned its fruitfulneſs, for it made very little progreſs in its growth after it was removed. [This tree in ſummer reſembles an evergreen; the leaves have a pleaſing effect, appearing like ſome ſorts of Acacia[b].

3. This grows to a conſiderable ſize in North America, of which it is a native. With us it ſeldom riſes much higher than fifteen feet; when raiſed from cuttings it has rather the appearance of a ſhrub, and is not above nine or ten feet high. Loureiro informs us, that in China and Cochinchina, where it alſo grows naturally, it is only about eight feet in height. The branches are numerous, and ſtand two ways; the tree naturally forms itſelf into a regular head: the leaves are evergreen, flat, ſharp, very ſhort, imbricated, and reſemble thoſe of the *Arbor Vitæ*; they are ſmall, and of a browner green than the Common Cypreſs.] The fruit is blue, and no larger than the berry of the Juniper, from which it is not eaſily diſtinguiſhed at a little diſtance; but it is a perfect cone or ſtrobile, having ſeveral nuts like that of the common Cypreſs.

[It is abundant in the ſwamps of New Jerſey, and ſome parts of Pennſylvania and New York; but not to the north of Goſhen, lat. 41° 25′. The number, however, has been greatly reduced, and as this tree requires to be of eighty years growth from the ſeed before it can be uſed for timber, poſterity will probably find the want of this uſeful tree in America. It is uſed for fencing, and even for poſts, but it does not laſt in the ground ſo well as the red Cedar (Juniperus virginiana); it makes good canoes; hoops and other cooper's ware. Many houſes are built of it; but it is in the higheſt eſteem for ſhingles; and for that purpoſe great quantities are ſent to the town of New York. It is alſo exported to the Weſt-Indies both for ſhingles and pipe ſtaves[c].]

This tree, planted in a ſtrong moiſt ſoil, may become profitable for timber, and growing in a climate much colder than England, there is no hazard of its ſucceeding in the open air here. However this may be, being an evergreen of regular growth, and thriving in cold ſituations and a moiſt ſoil not adapted to trees of this family, it is a great ornament to large plantations. [It was introduced among us in 1736, by Peter Collinſon, Eſq.[d].]

4. The young plants raiſed here from ſeeds have looſe ſpreading branches, cloſely beſet with narrow ſtraight leaves, alternately oppoſite, near an inch long, of a light green colour, and continuing in verdure all the year. The cones are black when ripe. Mr. Miller had the ſeeds from the Cape of Good Hope, where it grows naturally, before 1756; in which year he had two plants growing in the full ground, which were killed that winter.

5. [This is a ſmall tree, with a glaucous appearance. The leaves are glanduloſe, but the glands are leſs apparent than in *C. thyoides*. The flowers are like thoſe of the firſt ſpecies; and are diſtinct from thoſe of the third, which has the ſcales of the ament pedicelled, and not peltate, as in this; two anthers (not four) under each ſcale; and two ſtigmas to each germ; whereas in this the ſtigmas are ſimple[e].]

It grows to be a large timber tree in Portugal, but in England it is not above fifteen feet high; the branches extend horizontally to a great diſtance every way, quite from the ground; they grow without much order, and the tree has a very different appearance from all the other ſorts.

[Thunberg deſcribes C. pendula of Japan to be a tree of a man's height or more, erect and ſmooth. The branches alternate, lax, leafleſs, dividing into many branchlets, which are dichotomous, filiform, long, ſpreading, lax, pendulous, covered with decuſſated, imbricate, ovate, acute leaves, ſpreading a little at the end, and very ſhort. He adds that this handſome, ſingular tree is eaſily diſtinguiſhed from all the evergreens of this order, by its abundance of very long, dichotomous, pendent branchlets.]

It is at preſent pretty rare in the Engliſh gardens, though there have been many plants raiſed here; but this ſort is not quite ſo hardy, I fear, as the common Cypreſs, for the plants are frequently killed, or greatly injured in ſevere winters; and in the hard froſt in 1740, there was a large tree of this kind entirely killed in the gardens of his Grace the Duke of Richmond, at Goodwood in Suſſex, which had been growing there ſeveral years; and in the year 1762, many large trees were killed. There are great plenty of theſe trees growing at a place called Buſaco, near Coimbra in Portugal, where this tree is called the Cedar of Buſaco; and there it grows to be a timber tree, ſo that from thence the ſeeds may be eaſily procured.

This tree grows naturally at Goa, whence it was firſt brought to Portugal, where it has ſucceeded, and been propagated; formerly there were ſome trees of this ſort growing in the Biſhop of London's

[a] Hort. kew. [b] Hunter in Evelyn. [c] Kalm. [d] Hort. kew. [e] L'Heritier.

garden at Fulham, where it paſſed under the title of Cedar of Goa, by which name it was ſent thence to the Leyden garden.

[It appears from Mr. Ray's letters (171) that this was cultivated here in 1683[a].

6. A very lofty ſtraight tree, with a trunk the thickneſs of the human thigh or more. Leaves in three or four rows, decurrent by the keel, ſubulate, bent at the end like a ſickle, marked with four furrows, ſpreading, ſmooth. Male ſpikes terminating, very many, ovate, obtuſe, ſmooth. Female ſtrobiles globular, few, ſolitary, on the lower branchlets. Scales peltate; the pelta covered at the back with a lanceolate ſcale, having ſix ſubulate teeth on the inner edge.—The wood is very ſoft, and is much uſed for cabinets and other furniture, that are varniſhed, or japanned, as we call it[b].

7. Native of New Caledonia and Norfolk iſland[c].]

PROPAGATION AND CULTURE.

Theſe trees are all propagated from ſeeds, which ſhould be ſown early in the ſpring on a bed of warm, dry, ſandy earth, which muſt be levelled very ſmooth; then ſow the ſeeds thereon pretty thick, ſifting the ſame light earth over them half an inch thick. If the weather ſhould prove very warm and dry, it will be proper to ſhade the bed from the ſun in the day-time, and water the bed, which muſt be done very carefully, obſerving not to waſh the ſeeds out of the ground. In about two months time, if your ſeeds are good, the young plants will appear above ground, which muſt be conſtantly kept clean from weeds, and in very dry weather ſhould be often refreſhed with water; but this ſhould be done with great caution, leſt you beat theſe tender rooted plants out of the ground. If the ſeeds are ſown upon a moderate hot-bed, and the beds covered with mats, they will come up much ſooner, and with greater certainty, than when they are ſown in the cold ground.

In this bed the young plants may remain two years, by which time they will have ſtrength enough to be tranſplanted into a nurſery; but while the plants are young, they are tender, and ſhould be covered in ſevere froſt with mats.

The beſt ſeaſon for removing them is in the beginning of april, when the drying eaſterly winds of march are over, and, if poſſible, chooſe a cloudy day, when it is inclinable to rain; and in taking them out of the ſeed-bed, preſerve the roots as entire as poſſible, and, if you can, a ball of earth to each plant. The ſoil in which theſe trees ſhould be planted, as I before ſaid, ſhould be, for the two firſt ſorts, a warm ſand or gravel, which, when you have prepared, by carefully digging and cleanſing from all noxious weeds, you muſt lay level. Then draw the lines where the trees are to be planted at three feet aſunder, and plant the trees at eighteen inches diſtance in the rows, obſerving to cloſe the earth well to their roots, as alſo to lay a little mulch upon the ſurface of the ground about their ſtems; and water them well to ſettle the earth to their roots, which ſhould be repeated twice a week, until the plants have taken freſh root.

Theſe plants may remain in the nurſery three or four years, according to the progreſs they make, or till your ground is ready where they are to be planted: but if you intend to let them remain longer, you ſhould take up every other tree in the rows, and tranſplant out; for otherwiſe their roots will be matted together, ſo that it will render it difficult to tranſplant them, as alſo endanger the future growth of the trees. The plants ſhould by no means be let ſtand too long in the nurſery before they are tranſplanted out for good, becauſe the roots do not mat together ſo cloſely as thoſe of many other ſorts of evergreen trees, whereby they may be taken up with good balls of earth to their roots; but the roots of the Cypreſs being apt to extend out in length, it is one of the moſt difficult trees to remove when grown large; therefore moſt curious perſons chooſe to put the young plants into ſmall pots, when they firſt take them out of the ſeed-bed, and ſo train them up in pots two or three years, until they are fit to plant out where they are to ſtand for good, and, by this management, they are ſecure of all the plants; for theſe may be ſhaken out of the pots at any time of the year without danger, and planted with their whole ball of earth, which is likewiſe a great advantage. When they are planted out for good, if they are deſigned for timber, they ſhould be planted about twelve or fourteen feet diſtance every way, and be very careful in removing thoſe in the full ground, not to ſhake the earth from their roots; to prevent which, you ſhould open the ground about each tree, cutting off all long roots, then working under the ball of earth, cut the downright roots off; and after having pared off all the earth from the upper part of the ball, as alſo reduced the bulk of it, ſo that its weight may not be too great for the fibres to ſupport, they may be carried upon a hand-barrow by two perſons to the place where they are to be planted; but if they are to be carried to a diſtant place, they ſhould either be put into baſkets, or their roots cloſely matted up. When they are planted, you muſt ſettle the earth cloſe to their roots as before, laying a little mulch upon the ſurface of the ground about their ſtems, to prevent the ſun and wind from entering the earth to dry their fibres; and water them well, to ſettle the ground to their roots, which muſt alſo be repeated, if the weather proves dry, until they have taken root, after which time they will require little more care than to keep them clear from weeds.

The upright Cypreſs (1 α) which is the moſt common ſort in England, ſeldom produces good ſeeds in this country; it is therefore the beſt way to have the cones brought over entire from the ſouth of France and Italy, where they ripen perfectly well, and take the ſeeds out juſt before you ſow them, for they will keep much better in the cones than if they are taken out. The method to get the ſeeds out is to expoſe the cones to a gentle heat, which will cauſe them to open, and eaſily emit their ſeeds.

[Dr. Hunter recommends the ground in which the ſeeds are to be ſown to be well worked, turned over, and mellowed by froſt; and if the ſoil be not naturally ſandy, to work in ſome driſt ſand all over the bed ſix inches deep: to ſow the ſeeds moderately thin, becauſe if they are ſown too thick, the roots get matted together, ſo that the plants cannot be removed out of the ſeed-bed into the nurſery without great danger. The beginning of march is the beſt time for this work.

Mr. Boutcher ſays, that if in the beginning of winter ſome ſaw-duſt is ſifted over them, it will much contribute to their preſervation in caſe of ſevere weather.

The ſpring following after ſowing, the plants, if well managed, will be ſix or ſeven inches high, and ſhould be removed and planted in rows eighteen inches aſunder, and eight or nine inches plant from plant: here they ſhould remain no more than one year, when they ought to be upwards of a foot high. The ſecond ſpring plant them in the common nurſery, in rows three feet aſunder, and eighteen inches in the row. Having ſtood in this nurſery two years, they may be removed to the place where they are to remain.

As it is no uncommon thing for a hard winter to deſtroy whole beds of theſe plants, it is neceſſary, ſays Mr. Boutcher, to provide againſt ſuch a misfortune, by ſowing ſome ſeeds in pots; which muſt be placed in a ſheltered ſituation, ſo as to receive the morning ſun till ten or eleven o'clock: keep them moderately watered, and in october remove the pots under a frame. The ſucceeding ſpring ſhake them out of theſe pots, and plant them in others of fourteen or ſixteen inches diameter, each of which will contain from ſixteen to twenty plants: place them in the ſhade till in a free-growing ſtate, and in winter remove them under a frame.]

[a] Hort. kew. [b] Thunberg. [c] Forſter.

† β. Mr. Miller affirms that the Spreading Cypreſs is rare in England, and that what has paſſed under this title here is only a variety of the common ſort, the branches of which grow much looſer; but that the true ſpreading Cypreſs extends its branches horizontally from the firſt year, and continues to extend them to a great length as the tree advances. He affirms that it is certainly a diſtinct ſpecies, grows to a much larger ſize, and that there are ſome of conſiderable ſtature in Italy.

2. The cones of the Virginian or deciduous Cypreſs may eaſily be procured from Virginia or Carolina. The ſeeds will riſe as eaſily as thoſe of the preceding ſort, and the tree is as hardy. It was formerly kept in pots, and houſed in winter; but with this management it did not ſucceed ſo well as ſince it has been planted in the full ground; and I have obſerved it to thrive beſt where it has had a moiſt ſoil. Catesby ſays, that this tree grows in places where the water commonly covers the ſurface of the ground three or four feet, ſo that it may be a very great improvement to our boggy ſoils. This tree, caſting its leaves in winter, does not ſo well ſuit with plantations of evergreens at that ſeaſon; but in ſummer it has much the appearance of an evergreen. It may alſo be propagated by cuttings, which ſhould be planted in a bed of moiſt earth in the ſpring, before they begin to ſhoot.

3. This ſort is propagated by ſeeds ſown in the ſpring in boxes or tubs filled with light freſh earth, and placed where they may enjoy the morning ſun till eleven or twelve o'clock. In dry weather they ſhould be duly watered, and conſtantly kept clear from weeds. In this ſituation they may remain till michaelmas, when they ſhould be removed to a warmer place; for the plants ſeldom appear till the following ſpring, ſo that it will be proper to place the boxes or tubs near a ſouth fence during the winter ſeaſon; leſt by being too much ſhaded, the wet ſhould rot the ſeeds. In the ſpring following, if theſe tubs or boxes are placed on a moderate hot-bed, it will bring up the plants very ſoon, and greatly forward their growth; but as the ſpring advances, they ſhould be inured to bear the open air by degrees; and in may they muſt be taken out of the hot-bed, and placed in a ſheltered ſituation, where they may enjoy the morning ſun, being careful to keep them clear from weeds, as alſo to water them duly in dry weather. The following winter it will be proper to remove the tubs near a ſouth wall or pale; for the plants being very young, are ſometimes tenderer than they will be afterward. Toward the end of march, or the beginning of april, juſt before the plants begin to ſhoot, they ſhould be carefully taken up out of the boxes; and having prepared a bed or two (according to the quantity of plants raiſed) of freſh earth in a ſheltered ſituation, the plants ſhould be planted therein in rows about eighteen inches aſunder, and about a foot diſtance plant from plant in the rows. This work ſhould be done in cloudy weather, when there is rain; for in dry weather, when eaſterly winds commonly blow at this ſeaſon, it will be very dangerous to tranſplant theſe plants; ſo that it had better be deferred a fortnight longer, till there is an alteration of the weather, than hazard the plants. When the plants are planted, they ſhould be watered to ſettle the earth to their roots; and then the ſurface of the ground ſhould be covered with mulch, to prevent the ſun and wind from penetrating to the roots of the plants; for nothing is more injurious to theſe plants, than to have their fibres dried when they are tranſplanted; therefore the plants ſhould not be taken out of the tubs till you are ready to place them in the ground, for they will not bear to lie out of the ground any time without great danger.

[In America it will not ſucceed in a dry ſoil: in a ſwampy ſoil, the branches, cut in the ſpring, will ſtrike root, and ſucceed very well.]

4. The Cape Cypreſs is too tender to thrive in the open air in England when young; but when the plants have obtained more ſtrength, it is very probable they may do well in warm ſituations. Young plants placed under a frame which had no glaſs, but only wooden ſhutters, were not injured by the cold, though the earth of the pots was frequently frozen hard. [The practice now is, to keep them in pots, and houſe them in winter till they are a yard in height. When they are committed to the open air, they muſt have a dry warm ſoil, and a well-ſheltered ſituation: nothing, however, can enſure them but the dry ſtove.]

5. This ſort may be propagated from ſeeds in the ſame manner as the common Cypreſs, and the plants ſhould be treated in the ſame manner as has been directed for them, with this difference only, that it will be proper to cover theſe plants during the two firſt winters after they are come up, eſpecially if the froſt ſhould be ſevere, which might deſtroy them, if they are expoſed to it while they are young. This ſort may alſo be propagated by cuttings, which, if planted in autumn, and ſcreened in winter, will take root; but it is generally two years before they will be rooted enough to tranſplant, nor will the plants ſo raiſed thrive ſo faſt as the ſeedlings; therefore, when the ſeeds can be obtained, that is the beſt method to propagate this tree.

SPECIES.

1. Curculigo orchioides.
Plant. coromand. 14. *t.* 13. *Gærtn. fruct.* 1. 63.

DESCRIPTION, *&c.*

Root tuberous, with many fleſhy vermicular fibres. Leaves numerous, all radical, petioled, ſword-form, nerved, ſlender, with a very few ſoft white hairs on them when young, from ſix to eighteen inches long, half or three quarters of an inch broad: petiole channelled, below ſheath-form, embracing thoſe within. Raceme ſolitary, axillary, two-ranked, its apex juſt appearing above the earth. Peduncle compreſſed, clubbed, about an inch long. Bractes below remote, above nearer, ſpathe-like, pointed, decreaſing in length towards the top, ſo that their apexes are nearly horizontal, like a corymb, one-flowered. Flowers pretty large, yellow: the one or two lowermoſt hermaphrodite; above all male. Peduncle ſo long as to elevate the flower above the earth above one inch, hairy, three-ſided. When the ſeeds are ripe, their number is only from one to four, and they ſeem as if in a tranſparent, fleſhy, one-celled capſule, and are ſeparated by a ſpongy fleſhy ſubſtance.

Native of ſhady uncultivated places about Samulcotah, but by no means common. It is the Nallatady of the Telingas[*].

Gærtner remarks, that this plant differs from all others in the ſingular ſtructure of the ſtyle and capſule, and the roundiſh horny proceſs from the outer and upper part of the ſeed, thickening upwards, and ſlightly incurved, ſo as to reſemble the beak of a Curculio, whence he gave it the name.

Bulbs knotted, ſcape long, bracted.

DESCRIPTION, *&c.*

1. Root perennial, with a large ovate bulb, frequently as big as a gooſe's egg, covered with a thin rufeſcent pellicle, that has parallel, rooting rings, within ſolid, fleſhy, reddiſh yellow, of a bitteriſh taſte, and ſlightly aromatic ſmell.

It creeps under ground by means of little bulbs of the ſame ovate form, growing by the ſide of the maternal bulb. Stem none. Leaves annual, three feet high, upright, broad-lanceolate, bluntiſh, ſmooth, bright green, grooved, with a few oblique lines; petioles ſhort, dilated at the baſe, embracing the inner ones, and reſembling a thick ſtem[*]. From the middle of theſe ariſes the flower-ſtalk, ſupporting a looſe ſpike of flowers of a pale yellowiſh colour, incloſed in ſeveral ſpathes or ſheaths which drop off.

Native of the Eaſt-Indies, the mountains of China, Cochinchina, &c.

Cultivated by Mr. Miller before 1759.

2. Root perennial, creeping, fleſhy, palmate, with columnar branches, and parallel rooting rings, the ſkin thin and pale, the fleſh ſaffron-coloured, with a bitteriſh taſte, and a ſmell of ſalve. Stem none. Leaves broad-lanceolate, large, quite entire, ſmooth, annual, pale green, grooved, with oblique, ſlender, frequent lines: petioles long, upright, dilated at the baſe, mutually ſupporting and embracing each other. Scape external, ſlender, nearly erect, almoſt naked, approximating to the bundle of leaves. Spike thick, ſubovate, three inches long. Flowers ſeſſile, white, with a yellow nectary, ſolitary, and incloſed within the ſcales of the ſpike. *Calyx* ſuperior, bifid: clefts oblong-ovate, erect, hid within the ſcales of the ſpike. *Corolla* one-petalled, funnel-ſhaped: tube ſlender, equal to the calyx, widening above; border four-parted, the ſegments nearly equal in length, the two lateral ones blunt, waved, and plaited, the upper one acute and bent in, the lower broader, bifid, with the ſegments rounded. Nectary large, bent in, three-lobed, with the middle lobe emarginate, faſtened at bottom to the outer ſegment of the corolla. *Filament* broad and flat, ſhort, rounded at the top, placed on the upper ſegment of the corolla: anther ſomewhat cubical, bifid, with an awl-ſhaped proceſs on each ſide. *Germ* roundiſh: ſtyle capillary, equal to the ſtamen, incloſed within the notch of the anther: ſtigma concave. *Capſule* roundiſh, ſmooth and even, three-celled, three-valved. *Seeds* round, few.—It has no barren filaments[*].

The fructification is thus deſcribed by Retzius. A ſingle ſpike comes forth from the laſt ſheaths of the leaves; it is peduncled, erect, club-ſhaped, ſquarroſe, ſcarcely a foot in length, ſhorter than the leaves, covered with imbricate, ovate, concave bractes; below the middle connected by the back, recurved, ſpreading, acute, margined, veiny-ſtreaked, whitiſh green; at the end the bractes are barren, narrower, wavy-ſinuoſe, and of a paler colour. There are commonly three flowers within each bracte, ſometimes more, involucred. The involucre is two-leaved. The calyx is one-leafed, tubular, a little inflated, obtuſe, toothletted, membranaceous, ſemipellucid, divided on one ſide to the middle, half the length of the tube of the corolla, which is erect, or a little bent in, round, ſmooth, ſtiffiſh, white, above the middle bell-ſhaped, ſomewhat compreſſed, keeled at the back; border double, each three-parted. Filament ſingle, erect, lanceolate-ovate, between the two dorſal ſegments growing to the dorſal border, flattiſh, ſomewhat convex in front, marked with a line behind, half the length of the approximating ſegments, ſtiffer than they, but of the ſame colour. Germ hairy: ſtyle between the nectaries, erect, white, ſmooth, in

* Loureiro. * Ibid.

the

the groove of the anther: ſtigma club-ſhaped, obtuſe, concave, four-toothed, white. Nectaries two, within the tube, ſitting on the germ, erect, cylindric, half ſurrounding the ſtyle, hardly the length of the germ.

Native of the Eaſt Indies, China, Cochinchina, &c. It is cultivated by the Chineſe in their gardens, and very abundantly at Malacca. It very ſeldom produces ſeed.

Cultivated by Mr. Miller, before 1759.

Swartz joins this Curcuma with the genus Amomum.

It was much uſed formerly in cookery to give things a colour; it is ſtill uſed in the Eaſt for this purpoſe and for dyeing.

The root of this plant has had the reputation of being a powerful aperient and reſolvent. It has been commonly preſcribed in obſtructions of the liver, and other chronic complaints. The diſeaſe in which it has been thought to be moſt efficacious is the jaundice. It is however now very rarely employed in Europe. The general doſe is ſubſtance is from a ſcruple to a drachm. It tinges the urine of a deep yellow colour. In the Eaſt Turmeric is yet in high reputation. The firſt ſpecies is ſtronger, and ſeldom given there internally; externally applied as a cataplaſm, with the root of Crinum zeylanicum and the leaves of Artemiſia, it is eſteemed a ſovereign remedy in ſwellings of the abdomen ariſing from a ſuppreſſion of the menſes.

3. This is an annual plant, without any ſtem, upright, three feet high. Root perennial, horizontal, creeping, oblong, columnar, twiſted and knotty, within and without pale, fleſhy, with little ſmell or taſte. Leaves lanceolate, large, with ſeveral oblique ſlender grooves: petioles dilated at the baſe, embracing the inner ones. Scape external, eight inches long, clothed with ſhort bractes. Spike oblong, with ovate-lanceolate, looſe, reflex, reddiſh, one-flowered ſcales. Corolla yelloviſh white, four-parted, with a three-lobed nectary. Stamen one, fertile, without any barren ones. Capſule inferior, three-celled, three-valved, many-ſeeded.

Native of China about Canton, and Cochinchina.]

PROPAGATION AND CULTURE.

Theſe plants muſt be placed in the bark-ſtove. They are only propagated by parting their roots, in the ſpring, before they put out new leaves. Plant them in rich kitchen-garden earth, and keep the pots conſtantly plunged in the bark-bed. In ſummer, when the plants are in a growing ſtate, refreſh them frequently with water, but not in large quantities; and admit a large ſhare of air to them in warm weather. When the leaves are decayed they ſhould have very little wet, and ſhould be kept in a warm temperature. They uſually flower in auguſt; but ſtrong roots only produce flowers.

DESCRIPTION, &c.

This is one of the largeſt trees in the African woods, with very diminutive flowers. The Hottentots and Caffres make the ſhafts of their javelins or aſſagays from the wood of this tree. They always carry one or two of theſe with them, on their journies. They conſiſt of an iron ſpear hollowed out on each ſide about ſix inches long, with or without an iron ſhaft, which is ſometimes round and ſmooth, and ſometimes grooved. It is faſtened with thongs of leather to a ſlender round ſtick, five feet long, tapering towards the end, and made of this wood. With theſe lances, which they throw with great dexterity to the diſtance of a hundred paces, the Hottentots and Caffres defend themſelves, and kill buffaloes and other wild animals.

This tree is called in Dutch *Witte-eſſe, Stinkhout,* and *Aſſagay-bout**; in Engliſh *Haſſagay* or *Aſſagay-tree*, from its uſe among the natives of the Cape of Good Hope.

It was introduced here in 1775, by Mr. Francis Maſſon†.

DESCRIPTIONS, *&c.*

Theſe are paraſitical plants, faſtening themſelves to, and drawing their nouriſhment from others. The ſeed does not ſplit into lobes, but opens and puts forth a little ſpiral body, which is the embryo: the ſtalk twines about ſome other plant, contrary to the ſun's apparent motion, or from right to left; ſending out from the inner ſurface a number of little veſicles, which attach themſelves to the bark of the plant: by degrees, the longitudinal veſſels of the ſtalk ſhoot from their extremities, and inſinuate themſelves ſo intimately with it, that it is eaſier to break than to diſengage them from it. They have no leaves, except here and there a very ſmall membranaceous ſcale, cloſe under a branch.—Linneus aſſerts that theſe plants deſert the ground entirely; and from the experiments made by Parkinſon and Ray it appears, that plants raiſed from ſeed ſoon die, when they have no plant to which they can attach themſelves. They adhere to the ground by the original root, and draw a part of their nutriment from thence, at firſt; but the original root withers away as ſoon as the young ſtem has fixed itſelf to any other plant.

1. Stem ſlender, filiform, ſmooth, four-cornered, reddiſh. A ſingle ſmall ovate acute ſcale under each ball of flowers; where alſo it frequently puts forth a branch: theſe balls or globular heads do not ſurround the ſtem, but proceed from the ſide where it divides into branches; and have eighteen flowers or more. Calyx and corolla uſually four-cleft, but ſometimes five-cleft: the former ſhaped like a ſpice clove, running down, as it were, into a kind of peduncle; the ſegments ovate, often rounded at the end. Corolla white, or with a tinge of purple. Scarcely any nectaries in the primary flowers, but in the later ones ſemibifid. Stamens four or five; anthers yellow. Stigma reddiſh. Capſule membranaceous, tranſparent, ſmall, immerſed almoſt half way in the fleſhy calyx, cut cloſe to the baſe, or below the middle, the partition riſing from the lower half. Seeds generally two in each cell, but ſometimes three or four[a]; they are almoſt globular, covered with very minute raiſed dots, and of a yellow bay colour. Gærtner obſerves, that the embryo is filiform, one-lobed, yellow, and that it makes three revolutions round the albumen.

Native of Europe, in hedges, *&c.* uſually on buſhes and the loftier plants, as Hops, Brambles, woody Nightſhade, Fern, Thiſtles, Hemp; alſo on Flax, Nettles, Clover, Graſs, *&c.* Flowering in july and auguſt.

2. This, which is ſuppoſed by many to be ours, has been thought by Linneus and others to be only a variety of the foregoing. It is certainly very like it, but differs in having all the parts ſmaller and more tender, the ſtems more ſlender. The calyx between cloven and divided, with the ſegments ovate, acuminate, unequal, not running down into a kind of peduncle. Corolla paler, deeper cut; the ſegments ſharper and ſmaller: the balls of flowers cloſer[b].

[a] Leers, Pollich, Krocker, Stokes in Withering.
[b] Stokes in Withering. Krocker.

In cultivated fields, particularly among pulſe; alſo on heaths. I have obſerved it particularly on Beans, Nettles, and Heath. Others have remarked it on Furze, Flax; Thyme, wild Thyme, Lavender, and others of the Didynamia claſs; Spurge, Hops, Graſs, *&c.* It flowers from june to auguſt. Both are annual.—From its deſtructive quality of ſuffocating plants, it has the opprobrious names of *Hell-weed* and *Devil's-guts.* The other name is from the German *Dotter.*

Dr. Smith has no doubt but that the firſt ſpecies is our plant: and Monſ. Villars is decidedly of opinion that they differ only in ſize.

3. This is a very branching, leafleſs, twining, paraſitical plant; tender, ſhining, and yellowiſh. Common peduncles very ſhort. Flowers ſmall, without ſcent, aggregate, yellowiſh or greeniſh. Calyx withering. Seeds two, three, or only one arriving at maturity, the reſt being abortive. The calyx is five-cleft, the ſegments roundiſh, blunt, concave, ſhort, converging; that and the corolla both of the ſame colour. Petal cylindric, erect; tube the length of the calyx; border five-cleft, ſmall, ſpreading. Nectary of five fringed, converging ſcales, faſtened to the petal below the ſtamens. Filaments always five, upright, from the upper part of the tube, the length of the corolla: anthers oblong, erect. Styles little longer than the corolla: ſtigmas capitate. Capſule one-celled, opening in two parts horizontally. Seeds few, convex on one ſide, flattiſh on the other[a]: according to Swartz roundiſh, and four in each capſule.

Native of America, on ſhrubs and trees, and in hedges: according to Brown, creeping on the graſs and lower buſhes.—Sloane ſays the ſtems are very long and ſtrong, ſtretching themſelves over very large trees, and whole fields and paſtures.

4. This ſpecies alſo climbs trees. Stem round, branching, very thick like hop-binds; bark reddiſh green or brown purple, rough and ſtudded with purpliſh, ſtiff, riſing grains like Millet. Flowers on racemes coming out laterally, an inch or two in length, ſometimes branched; they are ſcattered, ſolitary, or only two or three together, not glomerate; ſeſſile, not peduncled. Corolla four-cleft, reddiſh white. Calyx covered with a fleſhy ſkin, green, or tinged with purple. Capſule large, covered with the ſame ſkin. Seeds wrinkled, rounded.

Native of Sileſia, flowering in july and auguſt. Annual[b].

CUSCUTA. See *Baſella, Caſſyta,* and *Tillandſia.*

CUSPIDIA. See *Gorteria.*

CUSSONIA. *(In memory of Caſſon, a celebrated botaniſt, who laboured to complete the claſs of umbellate plants. Lin. ſuppl.)*
Lin. ſuppl. 25. *n.* 1378. *Schreb.* 455. *Thunb. nov. act. upſ.* 3. 211. *nov. gen.* 10. *Juſſ.* 218.

Claſſ. 5. 2. Pentandria Digynia.

Nat. order of *Aralie.* Juſſieu.

GENERIC CHARACTER.

CAL. *Umbel* none (but three or more peduncles, umbelled, collecting the flowers into a raceme or ſpike.)
Involucre none (but ſcattered bractes at the baſe of the peduncles.)
Perianth one-leafed, truncate, obſcurely five-toothed, ſhorter than the corolla, permanent.

COR. *Petals* five, oblong, acute.

STAM. *Filaments* five, very ſhort. *Anthers* ovate.

PIST. *Germ* inferior, turbinate. *Styles* two, filiform, patulous. *Stigmas* ſimple, obtuſe.

PER. twin, compreſſed, angular, crowned with the calyx and ſtyles, two-celled, two-valved.

SEEDS ſolitary.

ESSENTIAL CHARACTER.

Pet. three-cornered. Margin of the receptacle dilated into a five-toothed calyx.

SPECIES.

1. Cuſſonia thyrſiflora.
Lin. ſyſt. 292. *ſuppl.* 182. *Thunb. act. upſ.* 3. *t.* 12.

[a] Jacquin. [b] Krocker.

Leaves digitate, leaflets ſeſſile wedge-form truncate three-toothed; flowers racemed.

2. Cuſſonia ſpicata.
Lin. ſyſt. 292. *ſuppl.* 182. *Thunb. act. upſ.* 3. *t.* 13.

Leaves digitate, leaflets petioled ſpatulate; ligule three or five-palmate finely ſerrate; flowers in ſpikes.

DESCRIPTIONS, *&c.*

1. Stem fruteſcent; at bottom ſcabrous, unequal, ſimple, the thickneſs of a finger; very ſimple at top. Leaves at the top of the ſtem, approximating, alternate, petioled, digitated in fives, Leaflets unequal, ſcarcely emarginate, with three and ſometimes five remote, obtuſe, ſmall teeth; they have the conſiſtence of Menyanthes leaves. Petioles long. Stipules between the leaves. Racemes terminating, umbelled. Rays four, very ſimple, naked below, but with racemed flowers at the end, the raceme cylindric.—There is a variety of this with jointed leaflets, the loweſt joint dilated at the end into ſmaller lobes, whence the leaflets are as it were proliferous.

2. This and the foregoing are natives of the Cape of Good Hope[a].

Juſſieu regards this genus as ſcarcely diſtinct from *Panax*. If it is to be preſerved, the ſhrubby *Panaces* ſhould be referred to it; P. undulata of Aublet, *guian. t.* 360.; Unjala, *Rheede malab.* 7. *t.* 28; and perhaps Aralia umbellifera of Lamarck.

Leaves waved; branches ſpreading very much.

[3. Cyanella alba. *White-flowered Cyanella.*
Lin. ſyſt. 329. *ſuppl.* 201.
Leaves linear-ſubform.

DESCRIPTIONS, *&c.*

1. This agrees with the next ſpecies in having the filaments at the baſe in form of a pitcher, in having one anther larger than the reſt, and a ſimple ſtigma. It differs in having the root-leaves lanceolate not linear, the peduncles leſs divaricate, the petals larger and yellow. It was found at the Cape of Good Hope by Sparrmann[b]. And was introduced in 1788, by Mr. Francis Maſſon. It flowers in july[c].]

2. The root is ſhaped like that of the Spring Crocus; leaves long, narrow, with a groove on their upper ſide; the peduncle ariſes immediately from the root, ſupporting one flower of a fine blue colour, which appears in may, but the flowers are not ſucceeded by ſeeds in England.

[It has the ſtature of Scilla. Flowers irregular[d]. Capſule rounded-three-cornered, netted with obſcure nerves. Seeds erect, fixed in a double row to the central margin of the partitions; there are four in each cell, of a ſubovate form, narrowed downwards, variouſly angular, very dark brown[e].

Native of the Cape of Good Hope. Cultivated by Mr. Miller in 1768.

They eat the roots roaſted in Africa.

3. Found at the Cape by Thunberg[f].]

PROPAGATION AND CULTURE.

The roots ſhould be planted in pots filled with light earth, placed in winter in a frame, and treated in the ſame manner as is directed for Ixia.

DESCRIPTIONS, *&c.*

1. This plant was at firſt placed by Linnæus among the Palms, with an obſervation, that the foliation reſembled that of the Ferns, to which tribe he afterwards removed it, obſerving that it had naked pollen, without any anther. Jacquin however, (Acta Helv. 8. p. 59. t. 2.) has ſhewn that

[a] Linn. ſuppl. [b] Ibid. [c] Hort. kew. [d] Linn. ſpec. [e] Gærtner. [f] Linn. ſuppl.

it

it is a perfect dioecous plant, and has in part described and figured the parts of fructification: by which it appears after all to be a Palm.

Native of the East Indies, the Friendly Islands, and the New Hebrides in the South Seas. Introduced about 1763, by John Blackburne, Esq.[a]

2. Trunk round, branched, a fathom or more in height, the thickness of the thigh, ferruginous and hirsute from the falling of the leaves. The stipe of the fronds has spines below. The leaflets are nearly opposite, linear, somewhat sickle-shaped towards the inside, ending in a simple spine, entire, with the edge rolled back, and an elevated line along the middle, smooth, two lines broad, from erect spreading, the lowest and highest shorter than the others. The fruit is an ovate, flat, red drupe, an inch and half in length[b].

Whether the *Cycas inermis* of Loureiro be the same with the *C. revoluta* of Thunberg, I dare not determine. According to his description, the trunk is five feet high, quite single or undivided, the thickness of the human thigh, rugged and brown. Fronds five feet long, ascending: the stipes roundish and without any spines: the leaflets linear-lanceolate, six inches long, smooth, dusky-green, flattish, opposite, sessile. Male ament terminating, erect, solitary, oval-oblong, four inches in diameter, strobile-form, dusky yellow, imbricate, almost closed: scales oblong-turbinate, thick, fungose, staminiferous. No perianth, corolla, or filaments. Anthers more than a hundred in each scale, scattered, globular, as big as the seeds of Radish, opening at the tip. Female flower, with spadixes various, linear, reflex, few-flowered, subterminating, simple, terminated by a jagged bracte. Drupe an inch and half in diameter, ovate, a little compressed, smooth and even, rufous; including a woody nut of the same form, in which is a single kernel. It is never branched, nor monoecous.

It is not used for food in China or Cochinchina, but it is cultivated there for its beauty. In Tunquin they make a sort of bread called *Saga* from the pith of the trunk[c].

The fruit is eaten by the Japonese: but the pith of the trunk is most esteemed for its highly nutritive quality: they affirm that a soldier can subsist upon a very small piece of it, and therefore it is made a capital offence to export this tree[d].

Native also of China and Cochinchina, and introduced about 1758] by Richard Warner, Esq. of Woodford in Essex, who received a plant from Captain Hutchinson. His ship being attacked by the French, the head of the plant was shot off, but the stem being preserved, produced several heads, which being taken off produced as many plants.

Dampier says that the Sago-trees are called by the natives of Mindanao, (one of the Philippine islands) *Ishly-trees*; that they grow wild in great groves of five or six miles long, by the sides of the rivers. Its body and shape is much like the Palmeto-tree, or the Cabbage-tree, but not so tall as the latter. The wood is full of white pith like that of Elder. They cut down the tree, split it in the middle, and scrape out all the pith: which they beat lustily with a wooden pestle in a great mortar or trough, and then put it into a cloth or strainer held over a trough; and pouring water in among it, they stir it about: so the water carries all the substance of the pith through the cloth into the trough, leaving behind a light sort of husk, which they throw away: that which runs into the trough settles to the bottom like mud; then they draw off the water, and make the substance into cakes, which being baked proves very good bread. The Mindanao people live three or four months of the year on this food. The native Indians of Ternate, Tidore, and all the Spice islands have plenty of these trees, and use them for food. The Sago which is transported into other parts of the East Indies, is dried in small pieces like little seeds or comfits, and commonly eaten with milk of Almonds by those that are troubled with the flux.]

[a] Hort. kew. [b] Thunberg. [c] Loureiro. [d] Thunberg.

PROPAGATION AND CULTURE.

These trees require to be plunged in the bark-bed in the stove, which should be kept up full to temperate heat in winter; but in summer should be much hotter. They should be frequently refreshed with water during hot weather; but in autumn and winter it should be given sparingly.

DESCRIPTION, *&c.*

The flowers are borne singly on a naked stem, peduncle or scape, and are nodding. The root is roundish, solid and tuberous.

Linneus observes, that the several varieties connect the plants which have angular leaves with those which have round ones so intimately, that limits are assigned to them with difficulty.

Mr. Curtis is of opinion, that Linneus, in having only two species, makes too few; and that Miller,

on the contrary, in giving eight ſpecies, is perhaps too profuſe. I have followed the Kew catalogue.—Of the ſix ſpecies ſet down by Mr. Miller, for he has no more than ſix: the fourth I have put down as a variety of our third, though the leaves be entire. The ſecond appears not to be different from our firſt. Perhaps the fifth is a variety of the ſame ſpecies. I know not whether any one of Miller's ſpecies anſwers to the *europæum* of Linneus, figured by Jacquin.—Parkinſon has enumerated ten ſorts, ſeveral of which are mere varieties.]

Mr. Miller gives what he takes to be varieties, from many years obſervation and experience in ſowing the ſeeds. C. hederæ folio, *Baub. pin.* which is the moſt common in England, produces two varieties, with purple, and white flowers. C. coum does not vary. C. perſicum, varies with a white flower and purple bottom, and a pale flower with a deeper coloured bottom; ſome plants alſo have rounder leaves than others. C. verno tempore florens, *Cluſ. hiſt.* 265. which is the laſt common among us of any, he will have to be a diſtinct ſpecies. As alſo C. radice anemones, flore purpureo minore odorato, *Boerh. ind.*; which he ſays differs entirely in the form of the root, and the ſize of the leaves and flowers, from all the reſt.

1. This has plane orbicular leaves, with ſhort weak petioles, their under ſide is very red in the beginning of winter, but that colour goes off in the ſpring; their upper ſide is ſmooth, of a lucid green, and ſpread flat open; whereas the other ſorts are hollowed, and reflex at the baſe. The flowers are very bright purple, and appearing in the middle of winter when there are few other flowers, this plant is the more valuable.

C. purpuraſcens, n. 2. of Miller, may perhaps be a variety of this. The leaves are large, orbicular, and heart-ſhaped at their baſe, of a purple colour on their under ſide. The leaves and flowers come up from the root at the ſame time: the latter are of a purpliſh colour, and their bottoms of a deep red. It flowers late in autumn, and is rare in England. It requires protection in winter.

C. orbiculatum, n. 5. of Miller, may probably be another variety. It has a ſmall irregular root, not larger than a nutmeg: the leaves are orbicular and ſmall: the flowers ſmall, fleſh-coloured with purple bottoms. They appear in autumn, but rarely produce ſeeds in England.

[Native of the South of Europe. Cultivated 1731[a].

2. Root tuberous, oblately ſpheroidal, white within, brown without. Hence proceeds, within the ground, a very ſhort ſtem, and from that the leaves and one-flowered peduncles or ſcapes. Leaves kidney-form roundiſh, very blunt, ſlightly crenulate, deep green and ſpotted above, beneath commonly red-purple, ſmooth, on very long round red petioles. Peduncles like the petioles, erect in the flower, ſpiral in the fruit. Flowers drooping, ſweet-ſcented, purple. Capſule coriaceous, purple, opening firſt at the top, and then entirely. Seeds large, ruſous, kidney-form[b].

Native of Auſtria. Cultivated 1596, by Gerarde[c].]

3. Leaves ſtiff, on ſtrong fleſhy petioles, near ſix inches long, of a purple colour, as are alſo the veins of the leaves underneath; but the upper ſide is veined and marbled with white. The corolla is pure white with a bright purple bottom; but it varies in colour, and is ſometimes entirely white: this variety ſmells very ſweet. The petal of the Perſian Cyclamen is divided into nine ſegments to the bottom: theſe ſegments are twiſted and bent back like the others. It flowers in march and april, and the ſeeds ripen in auguſt.

[Cultivated 1731, by Mr. Miller[d].

By its name it ſhould be a native of Perſia; according to Mr. Curtis, it comes from the Eaſt Indies; and from the Kew catalogue we learn, that it was found by Dr. John Sibthorp in the iſland of Cyprus.

It flowers early in the ſpring, and is admirably adapted to decorate the parlour or ſtudy. It varies with fragrant flowers; and with the eye more or leſs red[e].]

β. The vernal Cyclamen of Miller, n. 4. has large, angular, heart-ſhaped leaves, entire about the edges; they are veined and marbled with white on the upper ſide, and ſtand upon pretty long petioles: the flowers are large, of a pale purple colour, with a bright red or purple bottom. They appear in march and april, and the ſeeds ripen in auguſt. It is commonly called Perſian Cyclamen.

4. Root large, orbicular, compreſſed. Leaves numerous on petioles ſix or ſeven inches long; the leaves are marked with black in the middle: the flowers appear before them on long fleſhy ſcapes, in auguſt or ſeptember. Soon after, the leaves come out, continue growing all the winter and ſpring till may, when they begin to decay; in june they are entirely dried up. After the flowers are fallen, the peduncles twiſt up like a ſcrew, incloſing the germ in the centre, and lie cloſe to the ground among the leaves, which ſerve as a protection to the ſeed, which ripens in june. There are two varieties of this; one with a white, and the other with a purpliſh flower.

Native of Italy. [Cultivated by Gerarde, in 1596[f].

Ray found it in the neighbourhood of Rome abundantly, flowering in ſeptember.

5. Undoubtedly a ſpecies of Cyclamen, as the root, cordate crenate leaves, flowers and ſcapes abundantly prove. It differs only in having the diviſions of the corolla not reflected but hanging down; and the whole corolla being much larger than in the European ſpecies.—Native of the iſland of Ceylon[g].

PROPAGATION AND CULTURE.

All the ſorts are propagated by ſeeds which ſhould be ſown ſoon after they are ripe, in boxes or pots filled with light kitchen-garden earth, mixed with a little ſand, and covered about half an inch deep, placing them where they may have only the morning ſun till the beginning of ſeptember, when they may be removed to a warmer expoſure. Thoſe of the firſt, ſecond, and fourth ſorts may be plunged into the ground cloſe to a ſouth wall, a pale, or reed hedge, in october, where, if it ſhould be very ſevere froſt, it will be proper to cover them either with mats or peaſe-haulm, but in common winters they will not require any covering. The pots or tubs in which the Perſian ſort is ſown, ſhould then be placed under a common hot-bed frame, where they may be protected from froſt and hard rains, but in mild weather the glaſſes may be taken off every day to admit freſh air to them. The fourth ſort will come up about Chriſtmas, if the ſeed were ſown in auguſt, and their leaves will continue green till may; and thoſe of the Perſian ſort will come up early in the ſpring, and continue green till june, when they will begin to decay; then they ſhould be removed to an eaſt aſpect, where they will have only the morning ſun, in which ſituation they may remain till the middle of auguſt; during which time they ſhould have very little water, for then the roots are in an inactive ſtate, when much wet will rot them. The pots and tubs in which they are ſown, muſt be conſtantly kept clean from weeds; for if the weeds are permitted to grow, their roots will cloſely entangle with thoſe of the Cyclamen, ſo that in pulling out the weeds, the other roots will be drawn out with them. In the beginning of october, there ſhould be ſome freſh earth ſpread over the tubs or pots, which ſhould be removed again into ſhelter, in the ſame manner as before; and the following ſummer they muſt be managed alſo in the ſame way till their leaves decay, when they ſhould be carefully taken up, and thoſe of the firſt, ſecond, and fourth

[a] Hort. kew. [b] Jacquin. [c] Hort. kew. [d] Ibid. [e] Curtis. [f] Hort. kew. [g] Linn. syſt.

ſorts

ſorts placed in a warm border at three or four inches diſtance, but the other ſort muſt be planted in pots to be ſheltered in winter.

The Perſian ſort is more impatient of cold and wet than the others; this muſt conſtantly be preſerved in pots filled with ſandy light earth, or a mixture of loam and lime rubbiſh, and houſed in winter, but ſhould be placed near the glaſſes, where the plants may enjoy as much free open air as poſſible, when the weather will permit; for if they are crowded under other plants, and are kept too cloſe, they are very ſubject to mould and rot; nor ſhould they have much water in winter, which is alſo very injurious to them, but whenever they want water, it ſhould be given them ſparingly. In ſummer theſe plants may be expoſed to the open air, when their green leaves will decay; at which time you ſhould remove them to a place, where they may have the morning ſun until eleven o'clock; but during the time that the roots are deſtitute of leaves, they ſhould have very little water given them, becauſe at that ſeaſon they are not capable of diſcharging the moiſture. This is alſo the proper ſeaſon to tranſplant the roots, or to freſh earth them; and as the autumn comes on, that the heat decreaſes, they may be removed into places more expoſed to the ſun, where they may remain until october before they need be houſed.

Toward Chriſtmas, if the roots are in good health, the firſt ſort will begin to flower, and continue producing freſh flowers till the middle of february, and theſe will be ſucceeded by the Perſian ſorts, which continue till may; but if you intend to have any ſeeds, you muſt let the pots be placed ſo as to receive a great ſhare of freſh air, for if their flowers are drawn up in the houſe, they ſeldom produce any ſeeds. Theſe ſeeds are ripe about july, when they ſhould be immediately ſown in pots or caſes of good light undunged earth, which ſhould be ſheltered in winter under a frame, and expoſed in ſummer in the ſame manner as is directed for the older roots, obſerving to remove them into pots at a wider diſtance when they are two years old, and ſo from time to time, as their roots increaſe in bulk, you muſt give them more room; and in about four or five years they will begin to flower, when each root ſhould have a ſeparate ſmall pot, and when it is grown large, a larger.

When the firſt ſort is planted in an open border, common hot-bed frames ſhould be placed over it in winter, to protect it from froſt. Thus managed, it will produce more and fairer flowers than when planted in a pot, and good ſeeds may be expected from it. Perſons who are curious in flowers ſhould have a border framed over, on purpoſe for theſe, the Guernſey and Belladonna Lillies, with other curious bulbous roots.

[CYCLAS. (Κυκλας, *adverb. orbiculato, rotunda, circular.* Κυκλαδες νησοι, *the iſlands called Cyclades; from their lying in a circle.—This plant has its name from the orbicular ſeeing ſurrounding the pericarp.*)

Lin. gen. 366. *Schreb. n.* 512. Apalatoa. *Aubl.* t. 147. Touchiroa. *Aubl.* 148. *Juſſ.* 365.

* Claſſ. 10. 1. Decandria Monogynia.

Nat. order of *Lomentaceæ*. *Leguminoſæ* Juſſ.

GENERIC CHARACTER.

Cal. *Perianth* one-leafed. *Tube* ſhort, turbinate: *border* four-parted, patulous; *ſegments* ovate-oblong, acute.

Cor. none.

Stam. *Filaments* ten, capillary, inſerted into the neck of the calyx, and longer. *Anthers* ovate.

Pist. *Germ* ovate-oblong, villoſe, pedicelled. *Style* capillary, flexuoſe. *Stigma* obtuſe.

Per. Legume? roundiſh, depreſſed, wrinkled, ſurrounded by an orbicular, membranaceous, broad, waving wing, one-celled, not opening.

Seed ſingle, kidney-form.

ESSENTIAL CHARACTER.

Cal. four-parted, ſpreading, with a ſhort turbinate tube. *Cor.* none. *Filaments* inſerted into the neck of the calyx. *Style* flexuoſe. *Legume* roundiſh, winged, one-ſeeded.

SPECIES.

1. Cyclas ſpicata.
   Apalatoa ſpicata. *Aubl. guian.* 382. *t.* 147. *Leaves pinnate.*
2. Cyclas aromatica.
   Touchiroa aromatica. *Aubl. guian.* 384. *t.* 148. *Leaves ovate.*

DESCRIPTION, *&c.*

1. The trunk of this tree is from thirty to forty feet high, and a foot and half in diameter. The bark is gray and ſmooth; the wood whitiſh. It has ſeveral large boughs at top, ſpreading in all directions. Leaves alternate, unequally pinnate. Leaflets alternate, ſeven on each ſide, ovate-oblong, acuminate, ſmooth, quite entire, ſubſeſſile, firm, unequal, the largeſt four inches long, and an inch and half wide. Stipules in pairs at the baſe of the common petiole, deciduous. Flowers in long ſpikes, axillary and terminating, on ſhort pedicels. Bracte at the baſe of the peduncle, and of each pedicel.

   Native of the great foreſts of Guiana, flowering there in november, and fruiting in january. The Caribee name is Apalatoua.

2. The trunk of this tree is from forty to fifty feet high and more, and about two feet in diameter. Bark gray: wood white and not compact. Branches very numerous ſpreading in every direction. Leaves alternate, large, ſtiff, ovate, acute, ſmooth, quite entire, on ſhort petioles, at the baſe of which are two deciduous ſtipules. Spikes axillary, covered with herbaceous flowers.

   Native of the great foreſts of Guiana, in marſhy places. It flowers there in december, and bears fruit in may.

   The Caribee name is Moutouchiraou.—The wood is light and a little aromatic.

Cydonia. See *Cratægus* and *Pyrus*.

CYLISTA. (*From* κυλιω, *volvo, cumes* κυλιστος, *convolutus, volubilis; twining.*)

Ait. hort. kew. 3. 312. *Schreb. n.* 1759.

Claſſ. 17. 4. Diadelphia Decandria.

Nat. order of *Papilionaceæ* or *Leguminoſæ*.

GENERIC CHARACTER.

Cal. *Perianth* one-leafed, four-parted, very large, permanent: the upper diviſion reflex, bifid; the reſt erect, oblong, acute.

Cor. papilionaceous, a little longer than the calyx, permanent.

   Banner roundiſh, emarginate, with a ſmall lobe on each ſide of the baſe.

   Wings oblong, obtuſe, ſhorter than the banner, with a proceſs on each ſide of the baſe.

   Keel oblong, cleft at top and bottom, longer than the wings.

Stam. *Filaments* diadelphous (ſimple and nine-cleft) aſcending. *Anthers* roundiſh.

Pist. *Germ* ſuperior, ovate, compreſſed. *Style* ſubulate, aſcending. *Stigma* ſubcapitate.

Per. *Legume* ovate-oblong, compreſſed, one-celled.

Seeds two, oval.

ESSENTIAL CHARACTER.

Cal. very large, four-parted: the upper diviſion cleft at the end. *Cor.* permanent.

SPECIES.

1. Cyliſta villoſa. *Hairy Cyliſta.*
   Ait. hort. kew. 3. 36.
   It flowers in april and may, and was introduced in 1776, but from what country is not known. It is a ſhrub, and requires the heat of a ſtove to preſerve it.

CYMBACHNE. (*From* κυμβη, *a boat, and* αχνη, *a glume or chaff.*)

Retz. obſ. 6. 36.

Claſſ. 23. 1. Polygamia Monoecia.

Nat. order of *Gramina* or *Graſſes*.

GENERIC CHARACTER.

* *Hermaphrodite flowers.*

Cal. *Glume* two-valved, one-flowered, ſo placed that each valve is preſſed cloſe to the rachis and parallel, not one hid by the other. *Outer* valve linear, blunt, ciliate

ciliate at the back: *inner* equal in length, semiovate, acute, boat-shaped, very much compressed, striated, coloured, ciliate at the back, including the corolla.
COR. two-glumed, hyaline, smaller than the calyx.
STAM. *Filaments* three. *Anthers* black.
PIST. *Germ* minute. *Style* simple. *Stigmas* two, black-bearded.

* *Female flowers.*

CAL. one-valved, ovate, slightly bifid at the tip, ciliate at the edge, opposite to the rachis, pressed close.
COR. none.
PIST. as in the hermaphrodite, but with longer stigmas.

ESSENTIAL CHARACTER.

Inflorescence half-spiked.
HERM. *Cal.* two-glumed, one-flowered, parallel to the rachis, outer valve linear, the opposite boat-form.
FEM. *Cal.* one-glumed, ovate, opposite to the rachis.

SPECIES.

1. Cymbachne ciliata.
Retz. obf. 6. 36.

DESCRIPTION, *&c.*

This is a slender grass, a foot in height, with several culms, simple or branched, with a single leaf or leafless. Leaf short, slender, ciliate on the edge above the sheath with long separate hairs: sheath truncate, with a pale brown mouth, and ciliate. Spikes two terminating, linear, an inch and half long, a line broad, some hermaphrodite, others female. Rachis linear, membranaceous, flat behind with three longitudinal streaks, alternately and flexuosely hollowed out in front.

Native of Bengal, where it was detected by König*.

CYMBALARIA. See *Antirrhinum* and *Saxifraga*.

CYMBARIA. (*From κυμβη, cymba, a boat: the fruit being boat-shaped.*)
Lin. gen. n. 751. *Reich.* 809. *Schreb.* 1008. *Amm. Ruth.* 1. *Juff.* 119. *Gærtn.* 53.
Class. 14. 2. Didynamia Angiospermia.
Nat. order of *Personatæ—Scrophularieæ*. Juffieu.

GENERIC CHARACTER.

CAL. *Perianth* ten-toothed, erect: two opposite teeth stronger and more spreading: the rest erect, linear: permanent.
COR. one-petalled, ringent. *Tube* oblong, bellied. *Border* two-lipped: *upper lip* two-parted, reflex, obtuse; *lower lip* three-cleft, obtuse.
STAM. *Filaments* four, length of the tube. *Anthers* two-cleft, prominent.
PIST. *Germ* ovate. *Style* filiform, length of the stamens, tip incurved. *Stigma* obtuse.
PER. *Capsule* ovate, one-celled, two-valved, (subcordate, membranaceous, two-celled, *G.*) *Receptacle* quadrangular, (kidney-form, very large, *G.*)
SEEDS very many, cornered, smooth, (compressed, *G.*)
OBS. *The calyx alone easily distinguishes the genus from all others.*

ESSENTIAL CHARACTER.

Cal. ten-toothed. *Capf.* cordate, two-celled.

SPECIES.

1. Cymbaria daurica.
Lin. fpec. 861. *fyft.* 558. *Reich.* 3. 141. *mant.* 417. *Amm. ruth.* 47. *t.* 1. *f.* 2. *Gmel. fib.* 3. 198. *n.* 8. *Gærtn. fruct.* 252.

DESCRIPTION, *&c.*

The whole plant is hoary, and nearly allied to Antirrhinum. Branches opposite, barren. Flowers lateral, very few, subsessile, large. Upper lip of the corolla vaulted; lower equal; palate gibbous*. Capsule slender, brown-bay, marked with a deep groove on each side, gaping only on the edge: when it is ripe the valves become narrower than the receptacle: partition contrary to the valves. Seeds from twelve to fixteen in each cell, oblong, with an irregular membranous edge, of a bay colour*.

Native of the mountains of Dauria.

CYMINOSMA. See *Laxmannia*.
CYMINUM. See *Cuminum*.]

* Retz. * Linn. mant. * Gærtner.

CYNANCHUM. (*From κυων, a dog, and αγχω, to ſtrangle. Hence Κυναγχη, a diſorder in the throat.*)
Lin. gen. n. 304. *Reich.* 331. *Schreb.* 430. *Gærtn. t.* 117. *Juſſ.* 147.
Claſſ. 5. 2. Pentandria Digynia.—Decandria *according to ſome.*
Nat. order of *Contortæ*. *Apocineæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-toothed, erect, very ſmall, permanent, (five-parted, acute, ſpreading, *Schreb.*)
COR. one-petalled. *Tube* ſcarce any. *Border* five-parted, flat: *diviſions* linear, long, (lanceolate, *S.*) *Nectary* in the centre of the flower, length of the corolla, erect, cylindric: with a five-cleft *mouth*.
STAM. *Filaments* five, length of the *nectary*, parallel. *Anthers* touching, within the mouth of the corolla.
PIST. *Germ* oblong, two-cleft. *Style* ſcarce any. *Stigmas* two, obtuſe.
PER. *Follicles* two, oblong, acuminate, one-celled, gaping lengthwiſe.
SEEDS numerous, oblong, crowned with a down, placed in an imbricate manner.
OBS. C. viminale *departs a little from the character here given.* Mant. 392. R.

Schreber, who takes the character from C. acutum, gives it thus:

CAL. and COR. as above.
NECT. growing to the tube of the filaments, erect, one-leafed plaited in angles, ten-toothed: teeth five longer, ſharp, five alternate ſhorter, emarginate. From the bottom of the nectary ariſe five triangular, erect, thickiſh leaflets, furrowed in the middle, obtuſe, oppoſite to the longer toothlets.
STAM. *Filaments* thickiſh, conjoined into a ſhort tube. *Anthers* oblong, preſſed cloſe, two-celled, ending in an inflex membrane incumbent on the ſtigma: winged on each ſide. *Pollen* conjoined in ten oval, flat corpuſcles, concealed within the cells of the anther, fixed to it by ſhort, horizontal threads: which are faſtened by pairs to five cartilaginous twin tubercles, each fitting on the tip of the wings of the anthers at the notches of the angles of the ſtigma.
PIST. *Germs* two, ovate-oblong. *Styles* two, ſubulate. *Stigma* common to both, large, five-cornered, with emarginate angles; in the middle two conical, obtuſe, ſmall tubercles.
PER. and SEEDS as in the other.

ESSENTIAL CHARACTER.

Contorted. *Neft.* cylindric, five-toothed.

Stem twining, leaves acuminate-oblong, rolled back at the edge, flowers umbelled.

DESCRIPTIONS, &c.

These are shrubs or undershrubs, commonly twining. Leaves opposite. Flowers axillary or terminating, disposed in spikes, corymbs or umbels[a].

Nothing has given more trouble to botanists, or given rise to a greater variety of opinions among them, than the structure of the genitals in this genus and that of Asclepias. Tournefort, Desfontaines, Desfontaines, Richard, Jacquin, Rottboll, Kolreuter, Cavanilles may be consulted on this subject. The parts are so very small, and are furnished with a such compound apparatus, that it is very difficult to determine any thing about them with certainty.

They have all two germs running out into conical styles, covered with a fungose pentagon body, all of which, except the upper surface of the latter, are so covered, first with a sheath, and then with little bags hanging down and pressed close, that there does not seem to be the minutest opening to these parts. In each of the five angles of the fungose body (which Linnæus calls *corpus truncatum*, and Jacquin the stigma) is a very small ovate body, or tubercle, sharp at bottom, whence arise two filaments, which either widen into a club, or are terminated by transparent yellowish balls: these clubs or little balls are almost always taken up by the bags, which open at the top, and grow narrower towards the base. Kolreuter and Rottboll will not allow the five-cornered fungose body to be the stigma, as there is every reason however to suppose it is.

Authors disagree as to the number of anthers in the flowers of Cynanchum, and of course as to its place in the sexual system. Linnæus with his editors, and the French botanists allign only five, whilst the German botanists and Cavanilles attribute ten anthers to the flower. There are five tubercles, as we have observed, at the five corners of the fungose body, whence arise ten filaments finer than a hair, ending in a club or else a little ball: they who take the latter for anthers place these plants in the class Decandria, whilst others, who look upon the former as the anthers, place them in the class Pentandria[b]. These parts are well figured and described in the first volume of Jacquin's Miscellanea.

1. Naked Cynanchum, so called from its having stems without any leaves on them, was supposed by Linnæus to be an Euphorbia, and is thus described under that name by Miller.] It sends out a great number of slender taper stalks of a dark green colour, which are smooth, and twist about each other, or any neighbouring support, and then will rise to the height of ten or twelve feet, putting out smaller

[a] Jussieu. [b] Cavanilles hisp. p. 5.

branches at top, which alſo twine about the other ſtalks.

[Calyx five-parted. Corolla rotate, like that of Aſclepias, with a membranaceous edge ſurrounding the ſtamens and piſtils. Nectaries five, reſembling petals, erect, having a yellow perforated grain (or tubercle) with a ſmall claw on the inſide, and placed in a ring. Anthers minute, brown, placed on a head[a].

Native of the Cape of Good Hope. Cultivated in 1759, by Mr. Miller[b].] It has not flowered in England.

2. Root perennial, creeping. Stems annual, twiſting like hops round whatever plants are near them, and riſing to the height of ſix or eight feet. Leaves ending in acute points, and placed in pair, on long footſtalks. Flowers in ſmall axillary bunches, of a dirty white colour. [Jacquin ſays of a very pale fleſh-colour, with lanceolate, bluntiſh ſegments, ſpreading open very much, and flat. Leaflets of the calyx lanceolate, ſmall, greeniſh. From the tube of the petal aſcends the nectary, which is bell-ſhaped, of the ſame colour with, and ſhorter than the corolla, divided above two thirds of its length into five lanceolate, acute, erect ſegments, ſo far removed from each other as to admit five other very ſmall rounded ſegments, ſometimes quite entire, ſometimes lacerated, or bifid. Sheath conical and narrow at the baſe; thence widening, and divided into five two-celled oblong bractes, ending in as many rounded ſcales, and embracing the mouths of the ſtigma. Between theſe, to the margin of the ſtigma are fixed the ſtaminiferous tubercles, putting forth from their baſe on each ſide a ſingle very fine horizontal filament. Anthers pale, roundiſh-ovate, flat, fixed by their middle part, and containing a pulpy pollen. Germs two, ovate-oblong, ending in two ſhort ſtyles, which are crowned by a diſcoid pentagon ſtigma, common to both[c].

This deſcription of the fructification may be compared with the generic character given above from Schreber. According to Gærtner, the calyx is five-toothed, the corolla five-cleft, no nectaries, ten pendulous ſtamens, concealed within the involucre of the germs, which are two, involucred by five ſcales united into a cylinder. Follicles diverging horizontally as they approach to maturity, columnar, ſmooth: receptacle linear, membranaceous, free. Seeds ſeveral, imbricate downwards, ovate-oblong, flatted a little, ſurrounded by a narrow, membranaceous rim, with a lateral umbilicus in it, of a reddiſh ferruginous colour, and crinite; the hairs ſimple, ſilky-white, five times as long as the ſeeds.

Native of Spain and Sicily. Cultivated in 1596 by Gerarde[d].]

It flowers in June and July, but does not produce ſeeds in England: occaſioned probably by the roots creeping ſo far under ground; for moſt plants which propagate themſelves ſo much by their roots become barren, eſpecially if their roots have full liberty to extend.

[3. This is a milky plant, with twining, round, ſmooth ſtems. Leaves oblong-cordate, acuminate, quite entire, very ſoft, with a ſcarcely conſpicuous nap underneath, ſmoothiſh on the upper ſurface, but bearded at the origin of the petiole with abrupt rigid ferruginous, very ſhort cilias. Common pedunckes ſmooth, lateral, ſolitary, ſuſtaining about five flowers, on pedicels elongated beyond the common one. Flowers void of ſcent, very flat, half an inch in diameter; corollas veined and ſcruginoſe; calyxes greeniſh white.

The parts of fructification are thus deſcribed. *Perianth* five-leaved; leaflets lanceolate, flat, acuminate, ſpreading very much, ſlightly coloured, generally exceeding the corolla in length. *Corolla*, tube ſpreading, very ſhort: border five-cleft, diviſions ovate-roundiſh, ſpreading very much, and flat. *Nectaries* five, connected at their ſides ſo as to form one body of the ſame form and ſize as the tube of the corolla; in the centre of the flower produced from their baſe riſing into five blunt, upright little bodies, twice as long as the tube of the corolla, furniſhed at the top with cowled two-celled little membranes. *Filaments* ten, capillary, ſhort, in pairs from the ſame point between the cowls of the nectary. *Anthers* obovate, obtuſe, columnar, upright, concealed by the cowls. *Germs* two, ovate, convex on one ſide, flat on the other, the ſame length with the tube of the corolla, in the centre of the nectary. *Styles* two, ſhort, upright. *Stigma* ſingle, ſimple, very large, quinquangular, cloven in the centre, funnel-form.

Native of Carthagena in New Spain; flowering in July and auguſt.

4. Stems herbaceous, twining, ſmooth, ſcandent, full of a white milky juice. Leaves quite entire, ſhining, ſlightly waved, bright green on the upper ſurface, æruginoſe on the back, petioled. Racemes lateral, three inches long, ſolitary; but by the ſide of the principal a ſmaller branch comes out, which is alſo loaded with flowers; they are ſmall, white, and void of ſcent.—*Calyx* five-leaved, leaflets lanceolate, concave, acute, patulous. *Corolla*, tube bell-ſhaped, very ſhort: border five-cleft, diviſions lanceolate, flat, ſpreading very much, revolute and emarginate at the end, a little longer than the calyx. *Nectaries* five, erect, the length of the calyx, ovate, flat, three-jagged and acuminate at the end: in the centre of the flower from its baſe produced, finally riſing into five oblong ſhort blunt little bodies, which end in membranes that are cowled, and rendered two-celled by a middle partition. *Filaments* ten, capillary, very ſhort, in pairs from the ſame point between the cowls of the nectary. *Anthers* oval, columnar, upright, concealed in the cells of the cowls. *Germs* two, very ſmall, in the centre of the nectary. *Style* ſingle, filiform, upright, almoſt the length of the nectary. *Stigma* very large, flat on both ſides, with five ſharp angles.

Native alſo of Carthagena; flowering in october and november.

5. This alſo is a milky plant, with twining, round, hirſute ſtems. Leaves acuminate, quite entire, petioled, from two to four inches long. Pedunckes one-flowered and ſhortiſh, ſpringing aggregately from a tubercle among the leaves. Flowers without ſcent, with a green calyx, and a dark purple corolla. *Calyx* five-parted: with lanceolate, acute, ſmall leaflets, ſpreading very much. Tube of the *corolla* very ſhort, ſpreading; ſegments of the border ovate, acute, flat, large, hirſute within, ſpreading very much. *Nectary* bell-ſhaped, conſiſting of five obcordate, three-toothed, ſpreading leaflets, connected at the ſides into one body, of the ſame colour with the corolla, and of the ſame length with the calyx; riſing into five little bodies in the centre of the flower, furniſhed with five membranaceous, cowled, two-celled ſcales. *Filaments* ten, capillary, ſhort, in pairs from the ſame point between the ſcales of the nectary. *Anthers* obovate, columnar, upright, concealed in the cowls. *Germs* two, ovate, convex on one ſide, flat on the other, in the centre of the nectary. *Style* cloven at the baſe, at the height of the ſcales ſpread out into a body flat on both ſides, wide, and thirply five-cornered: from the centre of this it again emerges ſingle, filiform, erect, the length of the corolla. *Stigma* bifid: the diviſions obtuſe, ſpreading.

Native of Terra Bomba, on the coaſt; flowering in november[e].]

6. Root perennial. Stems ſlender, hairy, twining, and if ſupported riſing ſix or ſeven feet high: the lower part is covered with a thick fungous bark, ſomewhat like cork, and full of fiſſures. At each joint is a pair of leaves on long hairy footſtalks. The flowers are in ſmall axillary bunches; they are ſtar-ſhaped, and green when they firſt appear, but afterwards change to a duſky purple colour. They

[a] Linn. mant. from Baſſ.
[b] Miſcell. 1. 16.
[c] Hort. kew.
[d] Hort. kew.
[e] Jacq. amer.

appear

appear in july and auguſt, but are not ſucceeded by ſeeds in England. Native of Carolina, whence the ſeeds were brought to England. [Cultivated in 1732, by James Sherard, M. D. [1].]

7. This riſes with a twining ſtem to the height of twenty feet or more, if ſupported; the lower part is cork-barked and full of fiſſures like the preceding. Leaves like that on long footſtalks, but ſmooth. Flowers of a yelloviſh green colour, not ſucceeded by pods in England. It grows naturally in Jamaica, whence the ſeeds were ſent to Mr. Miller by Dr. Houſtoun [before 1733 [2]].

8. Stems filiform, green, ſmooth, ſwelling at the joints, very long, climbing. Leaves acute, glaucous, about the ſame length with the petioles. Flowers on ſoliitary, peduncled racemes between two petioles, the pedunclès thickening towards the top. Calyx ſmall, five-cleft. Corolla deeply five-parted; ſegments linear, white above, pale roſe-coloured beneath: in the centre is a whitiſh pitcher-ſhaped body, ten-cleft at the top, with five broad ſhorter ſegments, and five ſharp longer ones, ornamented internally with as many ſharp appendages, which are raiſed upwards: in the middle of this body is placed a ſheath, obſcurely five-cornered, with five pendulous two-celled appreſſed little bags, ending at top in as many orbicular ſcales, converging towards the top of the ſheath. Stamens ten, very ſhort, capillary, inſerted by pairs into an obovate root: anthers ten, globular, concealed within ten receſſes of the bag: the roots of the ſtamens appearing between the ſcales. Germs two, approximating, ending in conical ſtyles: the ſtigma is common to both, of a pentagon figure, forming the roof or top of the theca or ſheath, crowned by two toothlets, approximating at the baſe, afterwards divaricating [3].]

The leaves are broader and rounder at their baſe than in the ſecond ſort. The roots are very thick, running deep into the ground, and extending themſelves far on every ſide. Both theſe plants abound with a milky juice like the Spurge, which iſſues out wherever they are broken; and this, when concreted, has been frequently ſold for Scammony.

[Native of the South of Europe. Cultivated in 1597, by Gerarde [4].]

9. From an annual root divided into whitiſh fibres a foot and half long, and not ſo thick as a quill, ariſes a twining ſtem, very much branched, twelve feet high, round, villoſe, with longer hairs thinly interſperſed, rough, glaucous, when far advanced ſlightly tinged with purple. The branches are the ſame. Leaves quite entire, almoſt ſmooth on both ſides, on a long round villoſe petiole. The common pedunclès come out between the oppoſite petioles, commonly ſingle, but ſometimes on each oppoſite ſide, from half a foot to a foot in length, round, rugged, villoſe, ſpreading, leafleſs. Pedicels an inch and half long come out aggregately at intervals from the former. Flowers pendulous, ſweet-ſmelling, beginning to open about ſix o'clock in the evening, and cloſed by morning; they are of a greeniſh pale colour. The plant is elegant, and abounds with white milk. The character of the fructification is as follows. *Perianth* five-cleft, ſmall, ſomewhat villoſe, permanent: leaflets lanceolate, acute, erect. *Corolla* wheel-ſhaped: tube ſubquinquangular, longer than the calyx: diviſions of the five-cleft border lanceolate, acute, three times the length of the tube, flat, except that the ſides are rolled back, ſpreading very much, very cloſely and ſoftly ciliate, with hairs about the edges. *Nectary*, the ſheath from the tube of the corolla, to which it grows, is elevated into a pentagon five-grooved white cone ſhorter than the petal: this cone conſiſts of five erect obtuſe bractes, three-lobed at the tip, the middle lobe longer, and lying on the vertex of the ſtigma, on the inſide having two little bags for the lodgement of the anthers: to each bracte at the baſe of the double bag on the back is faſtened a lanceolate convex appendix, bent in both ways, acute, erecting itſelf from the middle of the ſheath beyond the ſtigma. *Filaments* ten, ſhort, from each brown point between the bractes of the ſheath conſpicuous on the ſtigma in pairs. *Anthers* obovate, compreſſed, pendulous, yellow. *Germs* two. *Styles* two, awl-ſhaped. *Stigma* capitate, globular, with an obtuſely five-cornered rim about the edge. *Follicles* lanceolate-acuminate, muricate, turgid, glaucous, coriaceous, diverging or reflex. *Seeds* very many, flat, with a ſilky down, and fixed to the receptacle [1].

Jacquin has retained the name *extenſum* originally given it by the celebrated Solander from the elongated pedunclès. Retzius, who had it from König, calls it *cordifolium*; and ſays that the leaves are roundiſh-cordate, ſometimes a little angular, and ſmooth on both ſides; that the flowers are in cymes, on ſlender pedicels proceeding from a tubercle, with a ſmall ſhort bracte under each.

Native of the Eaſt-Indies. Introduced in 1777, by Patrick Ruſſell, M. D. It flowers in july and auguſt [2].

10. This is a milky plant, entirely ſmooth, with twining round ſtems. Leaves quite entire, fat to the touch, on very ſhort petioles, four inches long. A ſolitary, cloſe, ſmall umbel is placed on a round, thickiſh, lateral pedunclè, uſually longer than the petiole. Flowers ſmall, without ſcent, firm; calyxes aſh-coloured, corollas nearly of the ſame colour on the outſide, and dirty purple within. Perianth five-leaved: leaflets ovate, concave, ſpreading. Corolla, tube globular-depreſſed, a little longer than the perianth: border five-cleft; ſegments flat, very blunt, ſpreading much, half the length of the tube: throat ſpreading very wide. In all other parts like *C. altiſſimum*.

Native of Carthagena in New Spain; flowering in july [3].

11. Stem lofty, ſcarcely pubeſcent, even at top, by no means cork-barked. Leaves petioled, mucronate, even; the younger ones ovate, the more advanced emarginate. Pedunclès axillary, ſhorter than the leaves, toothletted, ſimple: pedicels alternate, capillary, longer than the pedunclè. Calyx very ſhort. Native of the Cape of Good Hope. Obſerved by König and Sparrmann [4].

12. This alſo is a native of the Cape: and was firſt obſerved there by Thunberg [5].

13. Stem filiform, herbaceous, with alternate branches. Leaves oppoſite, petioled, even, the ſize of Chickweed, mucronate. Umbels lateral, irregular, ſhorter than the leaves, ſeſſile. Flowers the ſize of Galium. Two ſubulate follicles, the length of a finger. Found in New Granada, by Mutis [6].]

14. This is a perennial plant, which riſes with ſlender upright ſtalks about three feet high. Leaves broad, ſmooth, ending in points. Flowers axillary, in ſmall bunches, on branching pedunclès; they are ſmall and white, greatly reſembling thoſe of the common white Aſclepias.

[The fructification is thus deſcribed by Jacquin. *Perianth* green, ſmall, ciliate, five-cleft: ſegments lanceolate, acute, erect. *Corolla* white, divided almoſt to the baſe into five oblong, obtuſe, flat ſegments, all together forming at bottom an almoſt bell-ſhaped corolla, but ſpreading very much at top, and ſlightly bent with the apparent courſe of the ſun. The theath is placed immediately on the pedicel of the flower; below it is round, green, and has two grooves; above the germ from the back below the bractes it puts forth five petal-ſhaped, white, ſublinear, obtuſe, upright, ſmall leaflets; but here the ſheath itſelf becomes oblong, concave bractes, ending in a roundiſh ſcale, yelloviſh, applied to the ſtigma, and half its length: theſe bractes have not any two-celled bags, but inſtead of them two roundiſh yellow ſmall plates,

[1] Hort. kew. [2] Ibid. [3] Cavanilles. [4] Hort. kew.
[1] Jacquin. [2] Hort. kew. [3] Jacquin. [4] Linn. ſuppl. [5] Ibid. [6] Ibid.

ſituated

ſituated above the baſe in a parallel poſition, and extended forward. *Germs* two, obtuſe, pale: ſtyle very ſhort, thick, ſingle and undivided, common to both germs: ſtigma very large, elongate-conical, thick, erect, pale yellow, bifid and obtuſe at the end, very long. At the ſides of the ſtigma between the bractes about the middle are linear brown tubercles, from each of which ariſe two yellow obovate flat anthers, hanging forward between adjoining plates of neighbouring bractes and their edges, almoſt without filaments [a].

Native of Syria. Cultivated in 1640. It flowers in july and auguſt [b].

15. Found at the Cape, by Thunberg [c]. There is a ſpecies deſcribed under this name by Jacquin, entirely diſtinct from this [d]. See n. 26.

16. Native of South America, and the Weſt-Indies. Cultivated before 1741, by Robert James Lord Petre. It flowers in july [e].

17. Stem woody, covered with a thick whitiſh bark, the branches twining, ſtriated, ſmooth. Leaves far from each other, petioled, ſmooth, the upper ones lanceolate. Flowers ſmall, hairy on the outſide, unequally pedicelled in peduncled axillary umbels.

Native of the Eaſt-Indies, and obſerved there by König [f].

18. Stem ſhrubby, twining, twenty feet high or more, very ſlender, and armed with ſmall ſtinging hairs. Leaves broad heart-ſhaped, ending in acute points by pairs at each joint, which are far diſtant, on ſlender foot-ſtalks: they are covered with rough hairs on their under ſide. The flowers are produced in ſmall cluſters, ſitting cloſe to the ſtalks: they are pretty large, yellow and ſtar-ſhaped, ſpreading open to the bottom. Follicles long, ſwelling. Seeds flat, crowned with long down. Native of La Vera Cruz in New Spain, whence the ſeeds were ſent from Dr. Houſtoun to Mr. Miller.

[19. Stem twining, ſhaggy, with reverſed hairs, as are alſo the petioles. Leaves two or three inches long, acuminate, having hairs thinly ſcattered over the upper ſurface, paler underneath, with numerous raiſed dots, viſible only with a magnifier, with a ſinus open, not cloſed as in C. criſpiflorum. Peduncles axillary, ſhorter than the petiole, ſmoothiſh. Pedicels ſubumbelled, four or five, unequal, filiform, hirſute, often twice as long as the general peduncle, but ſhorter than the leaves. Segments of the calyx ovate, thinly haired. Corolla before it unfolds ovate, acuminate-beaked: petals thrice the length of the calyx, linear-lanceolate, with a few hairs on the outſide. Found on the iſland of Trinidad by Rohr. The proper place of this is between the third and fourth ſpecies [g].

20. Native of the Weſt-Indies. Its place is between the twelfth and thirteenth ſpecies [h].

21. Stems a foot high, round, filiform, branched, knotted, tomentoſe, ſubherbaceous. Leaves in pairs at each knot, nearly equal to the petioles, quite entire, ſoft, glaucous underneath, having an unpleaſant ſmell. Flowers in ſolitary umbels: common peduncle half an inch long, between the two petioles: raya four, one-flowered, ſurrounded at the baſe by three little bractes. Calyx ſmall, divided half way into five ovate villoſe parts. Corolla deep green, deeply parted into five ſpreading ſegments, with a revolute border: in the centre is a whitiſh pitcher-ſhaped body, ſurrounding the genitals, five-parted, with the ſegments deeply two-horned; from the centre of the horns ariſe two plates, one of which is arched towards the genitals, the other is very ſmall, oppoſite to the former, and verges outwards. Genitals concealed within a ſheath, the bottom of which is occupied by two germs, which are partly united, and end in ſtyles, whoſe common ſtigma is large, five-cornered and fungoſe, ſurrounded by five little ſcales: in the corners of the ſtigma are five very ſmall brown bodies, which are the roots or baſes of the anthers; becauſe from each of theſe a pair of yellow appendages covered with little ſcales proceed, which are the anthers, and are therefore ten in number.

Native of Mexico. It flowered in the Paris garden in 1780; and the year following in the royal garden at Madrid, in the month of auguſt [i].

22. Stem very long, round, branched, thickened, and having a rufous nap at the joints. Leaves having one branching nerve; they are longer than the petiole, which is often twiſted at the baſe, and there is thicker and ſomewhat villoſe. Flowers in ſhort racemes: common peduncle thick, ſolitary, between the two petioles: pedicels in alternate pairs, an inch long. Calyx deeply parted into five acute ſegments. Corolla before it expands rolled up in a ſpiral, but afterwards ſpreading very much, deep green on both ſides, and ſomewhat coriaceous, divided into five lanceolate very ſharp ſegments near an inch in length. At the bottom of this is a yellow body the ſize of a pea, which has five hollows at the baſe, with as many claws arched inwards; from the centre ariſes a very ſhort priſm, terminated by a green pentagon; the ſides of this pentagon have each an ovate concave yellow appendicle, and at the angles are the red roots or baſes of the anthers. Filaments ten, thinner than the fineſt hair, fixed to theſe baſes by pairs, diverging, and gradually augmenting like a club: theſe ten club-ſhaped bodies are the anthers, they are tranſparent, yellow, and concealed between the ſides of the pentagon and the appendicles almoſt in a horizontal ſituation. Germs two, approximating, ending in conical ſtyles: ſtigma common, five-cornered, fungoſe, large.

Native of South America. It flowered at Madrid from ſeptember to the end of the year, about 1788 or 1789 [k].

23. Stem very long, round, ſhining, and very ſmooth, except at bottom, where it has a bark like cork. Leaves waved, ſmooth, on long petioles. Flowers yellow, very ſweet-ſcented, in large, hemiſpherical, axillary, reclining cymes. Calyx five-leaved, inferior: leaflets ovate-lanceolate, waved, almoſt erect, permanent. Corolla ſalver-ſhaped, with a thick ſhort tube, inflated at the baſe, and a wide five-parted border, with oblong ſegments, ſomewhat reflex: nectary cylindric, thick, erect, five-cleft, the ſegments converging. Filaments five, membranaceous, adhering externally to the nectary, with ten glands at the baſe; anthers two-celled, compreſſed, acute, lying on the ſtigma. Germ ovate, bifid. Stigma ſeſſile, ovate, emarginate, ſingle.

Native of Siam and Cochinchina. Cultivated there and in China. In fragrance it does not yield to the Arabian Jaſmin (Nyctanthes or Jaſminum Sambac,) and though very common, it is no leſs uſed than that by women of faſhion in thoſe countries to adorn their hair [l].

24. This is a milky ſhrubby plant, climbing trees to the height of fifty feet. Stems round, when old woody, ſmooth, aſh-coloured, leafleſs, when young green, tomentoſe, leafy. Leaves acuminate, quite entire, thickiſh, with a very ſoft but ſcarcely viſible nap on both ſides, petioled, at firſt two inches, but afterwards half a foot in length. Umbels lateral, ſolitary, cloſe, hemiſpheric; common peduncle very thick, round, tomentoſe, ſcarcely the length of the petioles; involucre many-leaved, unequal. Theſe come out with the leaves, and in the leafleſs branches from the joints. Flowers thick, firm, without ſcent; calyxes greeniſh aſh-colour; corollas dirty purple. The ſcales of the nectary, in this and a few others, may be ſaid to have three cells, the partition being double, but ſince theſe folds converge, and the anthers are placed on the outſide, the middle cell is of no conſequence. One of the follicles only ripens, the other proving abortive.

[d] Linn. ſyſt. [e] Hort. kew. [f] Retz.
[g] Vahl [h] Swartz. [i] Cavanilles. [k] Ibid.
[l] Loureiro.

25. Stems round, hairy, climbing to the height of fifteen feet. Leaves obverſely ſubovate, cordate at the baſe, quite entire, thickiſh, with hairy veins and nerves, half a foot long, on ſhort and hairy petioles. Umbels lateral, ſolitary, at moſt ſeven-flowered; common peduncle hairy, thick, round, the length of the petiole; involucre many-leaved, unequal. Flowers without ſmell or beauty; calyxes pale greeniſh; petals pale without, within ſuliginous, with numerous ſilvery hairs. One or two of the flowers are abortive before they open, leaving a ſcar. The unuſual elongation of the tube gives the flower a very different appearance from the others.

26. Stems round, filiform, ſhining, branched, very numerous. Leaves quite entire, petioled, ſcarcely an inch and half in length. Umbels ſmall, erect, lateral, alternate: common peduncle filiform, twice the length of the petioles. Flowers without ſcent, ſmall, the petals and nectary ſnow-white. Both follicles commonly ripen.

27. Stems round, ſmooth, numerous. Leaves lanceolate-oblong, acuminate, quite entire, veined, ſhining, on very ſhort petioles, from two to three inches in length. Umbels lateral, ſolitary. Flowers without ſcent, with the corollas and nectaries ſnow-white.

Theſe are all climbing milky plants, and natives of Carthagena in New Spain *.

On account of the obſcurity in the fructification, I have been the more particular in giving characters and deſcriptions at length, particularly from the celebrated Jacquin. They will not appear very intelligible without the plants themſelves, or at leaſt good magnified figures, ſuch as may be found in Jacquin's miſcellanea. But with theſe they will greatly aſſiſt the botanical ſtudent in developing theſe myſteries, and may lead him to form a more ſatisfactory generic character than has been hitherto given.

PROPAGATION AND CULTURE.

Theſe plants are chiefly inhabitants of hot climates: the greater part (3 to 5, 7, 10, 13, 16, 18 to 22, and 24 to 27) of South America and the Weſt-Indies. Two are from the Eaſt-Indies (9 and 17), and one (23) from Siam and Cochinchina.]

They are all tender, and will not thrive in this country unleſs they are placed in a bark ſtove. As they abound with a milky juice, they muſt have little water in winter. They may be propagated by laying down the young ſhoots, which in three or four months will put out roots, and may then be tranſplanted into pots filled with light ſandy earth, and plunged into the tan-bed, where the plants ſhould continue all the year.

[They may alſo be increaſed by parting the roots, or by cuttings. Such as produce good ſeeds in Europe, which many of them do not, may be propagated that way.

Four ſpecies (1, 11, 12, 15.) come from the Cape, and muſt be preſerved in the dry ſtove. They may be increaſed by layers, cuttings, &c.]

Two, (2, 8) being natives of the South of Europe, are hardy, and propagate too faſt by their creeping roots, which are not eaſily extirpated, when they have got poſſeſſion of the ground. The roots may be tranſplanted any time after the ſtems decay, till they begin to ſhoot in the ſpring.

6. The ſixth ſort from Carolina will live in the open air in England, if it be planted in a dry ſoil and warm ſituation. It may be increaſed by laying down the young ſhoots about midſummer, which, if they are now and then refreſhed with water, will put out roots, and may be tranſplanted in the autumn, where they are deſigned to remain. The roots ſhould be covered in winter with ſome rotten tan to keep out the froſt.

14. The fourteenth ſort from Syria, requires a warm ſituation, to live abroad in England. It is propagated by parting the roots in the ſpring, before they ſhoot.

DESCRIPTIONS, *&c.*

1. The Artichoke in its wild ſtate is ſaid to attain the height of a man. The leaves are much more tomentoſe than in the garden plant, and every ſmall diviſion of them is armed with a ſtrong yellowiſh ſpine. The heads are much ſmaller, and have much larger ſtronger ſpines at the ends of the ſcales.

The cultivated Artichoke ſeldom riſes above four feet in height, with a ſtout, furrowed, leafy ſtem, ſlightly tomentoſe, ſometimes a little branched at top. The root is large, thick, and perennial, crowned by a conſiderable cluſter of pinnatifid leaves, from two to four feet in length, pointing upright, the whole covered with an aſh-coloured down, eſpecially underneath: the midrib has a deep ſingle channel above, and ſeveral deep furrows underneath, with ſtrong ridges between them: at bottom there are uſually ſeveral ſeparate leaflets or rudiments of leaves, which increaſe in ſize till the main leaf begins, and are connected by a wing running down each ſide of the midrib; this wing increaſing, then unites the remainder into one pinnatifid leaf, very deeply cut, and each cleft has a few large ſerratures or jags, ending in a ſhort prickle, which is ſometimes ſcarcely perceptible. The leaves on the ſtem are ſimple, only ſerrate or jagged, like a ſingle cleft of the other: they end obtuſely, and are frequently retuſe; ſometimes they have ſcarcely any ſerratures; immediately below the heads are ſome looſe ſcales, partaking of the nature of the upper leaves and calycine ſcales. The heads are ſubglobular, either green or dark purple, the former commonly tinged at bottom with purple; compoſed of numerous, large, ovate ſcales, which at bottom are very fleſhy, and at top are obtuſe and emarginate, or cloven. If theſe heads be ſuffered to ſtand, the calyx will open, and a great number of jagged purple florets will appear. Theſe are placed on a large fleſhy receptacle, commonly called the bottom; and together with the briſtles interpoſed between the florets, and the down of the ſeed, form what is vulgarly called the choke, in the immature ſtate of the head, in which ſtate only the calycine leaves are ſucked, and the receptacle or bottom eaten, deprived of the maſs of florets, &c. or choke.

The Artichoke is a native of the South of Europe, as Italy, Sicily, the South of France, &c. In ſome parts it is eaten raw in its wild ſtate, by the common people, and ſurely muſt be a moſt wretched food. It is ſaid to dye a good yellow: and the flowers are uſed inſtead of rennet to turn milk for cheeſe. The whole plant has a peculiar ſmell, and a ſtrong bitter taſte. It was formerly in great requeſt for qualities which it is not now allowed to poſſeſs. It is reputed to be aperitive, ſtomachic, and ſomewhat heating.

β. γ. Mr. Miller makes two ſpecies of the Common Artichoke. 1. C. Scolymus, the Green or French. 2. C. hortenſis, the Globe Artichoke.]

The firſt of theſe, being the ſort moſt commonly cultivated in France, is generally known here by the title of French Artichoke, and is the only ſort in Guernſey and Jerſey. The leaves are terminated by ſhort ſpines, the head is oval, and the ſcales do not turn inwards at the top like thoſe of the Globe Artichoke; the heads are alſo of a green colour, the bottoms are not near ſo thick of fleſh, and they have a perfumed taſte, which to many perſons is very diſagreeable; ſo that it is ſeldom cultivated in the gardens near London, where the Globe or Red Artichoke is the only ſort in eſteem. The leaves of this are not prickly, the head is globular, a little compreſſed at the top, the ſcales lie cloſe over each other, and their ends turn inwards, ſo as cloſely to cover the middle.

[The leaves of the latter are of a bluer caſt, with more and deeper jags on the clefts; they have ſmall inert prickles, like the other, but not ſo perceptible: the leaves of the former are larger, much wider, and of a paler colour, inclining to yellow on the upper ſurface. The great openneſs of the ſcales in the head of the Green Artichoke is a leading character; it alſo rather draws up to a point in the middle, whereas the Globe Artichoke is quite flat at top: the colour is a reddiſh brown, or rather a duſky purple, with a tinge of green.

We learn from Turner that the Artichoke was certainly cultivated in England in 1551[a]. We probably had it much ſooner.

Gerarde (a. 1597.) ſays that our great Artichock, which was firſt brought out of Italy, is become, by reaſon of the great moiſture which our country is ſubject unto, greater, and better than thoſe of Italy, inſomuch that divers Italians have ſent for ſome plants of our Artichockes, deeming them to be of another kind; nevertheleſs in Italy they are ſmall and dry, as they were before. And Parkinſon (parad. printed in 1629) affirms that our Engliſh red Artichoke is the moſt delicate meat of any other, and has been ſent into Italy, France, and the Low Countries; but that they degenerated there in two years: ſo that it ſeemeth that our ſoil and climate hath the preheminence to nouriſh up this plant to its higheſt excellency.—He alſo adds, that the French Artichoke was brought over, after a great froſt had well nigh conſumed our beſt kinds, and are now almoſt clean caſt out again, none being willing to have it take up the room of better. It is remarkable that this is the ſame account with that which is given by Mr. Miller, after the great froſt of 1739-40, above a century afterwards.

The Artichoke has the ſame name, with very little variation, in the European languages. In German it is *Artiſchoke*, corruptly *Erdſchocke*[b]; in Dutch *Artiſjok* or *Artichok*; in Daniſh *Artieſtok*; in Swediſh *Aertſhocka*; in French *Artichaut*; in Italian *Carciofo*; in Spaniſh and Portugueſe *Alcachofa*; in Poliſh *Karcioſ*; in Ruſſian *Artitſchok*.

2. Native of the iſland of Porto Santo, near Madeira. Mr. Francis Maſſon. Introduced in 1778[c].

3. John Bauhin affirms that the Cardoon is a hybrid plant or mule from the ſeed of the Common Artichoke. The corollets and piſtils of this are of a deep blue colour, but the ſtamens are gray. Native of the iſland of Candia[d]. Cultivated in 1683, by Mr. James Sutherland[e]. Parkinſon ſays[f], he was aſſured by John Tradeſcante, that he ſaw three acres of land about Bruſſels planted with this kind, which the owner whited like Endive, and then ſold them in the winter; but that we cannot yet find the true manner of dreſſing them, that our country may take delight therein. It is evident, therefore, that Cardoons were not cultivated here in 1629.

In ſome parts of Spain they ſubſtitute the down of this plant for rennet, in making cheeſe. A ſtrong infuſion is made over night; and the next morning, when the milk is warm from the cow, they put nearly half a pint of the infuſion to about fourteen gallons of milk[g]. This plant has the ſame name with ſlight variations in all the languages of Europe, as Kardonen, Kardon, Cardone and Cardo.]

4. This is very like the preceding, but the ſtems of the leaves are much ſmaller, and do not grow more than half ſo high. The heads have ſome reſemblance to thoſe of the French Artichoke, but have no fleſhy ſubſtance in their bottoms. [The ſtem is ſcarcely the length of the leaves. The calycine ſcales are ovate-oblong and ſpreading. The ſeeds in this ſmaller ſpecies are much larger than in the others, and ſingular[h].

[a] Hort. kew. [b] Ibid. [c] Linn. ſpec.
[d] Hort. kew. [e] Parad. 520. [f] Towns. Spain, vol. 1. 297.
[g] Linn. ſpec.

According to Juſſieu, it is of a diſtinct genus; the flower being radical, and the calycine ſcales unarmed, but ciliate-palmate at the tip as in Jacea.

Native of Spain and Barbary. Cultivated (before 1683) in the botanic garden at Oxford, from ſeed ſent by Alexander Baalam from Tangier. It flouriſhed there many years, but periſhed at length in the winter of 1683, never to be forgotten for its ſeverity [h].

5. Native of Barbary.

6. This is a low ſmooth plant, with a ſimple ſtriated ſtem. Leaves petioled, broad lanceolate, remotely toothletted, with minute ſpines, mucronate, an inch and half long. Flower terminating, peduncled, ſolitary, only half the ſize of the Common Artichoke. Scales of the calyx lanceolate-acuminate, the lower ones ending in a ſomewhat pungent ſpine. Corollas blue. Found by Barnadas in the mountains near Toledo in New Caſtille [i].]

PROPAGATION AND CULTURE.

1. The manner of propagating the Common Artichoke is from ſlips or ſuckers taken from the old roots in february or march; or rather ſome time in march, or the beginning of april; which, if planted in a good ſoil, will produce large fair heads the autumn following.

Method of Planting.

When you have a mind to make a new plantation, after having digged and buried ſome very rotten dung in the ground you have allotted for that purpoſe, make choice of ſuch of your plants as were taken from your old ſtocks, which are clear, ſound, and not woody, having ſome fibres to their bottom; then with your knife cut off that knobbed woody part which joined them to the ſtock; and if that cuts criſp and tender, it is a ſign of its goodneſs; but if tough and ſtringy, throw it away as good for nothing; then cut off the large outſide leaves pretty low, that the middle or heart leaves may be above them. Your plants being thus prepared, if the weather is very dry, or the plants have been any time taken from the ſtocks, it will be convenient to ſet them upright in a tub of water for three or four hours before they are planted, which will greatly refreſh them; you muſt then proceed to planting, which muſt be done by ranging a line acroſs the ground, in order to their being placed exactly in a row; and, with a meaſure-ſtick, plant them at two feet diſtance from each other in the rows, and if deſigned for a full crop, five feet diſtance row from row; your plants muſt be ſet about four inches deep, and the earth cloſed very faſt to their roots, obſerving, if the ſeaſon proves dry, to keep them watered two or three times a week, until they are growing, after which they ſeldom require any.

You may ſow a thin crop of Spinach upon the ground before you plant your plants, obſerving to clear it from about them after it is come up.

Theſe plants, in a kindly ſeaſon, or a moiſt ſoil, will produce the largeſt and beſt Artichokes ſome time in auguſt and ſeptember, after all thoſe from the old ſtocks are paſt; ſo that if you intend to continue your Artichokes through the whole ſeaſon, you muſt make a new plantation every year, otherwiſe you cannot poſſibly have fruit longer than two or three months.

If any of the plants which are planted in the ſpring ſhould not fruit in autumn, you may, at the ſeaſon of earthing up your roots, tie up the leaves with a ſmall Willow twig, &c. and lay the earth up cloſe to it, ſo that the top of the plant may be above ground; and when the froſt comes on, if you will cover the top with a little ſtraw, or Peaſe-haulm, to prevent their being killed by froſt, theſe plants will produce fruit in winter, or early in the ſpring.

But in thoſe plantations where you intend to plant other things between your Artichokes, you muſt allow nine or ten feet between the rows, as is often practiſed by the kitchen-gardeners near London, who ſow the ground between with Radiſhes or Spinach, and plant two rows of Cauliflowers, at four feet diſtance row from row, and two feet and a half aſunder in the rows, ſo that there are always five feet allowed for the Artichokes to grow; and in may, when the Radiſhes or Spinach are taken off, they ſow a row of Cucumbers for pickling, exactly between the two rows of Cauliflowers, at three feet diſtance from each other; and between the rows of Cauliflowers and the Artichokes, plant a row of Cabbages or Savoys for winter uſe, which, when the Cauliflowers are drawn off, and the Artichokes gathered, will have full liberty to grow, and by this means the ground is fully employed through the whole ſeaſon. This has long been the practice of the kitchen-gardeners near London, who pay large rents for their land, ſo are obliged to get as many crops in a year from it as poſſible.

In thoſe which are planted at five feet diſtance row from row, you may plant in every other row a line of Cabbages or Savoys for winter uſe, which will be gone by the time of landing them up; in doing of which you muſt lay the whole five feet of earth into one ridge, except the ground be extreme ſtiff, or the plants young, in both which caſes you may lay only three feet and a half of the ground in the ridge over the roots, and the remainder may be laid in a ſmall ridge between; the ſame compaſs of ground muſt alſo be allowed where they are planted at a wider diſtance.

And if in the ſpring you find your ſtocks ſhoot very weak, which may have been occaſioned either by hard froſt, or too much wet, you muſt then uncover them, and with your ſpade looſen and break the earth about them, raiſing a ſmall hill about each ſtock, levelling the reſt between the rows, which will greatly help them, and in three weeks, or a month's time after, they are commonly fit to ſlip.

Thoſe Artichokes which are planted in a moiſt rich ſoil, will always produce the largeſt and beſt fruit; ſo that where ſuch a ſoil can be obtained, it will be proper to make a freſh plantation every ſpring, to ſucceed the old ſtocks, and ſupply the table in autumn. But the roots will not live through the winter in a moiſt ſoil, ſo that your ſtocks which you intend ſhould remain to ſupply the table early, and to furniſh plants, ſhould be in a drier ſoil. You ſhould always obſerve to plant theſe in an open ſituation, and not under the drip of trees, where they will draw up very tall, and produce ſmall inſignificant fruit.

Winter dreſſing and landing.

Since we have experienced that, in very ſevere froſts theſe roots are ſometimes deſtroyed, therefore it is proper to give ſome directions to prevent it; though this rarely happens in dry ground, in which we have but few inſtances of their being killed, except in the hard froſts of 1683 and 1739-40. In theſe two winters moſt of the Artichokes were deſtroyed in England; in the laſt of theſe winters, it happened from the little care which was taken of them, there having been no froſt for ſo many years before, which had injured them, that few people uſed any care to preſerve them; but after that hard froſt, many people ran into the other extreme of covering all the roots of Artichokes with long dung every winter, which is a very bad method, becauſe the dung lying near the roots is very apt to rot the beſt plants; therefore I would adviſe the earthing (or as it is called by the gardeners, landing) the Artichokes to be deferred till the latter end of november, or the beginning of december, provided the ſeaſon continues mild; and towards Chriſtmas, if there is any danger of ſevere froſts, to lay a quantity of long dung, Peaſe-haulm, tanners bark, or any other light covering over the ridges of earth, which will keep out the froſt; and this being at a diſtance from the roots, will not injure them; but this covering ſhould be carefully taken off the beginning of february, or ſooner, provided the ſeaſon is mild, or at leaſt ſo ſoon as the weather is ſo,

[h] Mor. hiſt. oxon. [i] Vahl.

otherwiſe the plants will be injured by its lying too long upon them.

It will alſo be a good method, whenever any roots of Artichokes are dug up in autumn, either to burn them deep in the ground in a pit till ſpring, or lay them in a heap, ſo as that they may be eaſily covered in hard froſts; and theſe may be a ſupply, if thoſe in the ground are deſtroyed.

When you have thus earthed them up, you have nothing more to do till february or march, by which time they will have grown through the ridge of earth; and, when the weather is proper, muſt be dreſſed as was before directed.

Spring Dreſſing.

At the end of february, in march, or the beginning of april, according to the earlineſs of the ſeaſon, or forwardneſs of the old Artichoke roots, will be the proper time for dreſſing them, which muſt be thus performed: with your ſpade remove all the earth from about your ſtock, down below the part from whence the young ſhoots are produced, clearing the earth from between the ſhoots with the hands, ſo as to be able to judge of the goodneſs of each, with their proper poſition upon the ſtock; then make choice of two of the cleareſt, ſtraighteſt, and moſt promiſing plants that are produced from the under part of the ſtock, which are much preferable to the ſtrong thick plants which generally grow upon the crown of the roots; for theſe having hard woody ſtems, never produce good fruit, but are generally what the market people call rogues, which have very little bottom, and the ſcales of their heads are irregularly placed; in ſlipping off the plants you muſt be careful not to injure thoſe which are to remain for a crop; then with your thumb force off all the other plants and buds alſo cloſe to the head of the ſtock, from whence they are produced, being very careful not to leave any of the buds, which will ſoon produce plants ſo as to hurt thoſe which are left: then with your ſpade draw the earth about the two plants which are left, and with your hands cloſe it faſt to each of them, ſeparating them as far aſunder as they can conveniently be placed without breaking them, obſerving to crop off the tops of the leaves which hang down with your hands; your ground being levelled between the ſtocks, you may ſow thereon a ſmall crop of Spinach, which will be taken off before the Artichokes will cover the ground, and be ſure to keep them clear from weeds; and toward the latter end of april, or the beginning of may, when your old plants begin to ſhew their fruit, you muſt carefully look over your ſtocks, and draw up all young plants from them, which may have been produced ſince their dreſſing, and cut off all ſuckers which are produced from the ſtems of the Artichoke, leaving only the principal head, by which means your fruit will be the larger; when your Artichokes are fit to gather, you muſt break or cut them down cloſe to the ſurface of the ground, that your ſtocks may make ſtrong freſh ſhoots before the end of october: the ſeaſon for earthing, or, as the gardeners term it, landing them up, is the middle or latter end of november, which is thus done:

Cut off all the young ſhoots quite cloſe to the ſurface of the ground; then dig between every ſtock, raiſing all the earth between each row of ſtocks into a ridge, as is done in the common method of trenching ground, ſo as that the row of Artichokes may be exactly in the middle of each ridge, this will be ſufficient to guard them againſt froſt; and I would here recommend it to the public, as infinitely preferable to long dung, which is by the unſkilful often uſed, and is the occaſion of their fruit being ſmall, and almoſt without any bottoms to them; for there is not any thing ſo hurtful to theſe, as new dung being either buried near, or laid about them.

Additional obſervations.

Though the Artichoke is perennial, yet after the third or fourth year the heads will become ſmaller, and leſs fleſhy: it is a good method, therefore, to make a freſh plantation every year, to ſucceed the old ones when worn out, and at the ſame time to inſure a ſucceſſion of heads from june to november; for the old plants are over by auguſt, and then the young ones come in. If, however, the Artichokes are ſuffered to remain more than three or four years in the ſame ſpot of ground, it ſhould be well manured in november with rotten dung, and dug a full ſpade deep.

If you are deſirous of having large heads, the ſmall lateral heads ſhould be cut off before they are the ſize of a hen's egg. The latter are by many much eſteemed for the table. When the heads are gathered, the whole ſtalk ſhould be broken down cloſe to the ground, to encourage the ſtools to produce new ſhoots before winter.

The method of earthing or landing the Artichokes before winter is, having firſt cut down all the large leaves to the ground, preſerving only thoſe of the ſmall young ſhoots, to mark out with a line the middle ſpace between the rows, and then to dig the ground a ſpade deep, gradually working the earth towards the row of plants, ſo as to make a ridge, raiſing the earth cloſe about the plants, but not entirely covering their tops. Some, however, only draw a little earth with a hoe about the plants, and when there is froſt throw a little long dung or litter over them; whilſt others do nothing more than lay ſome ſhort dry muck about each plant when hard froſts ſet in. Either of theſe methods are ſufficient in common winters; but in ſevere ones nothing can inſure them but effectually ridging up the earth about them as firſt directed, and covering the ridge with long dry litter.

3. The Chardon, or Cardoon, is propagated in the kitchen gardens to ſupply the markets; this is annually raiſed from ſeeds, which ſhould be ſown upon a bed of light earth in march; and when the plants come up, they ſhould be thinned where they are too cloſe; and if the plants are wanted, thoſe which are drawn out may be tranſplanted into a bed at about three or four inches diſtance, where they ſhould remain till they are tranſplanted out for good. Theſe young plants muſt be kept clean from weeds, and in the beginning of june they muſt be tranſplanted out, on a moiſt rich ſpot of ground at about four feet aſunder every way; the ground ſhould be well dug before they are planted, and the plants ſhould be well watered until they have taken new root, after which the ground muſt be kept very clean from weeds, to encourage the growth of the plants; and as they advance in height, there ſhould be ſome earth drawn up about each plant; and when they are fully grown, their leaves ſhould be cloſely tied up with a hay-band, and the earth drawn up in hills about each plant, almoſt to their tops, being careful to keep the earth from falling between the leaves, which may occaſion the rotting of the plants. The earth ſhould be ſmoothed over the ſurface that the wet may run off, and not fall into the center of the plants, which will alſo cauſe them to rot; in about eight or ten weeks after the plants have been thus earthed, they will be blanched enough for uſe; ſo that if a ſucceſſion of them are wanted for the table, there ſhould be but few plants earthed up at the ſame time; but once in a fortnight there may be a part of them earthed, in proportion to the quantity deſired.

Toward the middle, or latter end of november, if the froſt ſhould be ſevere, it will be proper to cover the tops of thoſe plants which remain with Peaſe-haulm or ſtraw, to prevent the froſt from penetrating to the tender leaves, which frequently pinches them where there is not this covering, but this ſhould be taken off again in mild weather; if this care is taken, the plants may be preſerved for uſe moſt part of the winter.

If a few of the plants are planted out in a warm ſituation to ſtand for ſeed, they ſhould not be blanched, but only in very hard froſt ſome light litter, or Peaſe-haulm, may be laid round them to keep out froſt, which ſhould be removed in the

ſpring,

ſpring, and the ground gently dug between the plants, which will not only deſtroy the weeds, but alſo encourage the roots of the plants to ſhoot out on every ſide, whereby their ſtems will be ſtronger: theſe will flower about the beginning of july, and if the ſeaſon proves dry, their ſeeds will ripen in ſeptember; but in cold wet ſeaſons, theſe ſeeds will not come to maturity in England.

[The ſtalk of the leaf, which is thick and criſp, and by many perſons thought palatable, is the part which is eaten; this is rendered white and tender, by blanching like Celeri, about a yard or more in length: the ſeaſon for it is autumn and winter, and it is uſed in ſalads, ſoups, ſtews, &c. It is, however, now in no great eſtimation here, and therefore not much cultivated.

As this plant does not bear removal very well, the general practiſe now is to ſow the ſeed where it is to remain, in baſins or holes eighteen inches over, and three inches deep, three ſeeds in each hole, thinning out afterwards the two weakeſt plants.

Obſerve not to tye up the leaves for blanching before they are full grown, unleſs they are wanted in ſeptember or october, in which caſe they muſt be tied up, and the earthing muſt be begun in auguſt, but then the ſtalk of the leaf will never be broad and thick, and in that conſiſts its chief excellence. The proper time to begin blanching is at the end of ſeptember or in october, when the plants will come into uſe in december, and continue all the winter.

Obſerve alſo to tie up the leaves in a dry day, to add freſh hay-bands as the plants advance in height, and to cover their tops with long litter if the froſt ſhould be ſevere.]

4. This may be planted in the ſame manner as the preceding, the plants being ſet three or four feet apart. They require only to be kept clean from weeds. They will flower the ſecond year, and if the ſeaſon prove dry, the ſeeds will ripen in ſeptember. They generally decay the following winter, eſpecially if it be ſevere, unleſs they are covered.

Arils baſket-ſhaped, ſmooth, ſtriated, tubercled, toothed on the edge, leaves hairy, tubercled, entire, root-leaves ſpatulate-lanceolate.

DESCRIPTIONS, *&c.*

1. The whole plant is downy, and ſoft to the touch. *Root* biennal. *Stem* two or three feet in height, upright, grooved-angular, villoſe, very leafy, branched at top: branches numerous, nearly upright, and villoſe. *Root-leaves* large, a foot or more in length, on petioles, ovate or lanceolate, pointed, covered with a ſilky down which gives them a grayiſh colour, veiny: *ſtem-leaves*, at leaſt the uppermoſt, ſeſſile, half-ſtem-claſping, quite entire, with a waving edge, ſeven or eight inches long, crowded, placed irregularly on the ſtem, upright, lanceolate, and broadeſt at the baſe. *Flowers* at firſt of a dull red, marone or mulberry colour; afterwards becoming blueiſh; growing in racemes, which are nearly upright, and generally naked, or without bractes; and all hanging one way. *Calyx*, ſegments ovate-lanceolate, upright, downy, bluntiſh, ſhining on the inſide. *Corolla*, tube half the length of the calyx: border concave, with roundiſh ſegments: throat perforated: ſquamules or nectareous ſcales anteriorly hollow, gibboſe at top, blunt, inſerted into the edge of the tube, half the length of the border, fringed. *Anthers* oblong, green, hid under the ſcales. *Germs* yellow, or yellowiſh green, ſmooth[a].—According to Scopoli, each raceme has one leaf at its origin; the nectareous ſcales are ſlightly emarginate; the ſtyle is an obtuſely quadrangular pyramid; the ſtigma is ſcored with a line along the middle; the arils or covers of the ſeeds are echinate.

It grows wild by road ſides, and in uncultivated places in moſt parts of Europe. With us it flowers in june and july, and ripens its ſeeds in autumn. The whole plant has a diſagreeable ſmell, much reſembling that of mice. It is ſuſpected to poſſeſs narcotic qualities; and an inſtance is related in the *Hiſtoria Oxonienſis* (3. 450.), in which the leaves, boiled by miſtake for thoſe of Comfrey, diſordered a whole family, and proved fatal to one perſon: others, however, will not admit the fact. It has formerly been uſed in medicine; and Mr. Ray informs us, from Dr. Hulſe, that a decoction of the roots inwardly, and cataplaſma of them outwardly, were uſed in ſtrumous and ſcrophulous caſes. It is, however, diſcarded from the preſent practice[b].

Cattle in general diſlike it; the Goat only is ſaid ſometimes to crop this nauſeous plant. Krocker affirms that all animals leave it untouched except ſheep, which exception muſt ſurely be a miſtake.

It is frequently found with a white flower. β. The large Dutch Hound's-tongue, which is double the ſize of the common ſort, is probably nothing more than a variety ariſing from luxuriancy of ſoil[c].

γ. Evergreen Hound's-tongue is a remarkable variety. The leaves are without nerves, are rougher and much narrower than the common ſort; but it has none of the hoarineſs of that, the leaves therefore are of a full green colour. It has none of that ſtrong ſcent which common Hound's-tongue has. The ſtem has a ſlight hairineſs. The flowers are blue and ſmaller[d].—In ſeveral parts of Germany and Switzerland. With us in the London road between Kelvedon and Witham, but more plentifully about Braxted: about Worceſter: about Southend by Eltham: beyond Waltham-abbey towards Harlow: Norbury near Leatherhead in Surrey. Flowering in april and may.]

2. This riſes with an upright branching ſtem near four feet high; this and the leaves are covered with rough hairs; the branches are ſpread out on every ſide, and are but thinly furniſhed with leaves, from three to near four inches in length, and little more than an inch broad in the middle, gradually leſſening to both ends; they embrace the ſtem, and are alternate. The flowers grow ſcatteringly towards the ends of the branches: they are ſmall and white, appear in june, and are ſucceeded by four ſmall ſeeds, which ripen in autumn, and then the plants decay.—Native of Virginia and other parts of North America.

[Linneus thinks that it is ſcarcely a diſtinct ſpecies from the foregoing, from which it differs only in having the upper ſurface of the leaves ſhining.

Cultivated in 1759, by Mr. Miller[e].

3. Root perennial, branched. Stems ſeveral, a foot high, round, branching; leaves half-ſtem-claſping, obverſely lanceolate, or ſpatulate, quite entire, covered on both ſides with a white ſilvery down, but having none of the tubercles, which occaſion the roughneſs in the firſt ſpecies. Flowers in racemes, without any bractes. Corollas white, with red, blue or purple veins[f].

Native of Silefia, Carniola, Italy, the South of France, Spain, Gibraltar, and the Levant. It flowers in june and july.

Cultivated 1596 by Gerarde. Biennial[g].]

4. The leaves of this are much larger, the petal of the flower much ſhorter, and the ſtature taller than the firſt ſort; it alſo flowers earlier.

[Gærtner thus deſcribes the ſeeds.—Four nuts, with a leathery cruſt, fixed to a pyramidal receptacle, of an ovate-acuminate form, flattiſh on the upper ſurface (which is even depreſſed in old ſeeds), muricated, with erect little prickles, but gibbous below and on the ſides, roughened with ſharp dots, pale ſtraw-coloured. Seed large, obovate-beaked, below the beak umbilicated, of a brown colour.

Native of the Apennines. Cultivated 1731, by Mr. Miller. It flowers from april to june, and is Biennial[h].

5. Stem erect, a foot in height, ſtriated, panicled at top. Root-leaves petioled, ſoft: ſtem-leaves ſmall, ſeſſile[i].

Nuts four, leathery-membranaceous, ſcutiform on the outſide. Shield ovate, broad, with a membranous edge, radiated with ferruginous lines. The nut itſelf placed in the concave part of the ſhield is ovate-globular, acuminate at top, with an oblong umbilical area in the middle, one-celled and valveleſs. Seed ovate, with a beak, ſomewhat compreſſed, dark-bay[k]. Native of Siberia.

6. This whole plant is very ſmooth. Stem erect, a foot high, round: branches axillary, alternate, quite ſimple. Leaves an inch long, gradually ſmaller upwards, blunt, veinleſs, glaucous-green, nearly of the ſame form with thoſe of Braſſica orientalis. Racemes from the end of the ſtem and branches, without bractes, a hand or more in length. Pedicels remote, filiform, an inch long, ſpreading very much. Calyx deeply five-cleft; ſegments lanceolate, two of them ſomewhat ſmaller than the reſt: they are a little larger than in C. linifolium, without any hairineſs. Corolla as in C. linifolium, with which this plant has been confounded, though they were diſtinguiſhed by Tournefort, the Linnean character agreeing indifferently to either, and being much alike in habit and ſtructure[l].

Native of Portugal. Cultivated in 1731, by Miller.]

[a] Curtis & Withering. [b] Ibid. Ibid. [c] Ray.
[d] Pollich & Withering. [e] Hort. kew.
[f] Krocker & Scopoli. [g] Hort. kew.
[h] Ibid. [i] Linn. ſuppl. [k] Gærtner. [l] Vahl.

7. This ſeldom riſes more than five or ſix inches high; the ſtalks do not branch near ſo much as thoſe of the preceding. The leaves are very narrow and long, of a grayiſh colour, and ſmooth. [The root-leaves are petioled, and wedge-ſhaped; the upper ones lanceolate, attenuated at the baſe, rugged, with very minute remote white toothlets about the edge [a]. According to Retzius, they are ciliate, eſpecially on the branches.] The flowers grow in ſhort looſe panicles at the ends of the branches; they are white, like thoſe of the preceding, but ſmaller; and have ſeeds of the ſame form, namely umbilicated, whence theſe plants derived the name of Navel-wort.

[Gærtner thus deſcribes the fruit:

Nuts four, ſmall, with a ſubulate receptacle, bent in as the ſeeds ripen, accumbent, ſomewhat membranaceous, compreſſed, ovate-acuminate, at the edge extenuated into a diaphanous, whitiſh membrane, deeply ſtriated, with a large toothed hole at top. Seed black brown.

Native of Portugal. Cultivated 1731, by Mr. Miller [b].]

8. Root perennial. Branches trailing, and putting out roots from the joints. Leaves bright green, on long ſlender foot-ſtalks. Flowers ſhaped like thoſe of Borage, but ſmaller, and of a lively blue colour.

[Flower-ſtem ſimple, half a foot in height, not creeping itſelf, but putting out long runners from the baſe, during ſummer. The leaves on that are oval, not cordate, as the root-leaves are. Racemes axillary, with very few flowers. Corollas ſalver-ſhaped, ſix lines in diameter, with a tube one line only in length, obtuſely pentangular: the throat has a white ſtar formed of five heart-ſhaped plaits: ſtyle cylindric; ſtigma hemiſphæric, of the ſame colour with the ſtyle. Receptacle with a rim round it. Capſules (or arils) ſomewhat villoſe, with an elliptic hole in the middle: ſeldom all fertile (which is alſo the caſe in the common Hound's-tongue). Sometimes there are two ſeeds in one capſule (or aril); and then the baſe of the capſule is two-celled [c].

Native of the South of Europe, in woods: flowering about Chriſtmas. Cultivated in 1633; and flowering here from march to may [d].

9. Root annual. Stems four or five, round, villoſe, flexuoſe and erect, unequal. Leaves ſtem-claſping, acute, very finely ſerrate, ſpreading; root-leaves near a finger's length; branch-leaves gradually ſmaller. Flowers terminating, in racemes. Calyx wholly villoſe. Corolla purple, longer than the calyx. Style ſimple, with an obtuſe ſtigma. Native of Japan [e].

10. Leaves much ſhorter, ſofter, and more hoary than thoſe of the common ſort. Stems a foot and half in height, more branched. Seeds ſmaller.

It reſembles the common ſpecies ſo much, that it is no wonder they have been confounded by thoſe who have not ſeen both. It agrees with *C. officinale* in habit, ſize, and manner of growth, but differs in having the leaves not narrowed at the baſe, but cordate [f]; and the flowers pale blue or pale purple, beautifully painted with darker veins. Perennial, and flowering in auguſt. Native of the South of Europe, and of Barbary; alſo of Madeira, where it was found by Mr. Maſſon; and whence it was introduced 1777 [g].] Mr. Miller ſays it grows naturally in Andaluſia, and that he received the ſeeds from Gibraltar.

11. This has the appearance of the common ſort, but differs from it in having all the leaves ſharp at both ends. Stem herbaceous, upright, angular, rough with hairs, hoary at top. Lower leaves drawn out into a petiole an inch in length; upper ones ſeſſile, veiny-nerved, the upper ſurface having dots and white hairs ſcattered over it, the lower aſh-coloured, with more crowded hairs, but not ſoft. Calyxes hirſute, with oblong ſegments [h].

Native of Egypt.

12. Root perennial. Stems uſually ſeveral, filiform, aſcending, ſcarcely half a foot high, hairy, uſually ſimple. Leaves rough, next the root petioled, on the ſtem ſeſſile, linear-lanceolate. Flowers in looſe ſpikes, pedicelled, erect, ſolitary. Calyx hairy, with ſubovate ſegments. Corolla very ſmall, ſcarcely longer than the calyx, blue; tube very ſhort; ſegments of the border rounded; ſcales cloſing the mouth, glandular. Arils, whilſt unripe, fixed to a pyramidal four-cornered receptacle. Seeds flatted, ovate, acute, ſmooth. Native of moſnt Libanus or Lebanon, on the very ſummit [i].]

PROPAGATION AND CULTURE.

1. The firſt ſort, being a common weed, is not admitted into gardens: it is ſometimes gathered in the fields by the herbariſts.

2 to 5, 10. Being hardy plants, where the ſeeds are permitted to ſcatter, they will ariſe plentifully without much care.

6, 7. Are annual plants, commonly ſown in gardens, with other low annual flowers, to adorn the borders of the flower-garden; but the ſeeds ſhould be ſown in autumn, for thoſe which are ſown in the ſpring often fail, eſpecially in dry ſeaſons; and the autumnal plants always grow much larger, and flower earlier. The ſeeds ſhould be ſown where the plants are deſigned to remain, for they do not bear tranſplanting, unleſs it be performed whilſt they are young. The plants require no other culture but to be thinned where they are too cloſe, and kept clean from weeds. They flower in june and july, and the autumnal plants come a month earlier. The ſeeds ripen in autumn.

8. This propagates very faſt by its trailing roots, which require to be kept within compaſs; on this account it ſeldom produces ſeeds. It delights in a moiſt cool ſituation.

DESCRIPTIONS, &c.

Theſe trees are natives of the Eaſt-Indies. Their leaves are conjugate; and the peduncles are many-flowered.

1. Roots knotty and large, appearing above ground, and having ſmaller ones between them, which are curled, and look like pig's tails. Trunk

[a] Vahl. [b] Hort. kew. [c] Scopoli. [d] Hort. kew. [e] Thunberg. [f] Vahl. [g] Hort. kew.

[h] Vahl. [i] Billardiere.

very short, seldom two feet high, very irregular, rugged, unequal, ugly, in hills and holes, covered with a thick, hard, cloven bark, the colour of Liverwort. The head is not large, but thick; it consists of thick long branches, subdivided into many others at the end, the extreme of which only bear the leaves: these are alternate, in pairs, on very short petioles, three or four inches long, and an inch and half wide, entire, smooth, firm, flexible, acuminate; rib straight, prominent on both sides, dividing the leaf into two very unequal segments. The flowers come out on the trunk and large branches, and on the root when above ground; the corolla is small and white [a].

The fruit is thus described by Gærtner. It is a Legume, fleshy, large, the size of half the palm of the hand and more, in the shape of a half moon, compressed like a lens, with a groove, like a suture, along its whole circuit, on the sides tubercled, rough to the touch like a woollen cloth, one-celled, not opening. Seed of the same shape with the cavity of the legume, smooth, marked with capillary arched vessels arising from the umbilicus, of a red ferruginous colour, fastened to the shell by a short thick chord at the middle of the straight suture. Skin single, leathery, thin, in old seeds scarcely separable from the kernel by boiling water. Albumen none. Embryo of the same shape with the seed, white: cotyledons plano-convex, with a little hole on the inside where the radicle is placed: plume slender, two-horned, with very short soft fulvous or red-ferruginous villose hairs about its base, by which the radicle is separated to the distance of half a line from the cotyledons: radicle conic, immersed, centrifugal.

2. This is a lofty tree, sixty feet in height; trunk thick, solid, ash-coloured; bark blackish, within red; branches many, ash-coloured or greenish. Leaves in a double parallel row, roundish, smooth, the upper surface dark green and shining, the lower paler green, with many small nerves from the mid-rib standing out, dividing the leaf unequally, and running obliquely to the sides. Smell none; taste subastringent. The flowers come out scatteringly from the small branches among the leaves; they are small, white, and without scent. Petals four, acuminate. Stamens eight, with red anthers. Fruit oblong, compressed, unequal, grooved, not unlike a gourd, covered with a thick, leathery, fleshy, soft rind, somewhat like that of the almond, opening on each side. Kernel whitish, compact, covered with a thin pellicle; it has no smell, and has an astringent taste.

In Malabar. It is always green, and bears flowers and fruits in august and november [b].

CYNOMORIUM. (*A canini genitalis similitudine. Mich.*)

Lin. gen. n. 1033. *Reich.* 1126. *Schreb.* 1394. *Mich.* 12. *Amen. acad.* 7. *p.* 357. *Juss.* 445.

Class. 21. 1. Monoecia Monandria.

Nat. order of *Amentaceæ*.

GENERIC CHARACTER.

* *Male flowers* disposed in an imbricated ament with the female ones.

Cal. *Ament* erect, club-shaped, on every side covered with floscules.

Perianth proper, four-leaved: *leaflets* three clavate, and the fourth inferior one larger, very obtuse, channelled.

Cor. none.

Stam. *Filaments* single, firm, straight, longer than the calycine scale. *Anther* twin.

* *Female flowers* mixed with the males in the same plant, and scarce remote from them.

Cal. *Ament* common with the males.

Perianth proper superior: *leaflets* four, club-shaped, tuberculated, equal, permanent.

Cor. none.

Pist. *Germ* ovate, inferior. *Style* single, erect, firm, spreading, length of the calycine scale. *Stigma* obtuse.

Per. none.

Seed single, roundish.

Obs. *I have also seen hermaphrodite monandrous florets intermixed with the others. The whole plant is a single ament.*

ESSENTIAL CHARACTER.

Male. *Cal.* an imbricate ament. *Cor.* none.

Fem. *Cal.* in the same ament. *Cor.* none. *Style* one. *Seed* one, roundish.

SPECIES.

1. Cynomorium coccineum.

Lin. spec. 1375. *Reich.* 4. 89. *amæn.* 4. 351. *t.* 2. *mat. med.* 199. *Mich. gen.* 17. *t.* 12. *Pet. gaz. t.* 39. *f.* 8. *Tilli pisan. t.* 25. *Bocc. mus.* 2. 69. *fic. t.* 81.

Stipe scaly, ament cylindrical, scales imbricate, ovate retuse.

2. Cynomorium jamaicense.

Swartz prodr. 12. *Brown. jam.* 334.

Stipe scaly, ament elongated, scales imbricate, halved, rhomboidal.

3. Cynomorium cayanense.

Swartz prodr. 12.

Stipe naked, ament subglobular, scales roundish, peltate.

DESCRIPTIONS, &c.

1. This is a fungiform plant, the whole consisting of a long, thick, radical spadix, growing upon the roots of trees in salt marshes, under water [c]. Stem commonly half a foot long, upright, solid, tough, as thick as the finger, when young covered with ovate, acute, imbricate, white scales, which it mostly puts off at flowering time, so as to be then almost naked, wrinkled, unequal, and the whole, when dried, purple. A spike terminates this stem, frequently as long as the stem itself, but twice its breadth, with scales or bractes, in the axils of which the flowers sit close [d].

Native of Barbary, on the coast, at the roots of Lentiscus, Myrtle, &c. Sicily, Malta, Cadiz, &c. on Halimus or Portulaca marina, &c.

2. It grows in beds, and rises generally to the height of three, four, or five inches; but is commonly smallest towards the bottom. At first it is covered pretty thick with scales of the figure of a heart, which fall off gradually as it rises, and expose the body of the plant thickly beset with little transparent denticles, intermixed with a few tubular trifid flowers, that jet above the level of the surface. The stem is succulent and fleshy, and all the parts astringent. Jamaica; seldom met with but in the most shady inland woods [e].

3. Native of Cayenne [f].

Cynomorium. See *Cynometra*.

Cynophallophorus. See *Capparis*.

Cynops. See *Plantago*.

Cynorynchium. See *Chelone*.

Cynosorchis. See *Orchis*.

CYNOSURUS, (κυων ουρα, *Dog's-tail.*)

Lin. gen. n. 87. *Reich.* 93. *Schreb.* 118. *Juss.* 31. *Gærtn. t.* 1. & Eleusine, *t.* 1.

Class. 3. 2. Triandria Digynia.

Nat. order of *Gramina*, *Gramineæ*, or *Gruminæ*.

GENERIC CHARACTER.

Cal. *Receptacle common* unilateral, (often) leafy.

Involucre (in some) one-leafed, lateral.

Glume many-flowered, two-valved: *Valves* linear, acuminate, equal.

Cor. two-valved: the *outer* concave, longer: the *inner* flat, awnless.

Nectary two-leaved: *leaflets* ovate, acute, gibbous at the base.

Stam. *Filaments* three, capillary. *Anthers* oblong.

Pist. *Germ* turbinate. *Styles* two, villose, reflex. *Stigmas* simple.

Per. none. *Corolla* closely coating over the seed, and not gaping.

Seed single, oblong, acuminate to each end.

[a] Jussieu. [b] Linn. amœn. [c] Brown. [d] Swartz.

Obs.

Obs. *The Involucres in moſt ſpecies are pinnatifid, or of a peſtinate form.*

In the different ſpecies the number of floſcules is different.

Eleuſine of Gærtner *differs in having the ſeed included in a membrane.*

ESSENTIAL CHARACTER.

Cal. two-valved, many-flowered. (two or four-flowered. *G.*) *Recept.* proper unilateral, leafy.

Spikes digitate, incurved, culm compreſſed, erect, leaves nearly oppoſite.

9. Cynoſurus ægyptius. *Creeping Dog's-tail graſs.*
Lin. ſpec. 106. *ſyſt.* 117. *Reich.* 200. *Lour. cochinch.* 59. *Pluk. alm. t.* 300. *f.* 8. *Mor. hiſt. ſ.* 8. *t.* 3. *f.* 7. *Schreb. gram.* 109. *Burm. ind.* 28. *Bont. jav.* 148. *Rumph. amb.* 6. *t.* 4. *f.* 1.

Spikes digitate, in fours, obtuſe, ſpreading very much, mucronate; ſtem erecting; leaves oppoſite.

10. Cynoſurus indicus. *Indian Dog's-tail graſs.*
Lin. ſpec. 106. *ſyſt.* 117. *Reich.* 201. *Vahl ſymb.* 2. 21. *Lour. cochinch.* 59. *Burmanzeyl.* 106. *t.* 47. *f.* 1. *Rumph. amb.* 6. *t.* 4. *f.* 2. *Rheed. mal.* 12. *t.* 69. *Forſk. ægypt.* 18. (Panicum).

Eleuſine indica. *Gærtn. fruct.* 8.

Spikes digitate, linear, culm compreſſed, declined, knotty at the baſe, leaves alternate.

11. Cynoſurus virgatus. *Fine ſpiked Dog's-tail graſs.*
Lin. ſpec. 106. *Reich.* 201. *amœn.* 5. 393. *Brown. jam.* 137. *Sloan. jam.* 1. 113. *t.* 70. *f.* 2.

Panicle with ſimple branches; flowers ſeſſile, ſix together, the laſt barren, the loweſt ſometimes awned.

12. Cynoſurus domingenſis.
Lin. ſyſt. 117. *Jacqu. miſc.* 2. 363.

Panicle with ſimple branches, ſpikelets ſubſeſſile, ſix-flowered, all the flowers awned.

13. Cynoſurus aureus. *Golden-ſpiked Dog's-tail graſs.*
Lin. ſpec. 107. *Reich.* 201. *Murr. prodr.* 138. *Shaw. afr. f.* 232. *Barr. rar.* 1180. *t.* 4.

Gr. panic. pendula aurea. *Bauh. pin.* 3. *theat.* 33. *Schreb. gram.* 149.

Panicles with barren pendulous ternate ſpikelets, flowers awned.

14. Cynoſurus erucæformis. *Linear-ſpiked Dog's-tail graſs.*
Ait. hort. kew. 105.

Phalaris erucæformis. *Lin. ſpec.* 80. *Gmel. ſib.* 1. *t.* 29. *Barr. rar.* 1158. *t.* 2.

Spike compound, ſpikelets ſcattered, the fruit-bearing ones erect, calyxes one and two-flowered, glumes obtuſe, boat-ſhaped, keel obtuſe; corollas acuminate.

15. Cynoſurus retroflexus.
Vahl ſymb. 2. 20.

Spike compound, ſpikelets aggregate, calyxes two-flowered, awned, corollas awnleſs.

16. Cynoſurus filiformis.
Vahl ſymb. 2. 20.

Spike ſolitary diſtich, calyxes awl-ſhaped, three-flowered, barren floret awnleſs.

17. Cynoſurus monoſtachyos.
Vahl ſymb. 2. 20.

Spike terminating, calyxes awl-ſhaped, awnleſs, ſubtriflorous, florets awned, one-ſided.

18. Cynoſurus penicillatus.
Vahl ſymb. 2. 21.

Spikes digitate, calyxes four-flowered, awned at the back, outer petals of the hermaphrodite awned, with bearded penicils.

19. Cynoſurus paſpaloides.
Vahl ſymb. 2. 21. *t.* 27.

Spikes digitate, calyxes two-flowered, ſubglobular, outer valve of the calyx awned, corollas awnleſs.

20. Cynoſurus floccifolius.
Vahl ſymb. 1. 10. *Forſk. ægypt.* 21. *n.* 73.

Spikes linear, ſtraight, leaves doubled together, alternately bearded on the edge.

DESCRIPTIONS, &c.

1. *Root* perennial. *Culms* from one to two feet in height, erect, ſtrict, having three or four joints, ſmooth and even. *Leaves* narrow, flat, ſmooth on both ſides, ſcarcely rough at the edge: *ligule* ſhort, ſlender, truncate, cloven, with the edge a little prominent: *ſheaths* ſtriated, ſmooth and even. *Spike* com-

compound, when in flower ſemicylindric, facing one way, obtuſe: when out of flower interrupted, awnleſs. *Rachis* flexuoſe, twiſted. *Pedunculs* ſhort, ſolitary, alternate, unilateral, in a double row; having three ſpikelets (ſometimes five), and always three *bracteæ*, which are feathered, from convex flat, and ſubſeſſile, made up of an axis which is ſomewhat flexuoſe, and ſeven or nine pinnules: each, when magnified, has the appearance of a diſtich ſpikelet, with ſubulate, alternate, compreſſed, awned, ſcabrous valves. *Spikelets* two-flowered, rarely three-flowered, ſmaller than the bracteæ. *Calyx* ſlightly unequal, keeled, mucronate; the outer valve remote from the other at the baſe, bowed upwards, more ſcabrous. *Florets* ſlightly awned. *Anthers* red or purple. *Styles* naked at the baſe [a].

According to Pollich, the leaves are near half a foot in length, above two lines in breadth, and roughiſh if the fingers be moved from the point towards the baſe. Ligule entire. Panicle (or ſpike) three or four inches in length, and as many lines in breadth. Outer valve of the glume has an awn at the end ſcarcely a quarter of a line in length. Stigmas white, feathered.

Common in dry paſtures; flowering in july and auguſt, and called *Bent-graſs*, in common with many others: in Scotland *Windleſtraw-graſs*. Moſt modern writers, ecchoing Stillingfleet, have celebrated this graſs as excellent for ſheep. Mr. Curtis juſtly thinks leſs favourably of it, and conſiders it as greatly inferior to many other graſſes. It is predominant on ſheep downs, and in many parks, but is late and unproductive.

Mr. Ray (ſyn. 399. 3.) ſets down a variety of this, which he calls *Square Creſted-graſs*, becauſe the ſpike has four rows of flowers. It was found by Mr. Dale, in the fields at Notley in Eſſex.

2. Raceme glomerate, pointing one way. Bractes only on the outſide of the flowers, alternately pinnate, one-flowered, the rays ending in an awn. Calyx two-flowered, membranaceous, very much attenuated at the tip. Corolla has a ſtraight awn on the outer tip. Style bifid [b].

According to Gærtner, the calyx is ſometimes three-flowered, very thin, oblong, acuminate; the corolla ſomewhat rigid, the inner glume flattiſh, acuminate, the outer concave, awned below the tip; awn briſtle-ſhaped, ſtraight, twice as long as the calyx. Seed oblong, acuminate at both ends, pubeſcent at the tip, convex on one ſide and ſmooth, concave on the other, marked with an obſcure raiſed line, bay-colour or ruſeſcent.

Villars remarks, that it is ill-named *echinate*, for the ſpike is rather lanuginoſe, than beſet with prickles: he adds, that it is ſometimes very tall among the corn, and that he has ſeen it on a rock only two or three inches high.

Native of Europe and the Levant.—Near Sandwich, and in Jerſey, in a ſandy ſoil, flowering in july. Annual.

3. Scarcely a ſpan in height. Leaf ſmall, the ſheath ſwelling a little. Spike cloſely imbricate, oblong, compoſed of ſeſſile flowers, compreſſed and keeled, directed one way, in a double row: the outer calycine valve is compreſſed, and larger than the other: each flower conſiſts of five florets [c]. Culms ſlender, upright. Leaves ſhorter than the ſheath, acute, the edges rolled inwards as they advance in age ſo as to appear ruſhy. Spike ſolitary, an inch and half long. Calyx one or two-flowered: valves awl-ſhaped, long, the outer keeled, compreſſed, and longer than the other. Outer valve of the corolla keeled, ſharp, inner ſhorter, flat. Seed oblong, ſharp at both ends [d].

Native of Spain; flowering in may. Annual. With us it flowers in july and auguſt.—Introduced in 1776, by M. Thouin [e].

4. Culms few, ſcarcely a palm in height, procumbent. Leaves even. Spikelets in two rows, pointing the ſame way, without an involucre; they are ſtiff, three-flowered, linear, obtuſe, even. Florets compreſſed, awnleſs [f]. Culms many, a finger's length, very ſtiff. The upper leaves longeſt. Flowering-ſpike ſtraight, ſtiff, compoſed of imbricate, hard, compreſſed, lanceolate ſpikelets. Calyx awnleſs, ſmooth, ſhorter than the petals, with unequal glumes. Petals alſo unequal: one obtuſe, the other acuminate. Styles two or three. There is a third or fourth flower, often incomplete. The plant when adult, is entirely of a brown or bay colour [g].

Scopoli not finding any character of this genus in it, has removed it to the Poas: and Pollich, though he leaves it with the *Cynoſuri*, approves the removal.

Native of the ſouthern parts of Europe: in Carniola, Switzerland, the Palatinate, Sileſia, and other parts of Germany. Annual, flowering in may and june; with us in july.—Introduced 1776, by Monſ. Thouin [h].

5. Root, culms and leaves as in *C. cæruleus*, except that the culm is much more tender, and ſomewhat ſhorter; the leaves three or four times narrower, flat, and of a paler colour. The ſpike reſembles a head of Garlic. Univerſal involucre three-leaved: leaflets membranaceous, ſeſſile, ſuborbicular, concave, jagged-toothed at top, in the other parts entire, very pale blue, turning whitiſh, and becoming tranſparent. Spikelets imbricate every way, and ſubſeſſile. Calyx two or three-flowered; glumes nearly equal, at firſt longer than the corolla, but afterwards ſhorter, blue, with white edges, ending in a ſort of creſt, and ciliate on the middle of the back. Outer valve of the corolla larger, blue, white, and membranaceous on the edge, ciliate along the middle of the back, ending in three little creſts of the ſame colour, the middle one twice or thrice the length of the others. Inner valve ſhorter, flattiſh, with blue edges, forked, with two greeniſh keels along the middle of the back. Native of the Alps. There is a variety with white flowers in larger heads [i].

6. Culms oblique, ſurrounded at the baſe with a bundle of root-leaves incloſed in a whitiſh brown wrinkled ſkin, giving the appearance of a branched root; above bare of leaves. Panicle reſembling a ſpike, of an ovate-oblong form. Florets on ſhort peduncles, purpliſh, livid, or browniſh white, from half an inch to an inch in length. Involucre roundiſh, embracing the ſtalk, gnawed, membranaceous, ſhorter, but thrice as wide as the calyx; the lower one at the baſe of the ſpike, the other a little higher up at the baſe of the florets of the oppoſite ſide. Calyx moſtly two-flowered, ſometimes juſt longer, and ſometimes juſt ſhorter than the florets; edges and keel bearded. Valves of the corolla equal, with the edges and keel bearded: outer with five ribs, four-toothed, ending in awn-like points, the two middle ones ſhorter, with the keel running out from between them into a ſhort awn twice as long as the teeth. Anthers whitiſh, cloven at the baſe. Germ reddiſh brown. Seed hairy [k].

To this we may add, that the root is perennial; the culms ſlender, from two to ſix inches, and a ſpan in height, having three joints, with a very ſhort leaf at each. Leaves bluiſh ſea-green, from half an inch to three inches in length, keeled, and rough along the edges. Spike of a reddiſh purple colour, ſometimes browniſh white, or entirely white. Calyx, though uſually two-flowered, has ſometimes one, and ſometimes three florets. Anthers deeply cloven at both ends, yellow except at one end, where they are purple.

There is much diſſention about the genus of this graſs. Jacquin made it an *avena*; and Scopoli obſerves, that in its manner of flowering it reſembles that genus, but that it has the appearance of Anthoxanthum, and is very nearly allied to the Phleums:

[a] Leers. [b] Linn. ſyſt. [c] Linn. ſpec. [d] Cavanilles. [e] Hort. kew. [f] Linn. ſpec. [g] Scopoli. [h] Hort. kew. [i] Jacquin. [k] Stokes in Witharing.

he made it a diſtinct genus, under the name of *Sclleria*, and has been followed by Scopoli, Arduini, Withering, &c.

Native of Europe in mountainous and boggy paſtures. In the north of England, on the higheſt lime-ſtone rocks, as Ingleborough, &c.

The firſt notice of it we have is from Mr. Ray, who received it from Mr. Petiver, to whom it was ſent out of the north, by Mr. Fitz-Roberts. It flowers the earlieſt of all our graſſes. In the ſpring of 1792 the ſpikes were puſhing vigorouſly on the 16th of march, and it was in full flower on the 29th. This would recommend it for culture, if it were not of low growth. Foreign authors deſcribe it as being larger than we find it to be.

7. A very ſmooth graſs, with the appearance of *Uniola*, but the calyx is bivalved, not many-valved. Spike linear. Spikelets ſeſſile, preſſed cloſe to the rachis, in two rows, alternate, ſpreading at the ſides, oblique, very ſmooth, many-flowered.—Native of the Cape of Good Hope [a].

8. Annual. Culms four feet high, covered with leaf-ſtalks. Leaves long, in two rows, the edge and upper ſurface, eſpecially towards the ſauces, viſhoſe with a few long hairs; ſheaths oppoſite, compreſſed, ſtem-claſping. Spikes four or ſix, terminating, (ſometimes one below) ſtriated, almoſt erect, the length of the finger; as they ripen growing broader, and often bent in. Rachis of the ſpikelets depreſſed, with the flowers alternate on the inſide, ſeſſile on the outſide. Flowers ovate-oblong, compreſſed, awnleſs, preſſed cloſe to the rachis. Calyxes four-flowered, the inner valve lower and ſmaller, but both compreſſed and keeled, like the corolla. Seeds nearly globular, large, in four rows, ſwelling, naked.—Native of India [b], and Japan, where it is cultivated for the eatable ſeeds [c].

According to Gærtner, one globular, ſmooth ſeed, of a ferruginous red colour, is covered by an ovate-globular, membranaceous, thin, diaphanous, one-celled, valveleſs capſule.

It flowers from july to ſeptember; and was cultivated in 1714, by the Dutcheſs of Beaufort [d].

9. Culm even, ſlender, long, pale, jointed, bent and procumbent at the joints, ſmooth, and very tough, with many ſhort upright branches. Leaves awl-ſhaped. Spikelets four or five, horizontal, with a mucronate rachis extended beyond the flowers, which are alternate and diſtich. Calyxes two-flowered and awnleſs. Valves of the calyx acuminate, keeled, unequal [e].

Native of Aſia, Africa, and America. Annual; flowering from july to ſeptember. Introduced 1770, by Monſ. Richard [f].

10. Culm ſlender, almoſt upright, reddiſh, ſometimes creeping, leafy. Leaves many, ſmall, ſtiff [g]. Spikes heaped, linear, four or ſix from horizontal ſpreading, from a thick baſe growing gradually more ſlender to the top, floriferous at bottom. Valves of the calyx acute; the inner longer, ciliate, lanuginoſe. Capſule and ſeed reſembling the eighth ſpecies, only one-third leſs in all the parts. It differs abundantly, not only from this, but all other known genera of graſſes, in having a real and very conſpicuous pericarp.—*C. ægyptius*, though like this in external appearance, is not of this genus [h].

Linnæus remarks, that after the ſeeds fall, there remain pectinate ſpikes, with calycine glumes, of which the ſide ones ſpread open with a rugged keel: and that the calyxes contain about four flowers.

Vahl obſerves, that this Graſs varies with more and fewer, longer and ſhorter ſpikes; and that the lower leaves are frequently oppoſite.

Annual. Native of both Indies; (Japan and the Society Iſles.) Cultivated 1714, by the Dutcheſs of Beaufort. It flowers in auguſt [i].

11. Height two feet and a half, with a ſpreading panicle at the top, generally compoſed of many delicate ſlender ſimple ſpikes. Native of Jamaica [k].

Cultivated 1727, by Mr. Miller. It flowers from july to ſeptember; and is perennial [l].

12. Root perennial. Culms ſeveral, erect, from two to three feet high, round, ſmooth, ſhining, ſlender, jointed, leafy, frequently putting out a ſingle branch from one of the lower joints, otherwiſe quite ſimple. Leaves enſiform-linear, acute, flat, feeling rough when the finger is drawn along the edge from point to baſe, hairy on the upper ſurface below the middle, ſmooth on the lower; ſheath ſomewhat hirſute. Panicle upright, filiform, compoſed of ſeveral very ſpreading alternate or oppoſite branches forming a ſort of raceme, defended at their origin by a bundle of hairs; on the alternate toothleſs of theſe branches ſit ſmall compreſſed ſpikelets in a double row. The calyx contains from three to five florets, without any other involucre; valves keeled, prickly at the back, acute, awnleſs, upright, permanent, one ſhorter than the other. Outer valve of the corolla like the calycine glume, but awned, inner flat and awnleſs. Awn purple, rough, from the top of the back part of the valve; gradually ſhorter in the upper flowers. Stigmas very dark purple. Seed minute. It flowers and ſeeds in the ſtove during the whole year.

Native of St. Domingo in the Weſt Indies [m].

According to Swartz, this is nothing more than a variety of *C. virgatus*, which has often ſpikelets with and without awns growing promiſcuouſly in dry ſoils of the Eaſt Indies. The glumes have from three to ſix flowers; the branches of the panicle are filiform or thicker; and the flowers are more or leſs ſeſſile. The habit of this is more tender and lax [n].

13. Spikelets ternate, barren; calyx bivalved, linear, acuminate, involving many ſolitary, alternate, ovate, obtuſe, concave glumes, without the ſmaller valve ſtamens or piſtils; they cannot therefore be well called flowers, but are rather involucres: at the baſe of the ſpikelets are two flowers, with a linear calyx the length of the florets which are two together, the lower ſeſſile; the outer glume is ovate, with a long ſtraight awn coming out below the tip; the inner glume is very narrow. The other floret, on a peduncle the length of the former floret, is very like that, but ſmaller: there is the rudiment only of a third floſcule.—Native of the South of Europe, among ſtones and rocks, and of the Levant. Annual [o].

Introduced 1770, by Monſ. Richard. It flowers in july [p].

14. It reſembles *Paſpalum*, but the valves of the flower gape in a contrary manner [q].

Native of Ruſſia and Hudſon's Bay. Introduced 1773, by Monſ. Richard. It flowers in july, and is annual [r].

It is obſerved by Dr. Stokes (With. arr. 95.) that in the *C. criſtatus, echinatus* and *aureus* there are generally only two florets in a calyx; that in the *cærulens* and *aureus*, the little ſpikes are inſerted on different ſides of the ſpike; and that in the *durus, coracanus, ægyptius* and *indicus*, the receptacle cannot be ſaid to be leafy, as in theſe the involucre is wanting. The *durus* is truly a Poa; and the three others have the habit of Panicum, with the ſtructure of Poa, forming a natural aſſemblage of their own. The *Cynoſuras* therefore, as a natural genus, ſeems to be confined within the limits of *criſtatus, echinatus*, and *aureus*.

New Species from Vahl.

15. Culms round ſmooth. Leaves awl-ſhaped, a ſpan long, ſmooth. Ligule membranaceous. Spike a ſpan long, upright. Common rachis grooved, angular. Spikelets in threes at each tooth of the rachis, the lateral ones ſeſſile, the middle one on a ſhort pedicel, all linear, an inch long, a little longer than the interſtices, ſpreading; ſometimes, but ſeldom, a fourth ſpikelet, which is ſeſſile and a little

[r] Hort. kew.

above the others, all bent back when old. Flowers on one side of the rachis, compreſſed, ſmooth. Partial rachis flexuoſe. Valves of the calyx lanceolate, attenuated very much into a briſtle, hence as it were awned. Corollas in pairs, one pedicelled.—Station between the 4th and 5th ſpecies.

16. Culms creeping, branched, filiform, compreſſed at bottom; internodes an inch long. Floriferous ſcapes from the top, a ſpan long, quite ſimple, jointed, having a ſingle awl-ſhaped leaf towards the middle. Leaves at the joints ſeveral on each ſide, an inch and half in length, briſtle-ſhaped. Sheaths compreſſed, equitant, nearly the ſame length with the leaves, and broader. Spike an inch long, linear. Flowers ſmall, alternate, compreſſed, ſmooth. Valves of the calyx, ſpreading, nearly equal, the length of the florets, acute. Florets uſually three, one ſeſſile hermaphrodite, a ſecond pedicelled male, a third barren. Outer valve of the corolla awned below the tip in the male and hermaphrodite, awnleſs in the barren floret. Awn a little longer than the calyx.

The ſtation of this and the three following is between the 7th and 8th ſpecies.

17. Culm upright, a foot and half high, ſmooth. Leaves awl-ſhaped, narrow. Spike ſolitary, a ſpan long. Rachis convex and keeled on the outſide. Flowers alternate, imbricate, on the inner ſide, ſmooth. Valves of the calyx awl-ſhaped; the outer larger than the length of the florets, the inner ſhorter. Florets bearded at the baſe and compreſſed: hermaphrodite ſeſſile, male ſmaller, the third barren: outer valve of all keeled, awned below the tip: awns ſtraight, twice as long as the calyx.

18. Culm round, upright, very finely ſtreaked, pubeſcent at top. Spikes in threes, but ſometimes ſolitary, on very ſhort pedicels, bearded at the baſe, four or five inches long, upright, ſometimes a little recurved at the end. Rachis ſomewhat convex on the outſide, channelled within. Flowers from the inner ſide only, ſeſſile, alternate, very much crowded, awl-ſhaped, ſlightly compreſſed, ſpreading. Inner valve of the calyx lower, ovate, acuminate, almoſt tranſparent: outer ſuperior, lanceolate, attenuated, three times the length of the inner one, compreſſed, keeled, having a groove on the back, ciliated in a raiſed line on each ſide by the groove; awn on the middle of the valve, upright, the length of the valve. Florets four, bearded at the baſe: two hermaphrodite, the outer petal bearded at top with two pencils, and ciliated with white long very ſoft hairs; awn half an inch long, ſtraight: two flowers ſmaller, one of them awnleſs; probably theſe are males.

Theſe four ſpecies are natives of the Eaſt Indies.

19. Culm very ſimple, almoſt leafleſs, a foot high. Root-leaves ſheathing, linear-lanceolate, two inches long, ſharpiſh. Sheaths compreſſed, equitant, twice as broad as the leaves. Spikes five, ſeſſile, an inch and half long and more, woolly at the baſe, linear, narrow, ferruginous, ſhining. Flowers on one ſide, the ſize of millet ſeed, alternate, crowded, very blunt. Outer valve of the calyx ſhorter than the corolla, ovate, awned a little below the tip, emarginate, keeled; the other ſmaller. Florets in pairs, longer than the calyx, the outer valves keeled, the keel and whitiſh edge ciliate.

Native of the Cape of Good Hope: obſerved there by Bulow.

20. The limits between this and the other digitate Cynoſuri are determined with difficulty. In habit it approaches very near to C. coracanus. It differs from them all in having the ſingle leaves folded together and alternately bearded. On the inner ſide of the leaf towards the edge is a minute oblong hole, and oppoſite to this on the outſide a ſpot, both yelloviſh, the margin of the leaf, which is rolled in, is cut out between theſe two ſpots, and all this part is clothed with ſoft white hairs in bundles. The ſheaths are not ciliate, nor the leaves hairy. The ſpikes and ſpikelets are longer and narrower than in C. coracanus, and the valves of the florets ſharper.—Native of Egypt*.

PROPAGATION AND CULTURE.

Several of the ſpecies are natives of the Weſt Indies, and more of the Eaſt Indies. Few of theſe are known in Europe otherwiſe than by ſpecimens or deſcriptions. They muſt be propagated by ſeeds brought from their native places of growth; and kept in the bark ſtove. Thoſe from the Cape of Good Hope, &c. are preſerved of courſe in the dry ſtove. For the culture of the European ſorts, particularly the firſt, ſee GRASS.

Culm round, umbel compound involucred, ſpikes lanceolate, glumes mucronate.

35. Cyperus arenarius.
Retz. obſ. 4. *n.* 11. See n. 7.
Culm compreſſed naked, ſpikes of the head glomerate ſeſſile, involucre one or two-leaved.

36. Cyperus capitatus.
Retz. obſ. 4. *n.* 12.
Culm ſubangular ſtriated leafy in the middle, head terminating three-leaved, ſpikes ſeſſile.

37. Cyperus ſtoloniferus.
Retz. obſ. 4. *n.* 13.
Culm naked three-cornered, umbel compound involucred, ſpikelets lanceolate.

38. Cyperus Pangorei.
Retz. obſ. 4. *n.* 14. *Rotth. deſcr.* 31. *t.* 7. *f.* 3.
Culm three-cornered leafy at the baſe, involucre three-leaved, univerſal umbel decompound, partial ones ſubtrifid.

39. Cyperus cinnamomeus.
Retz. obſ. 4. *n.* 15.
An C. ligularis. *n.* 46. *Rottb. t.* 11. *f.* 2?
Culm three-cornered leafy, umbel conſiſting of ſpikelets in a head peduncled and ſeſſile, involucre five-leaved ſerrulate-ſcabrous.

40. Cyperus ſetaceus.
Retz. obſ. 5. 10. *n.* 6.
Culms ſetaceous ſtriated-angular naked, ſpike terminating with about four flowers and naked.

41. Cyperus compactus.
Retz. obſ. 5. *n.* 7.
Culm round leafy, umbel decompound, involucre five-leaved, ſpikelets heaped ſubſpiral.

42. Cyperus mucronatus.
Retz. obſ. 5. *n.* 8. *Rotth. deſcr.* 19. *t.* 8. *f.* 4?
Culm round? naked, ſpikes lateral ſeſſile, involucre one-leafed.

43. Cyperus diphyllus.
Retz. obſ. 5. *n.* 9.
Culm ſubtriangular two-leaved, umbel ſuperdecompound, ſpikelets roundiſh ſubpinnate.

44. Cyperus leucocephalus.
Retz. obſ. 5. *n.* 10.
Culm ſetaceous three-cornered naked; head ſeſſile; involucre four-leaved or thereabouts, ſpreading very much; flowers one-ſtamened.

45. Cyperus exaltatus.
Retz. obſ. 5. *n.* 12.
C. faſtigiatus. *Rotth. deſc.* 32. *t.* 7. *f.* 2.
Culm three-cornered one-leafed at the baſe, umbel ſuperdecompound, many-leaved, ſpikelets linear pedunculed.

46. Cyperus niveus.
Retz. obſ. 5. *n.* 13.
Culm three-cornered filiform naked, umbel terminating ſeſſile two-leaved, ſpikes compreſſed lanceolate.

47. Cyperus imbricatus.
Retz. obſ. 5. *n.* 14.
Culm three-cornered naked, umbel decompound, rays of the umbellules imbricate, involucre ſix-leaved with three leaves very long and three very ſhort.

48. Cyperus cruentus.
Retz. obſ. 5. *n.* 15.
Culm three-cornered one-leafed at the baſe, umbel terminating two-leaved very ſimple.

49. Cyperus nitens.
Retz. obſ. 5. *n.* 16.
Culms three-cornered leafy at the baſe, umbels almoſt ſimple, involucre three-leaved, flowers one-ſtamened.

50. Cyperus flavidus.
Retz. obſ. 5. *n.* 17.
Culm three-cornered ſtriated, umbel compound three-leaved, ſpikes lanceolate, flowers one-ſtamened.

51. Cyperus venuſtus.

52. Cyperus ſtuppeus.

53. Cyperus linctus.
Forſk. fl. auſtr. app. n. 495, 496, 497.

DESCRIPTIONS, *&c.*

Moſt of the ſpecies have three-cornered culms or ſtems. The flowers in aggregate peduncled and umbelled ſpikes. The lower chaffs are ſometimes empty[a].

1. Root tuberous, red, having a very grateful ſmell like that of *Calamus aromaticus*. Stalk three feet high, ſmooth, with very ſtrong and frequent tranſverſe partitions or membranes. At the top ſeveral brown chaffy panicles, made up of ſmall, long ſpikes.

Native of Jamaica, in the rills of the Savanna, beyond two-mile wood[b]: and in Egypt on the banks of the Nile.

The Egyptian plant differs from that of the Weſt Indies only in having ſhorter ſpikelets, ſometimes eight-flowered, and paler. Forſkall ſays that the culms are not jointed, probably in the freſh plant the joints may be leſs conſpicuous, but in the dry ſpecimens certainly the culms are jointed[c].

2. Roots compoſed of many capillary brown fibres, whence ariſe many ſmall narrow leaves, an inch long, and reddiſh underneath. Stalks many ſimple, triangular, about two inches high, (three or four, *Browne*,) with two or three ſmall ſhort leaves towards the top. Above theſe, uſually three ſmall ruſty ſcaly ſpikes or heads, two whereof have ſhort peduncles, and the other none: they are ſufficiently diſtinguiſhable by their ſmallneſs[d].—Native of Jamaica, and Braſil.

3. Culms the length of a needle, many, briſtle-form, not ſtiff. Spike ovate, ſcales from ſeven to nine, diſtich, ſomewhat ſharp, ſmooth and even, ſeſſile its own length below the tip of the culm. Annual.—Native of the Cape of Good Hope[e].

4. Culm ſmooth and even, leafleſs. Leaves very long, cutting downwards by means of little prickles on the edge; in other parts, and even on the keel, ſmooth. Involucre ſix-leaved, very long. Spikelets ovate, ferruginous.

Native of India, now found wild in Italy.—Perennial[f].

5. Culm not a finger's length, the thickneſs of a horſe-hair. Spikes below the top of the culm, compreſſed, ancipital, ovate, even, with ten or twelve ſcales.—Native of the Cape of Good Hope[g].

Perhaps the ſame with the third.

6. Root-leaves numerous, linear, very narrow, even, looſe, a ſpan in length. Culm filiform, weak, ſcarcely a foot high. Spike imbricate, compreſſed a little, even, the ſize of a cucumber ſeed, with keeled, mucronate ſcales. A ſubulate leaflet, ſometimes two, under the ſpike, and of the ſame length with it[h].

This, according to Swartz, is rather the loweſt glume, not longer than half the ſpike; which he deſcribes as being imbricate in a double row, with the two loweſt ſcales longer than the others, linear, awl-ſhaped, keeled, the others broader, the uppermoſt acuminate: there are little briſtles between the ſcales near the keel. Germ three-cornered: ſtyle three-ſided, trifid at the end: ſtigmas reflex. Seed white, calloſe with dots.

Native of the Eaſt and Weſt Indies.

7. Culms even, two feet high. Leaves two, ſtiff, convolute-ſubulate; the upper one broad at the baſe, concave, produced from the tip of the culm, three or four times as long as the head; the lower immediately under it, reflex, half the length of the other. Head terminating, roundiſh, compoſed of ſeveral ſeſſile ſpikelets. Involucre two-leaved.

[a] Juſſieu. [b] Sloane. [c] Vahl. [d] Sloane. [e] Linn. ſuppl. [f] Ibid. [g] Ibid. [h] Linn. mant.

Spikes or flowers oblong-ovate, imbricate, bluntiſh, with ovate ſcales. Perennial.—Native of Coromandel in the Eaſt Indies [1].

8. Culm a foot high, lax, yellowiſh, ſtriated, tender. Leaves linear, ſtriated, yellowiſh dotted with brown, longer than the culm. The general involucre conſiſts of two leaves like thoſe on the culm; the largeſt one-third longer, the ſmaller three times ſhorter than the umbel. The partial involucre conſiſts of lanceolate ſcales at the ſubdiviſions of the partial umbel and the baſe of the ſpikes. Principal rays of the umbel about twenty, ſpreading, unequal, filiform. Rays of the ſecond diviſion twelve to fifteen, ſpreading very much, ſo as to be almoſt horizontal. Rays of the third diviſion, when there are any, five or ſix, only half an inch long, and even ſhorter. In the fourth or laſt ſubdiviſion ſpikes three to ſix, expanded in a ſtar. Spikes linear, compreſſed, diſtich, tender and very delicate, one-third of an inch long, ſcarcely half a line broad; ſcales imbricate, very ſmall, compreſſed, alternate, diſtant, bluntiſh or truncate, ferruginous, dotted, ſixteen to twenty in each ſpike [2].

Native of India, Ceylon and the Cape. Perennial.

9. Root long odoriferous. Peduncles ſometimes twelve, umbelled, the rays gradually ſhortening to the middle, the outer one half a foot in length. Spikelets corymbed, ſlender, acuminate, cheſtnut-coloured [3].

Native of France, Germany, Italy, Sicily, and Carniola, in bogs, marſhes and ditches. Found by Mr. Newton, in the iſle of Purbeck, Dorſetſhire, and by Canon Holcombe near St. David's. Perennial; flowering in july.—Called Engliſh Galingale.

The root is agreeably aromatic to the ſmell, warm and bitter to the taſte. The modern practice diſregards it; but perhaps it is not inferior to ſome of the more coſtly medicines brought from abroad [4].

10. Roots fibrous, with ſmall round tubers or bulbs hanging from them the ſize of Peas or Beans, of a ſweetiſh taſte, ſomewhat like Cheſtnuts. Stems about eighteen inches high. Shorter and ſmaller in all the parts than the next ſpecies.

Native of the country about Montpellier, Italy, Sicily, and the Levant. Perennial [5].

11. Culm ſcarcely a foot high, having at bottom four alternate leaves. Panicle of many naked peduncles, each of which produces four or five diſtich, oblong ſpikes, almoſt linear, with one in the middle on a very ſhort peduncle, furniſhed in the ſame manner with ſpikelets. Involucre of two or three leaflets the length of the umbel. The root bears ſome bulbs [6].—Native of Arabia, India, Ceylon, Japan.

The Cyperus, n. 36. of Flora zeylanica, and hexaſtachyos of Rottboll, which are the ſame, are ſuppoſed to be different from the C. rotundus of the materia medica.

12. Culms ſeveral, one or two inches high, filiform, three-ſided. Leaves linear-briſtle-ſhaped, longer than the culm, embracing the baſe of it with purple ſheaths, when young glaucous, when old ferruginous. Involucre of four leaves, ſeldom three or five, alternately ſhorter, longer than the umbel, ſpreading, reſembling thoſe on the culm. Bractes ſmall, ovate, at the baſe of each ſpike. Umbel bifid or trifid; middle umbellule ſeſſile; ſide ones two ſometimes three, very ſhort, ſubſeſſile, naked, commonly on divaricate peduncles almoſt the length of the central umbellule. Spikes ſeveral, linear, acute, ſtriated, ſquarroſe, diſtich, radiating, alternate. Scales commonly ten to fourteen, lanceolate, very ſharp, compreſſed, keeled, reflex at the end, ſomewhat hairy, ferruginous or gray, with the keel green [7].

Native of Tranquebar, and the Cape of Good Hope.

13. Culm three-ſided, flaccid, very weak, a foot high, having two linear ſoft leaves, two inches long, of a browniſh green colour, above the baſe, in other parts naked [8]. Involucre two-leaved, one of the leaflets very long. Spikes numerous, ſeſſile, lanceolate, with ovate, concave, obtuſe ſcales, ſcarioſe on the ſide [9].

Native of India.

14. Peduncles in the umbel very many, umbelluliferous at top; umbel of three or four rays alternately bearing ſpikelets of three-cornered and very obtuſe grains, covered with a ſcarcely diſcernible chaff, and little diſtant from each other [10]. Umbel ſimple, many-rayed: ſome of the peduncles ſhort, others very long, panicled with alternate ſpikelets, each floſcule remote from another, which makes it an elegant plant [11].

Native of India, China, and Japan.

15. This is a large plant, with an even culm. Umbel unequal. General involucre many-leaved, very long; partial ſhorter than the ſpikes, which are all ſeſſile, ferruginous, compoſed of tender, diſtich ſpikelets.

Native of India [12].

16. This has ſo much the ſtructure of the preceding, that perhaps it may be the ſame, only become ſhorter by growing in a colder climate. Spikes heaped and conglomerate, not elongated. This plant, together with Phalaris oryzoides, and Andropogon alopecuroides, was probably brought originally from India to Italy with rice.—Native of Italy [13].

17. Culm a palm in height. Root-leaves erect, wholly ſmooth, the length of the culm. Involucre three-leaved, longer than the culm, except three ſubulate leaflets which are ſhort. Umbel ſimple, with alternate ſeſſile flowers at top, the loweſt pedicelled. Flowers ovate, compreſſed, imbricate in two rows, growing brown by age [14].—In wet places about Verona, and in Piedmont. Annual.

18. Root-leaves from two to three feet and an half in length. Stalk two feet and an half high, with two or three leaves on the top, one whereof is a foot long. Panicle very ſparſe and elegant, made up of many ſpikes, ſome on peduncles three or four inches long, ſome on none, and others of all intermediate lengths; ſpikes compreſſed, broad, one-third of an inch in length, made up of two rows of ferruginous imbricate ſcales.

Native of Jamaica, in the ſea-marſhes, Liguanee [15]. Alſo of the iſland of Santa Cruz.

19. Root long, roundiſh, frequently jointed, reddiſh on the outſide, very odoriferous, creeping and making a large tuft, whence riſe many leaves with a prominent ſharp cutting keel. Stalks two or three feet high, with ſeveral ſmaller leaves towards the top, under the panicle, which is very ſparſe, having, beſides ſome ſhorter ſpikes, many on peduncles, above ſmall leaves, ſome whereof are a foot high; each of the ſpikes being long, very ſmall, roundiſh, pale green.—By river ſides in Jamaica, and moſt of the Caribees [16]. Alſo in Surinam, and the Society iſles.

20. This is known by its green panicle and ſpikes; by its mucronate glumes, not ſpreading, but the ſide edges membranaceous. The partial umbels naked, the univerſal glomerate [17].

Native of Malabar, Jamaica, Virginia, *&c.* in ſandy paſtures.

In the American plant the involucre is *three-leaved*; in that of Malabar *four-leaved*; in that of Ceylon *five-leaved*, and the leaves long [18].

The Jamaica plant is thus deſcribed by Swartz. Culms in a tuft, half a foot high or leſs, three-ſided, naked. Leaves from the baſe of the culm, linear, ſtraight, ſtiff, even. Involucre terminating, three-leaved; leaflets ſpreading, linear, keeled. Umbel decompound. Spikelets ſeſſile, pale green. Peduncles very ſhort, three or four, three-ſided, ſheathed at the baſe. Spikes imbricate in two rows;

[1] Linn. mant. and Rottb. [2] Rottb. [3] Scopoli. [4] Withering. [5] Linn. [6] Linn. syst. [7] Rottboll. [8] Rottb. [9] Linn. [10] Linn. spec. [11] Thunberg. [12] Linn. amoen. [13] Ibid. [14] Linn. mant. [15] Sloane. [16] Ibid. [17] Linn. spec. [18] Retz.

glumes compreſſed, keeled, membranaceous at the edge, ovate, acute but not mucronate. Briſtles two, whitiſh, between the ſcales. Anthers bifid. Style trifid: ſtigmas reflex. Seed roundiſh three-cornered, ferruginous and ſhining.

According to Rottböll, the culm is a foot high and ſtriated. Leaves at the baſe about three, ſoft, ſhorter than the culm, glaucous, with purple ſheaths. Involucre of four leaves, of which the largeſt is almoſt twice the length of the umbel. Partial involucres none. Umbel ſimple: rays unequal, from an inch and half to three inches in length, filiform, terminated by digitate ſpikes in fours, with one ſeſſile umbellule in the middle. Spikes lanceolate, diſtich, compreſſed on the ſides, almoſt four-ſided, from three quarters to an inch in length. Scales concave, lanceolate, compreſſed, acuminate, green ſtreaked with purple.

21. Fibres of the root loaded with little tubers. Culms obtuſely three-cornered, ſmooth, from an inch to a hand and a ſpan in height. Root-leaves ſpreading, ſmooth, keeled, two or three inches long, mucronate; beſides theſe there are two or three under the umbel of unequal lengths, narrower than the others, and longer than the umbel. Spikes ſeveral, of different lengths, forming a conglobate umbel, uſually trifid; ſometimes however only one or two ſpikes are ſeſſile at the top of the culm, and then there are only two involucral leaves: the ſpikes are much flattened, and at firſt are of a yellowiſh green, but turn yellow [d].

Native of France, Germany, Switzerland, Carniola, Piedmont.—Biennial, flowering from july to ſeptember. Introduced 1776, by Monſ. Thouin [e].

22. It ſcarcely differs apparently from the foregoing, in having narrower brown ſpikelets, and the leaves more ſcabrous [f].

Culm regularly three-cornered, thicker, higher, and not ſo ſhining. Panicle looſer and more branched. Seed ovate, not ſubcordate and pounced with ſmall holes, as in the foregoing [g]. Spikelets black, ſmaller, and more in number; it agrees with *C. flavescens* in every thing elſe [h]. Root annual. Culms a ſpan in height, ſmooth, with two or three leaves at the baſe, which are keeled, ſmooth and the length of the culm. Involucre three-leaved, the loweſt leaf as long as or longer than the culm, the two others longer than the umbel, ſometimes there is a fourth which is very ſhort. Peduncles three-cornered, ſheathed at the baſe: the middle one very ſhort, covered with ſpikelets: theſe are lanceolate-linear, compreſſed, dark brown, and have nine, eleven, or thirteen flowers in each. Glumes keeled, ſharp. Style cloven into two or three. Seed naked [i].

Native of Denmark, France, Germany, Switzerland, Carniola, Piedmont, Egypt. It flowers from july to ſeptember, and was introduced in 1777, by Mr. Thomas Blackie [k].

23. This reſembles C. compreſſus, but is ſhorter, and has the glumes leſs imbricate, and mucronate at the tip. Involucres longer than the umbels. Spikelets ſcarcely alternate and almoſt digitate [l].

Culm about three inches in height, with a few leaves at bottom. Involucre three-leaved, unequal. The head is compoſed of ſeſſile ſpikes, the larger of which have often one or two ſmaller ones at the baſe. Spikelets oblong, compreſſed, bay-coloured, compoſed of from ſixteen to twenty ovate keeled glumes; the keel green continued into a point [m].—Native of India.

24. Culms even, a foot high. Involucre terminating, two-leaved, ſhorter than the ſpike, ſubulate. Spikes terminating, ovate, compreſſed, ancipital, even, acute, with acuminate ſcales; peduncles of the ſide ones longer than the ſpike.—Native of the Eaſt Indies. Perennial [n].

25. Root roundiſh. Culm ſtriated, ſmooth, ſheathed with leaves at bottom, a foot high. Leaves channelled, entire, ſmooth, ſhorter than the culm. Involucre many-leaved, leaves from five to ſeven, unequal, longer than the umbel. Spikes about eight [o]; longiſh, ferruginous, very numerous, horizontal or even deflex [p].

Retzius ſuſpects that this is a ſpecies of Kyllingia.

Native of Barbadoes, Virginia, and Japan, in marſhes.

26. Leaves many, three feet long, near an inch broad at bottom, ending in a point, and making a large tuft. Stalks as thick as the finger, three feet high. Involucre of leaves two feet long, with ſeveral ſhorter. Spikes on three-cornered peduncles of different lengths from ſix inches, ſome branched into two or three, all of which have ſome ferruginous, ſcaly, round, pointed ſpikelets, made up of imbricate ſcales, ſticking cloſe to the tops of the peduncles. Seed browniſh-red and ſhining.

Native of Barbadoes, near Bridgetown [q]. Alſo of Guinea.

27. Involucre eight-leaved, the four outer leaflets broader. Univerſal umbel nearly equal, very copious, with the rays ſheathed at the baſe. Involucels erect, the length of the univerſal umbel. Umbellules with the peduncles in threes, and very ſhort. Spikelets many, alternate, ſubulate, ſeſſile [r].

Native of Egypt, Syria, Calabria, Sicily. According to Strabo, in the lake Thraſimene near Perugia.

Papyrus was called by the Greeks Biblus: in Egypt it has the name of el Berdi, and in Syria it is ſaid to be known by the name of Babeer, which approaches near to the ſound of papyrus and paper.

The general figure of this plant, as Pliny has rightly ſaid, reſembles a Thyrſus; the head is compoſed of many ſmall graſſy filaments, each about a foot long. About the middle, each of theſe filaments parts into four, and in the point, or partition, are four branches of flowers: the head of this is not unlike an ear of wheat in form, but in fact is but a chaffy, ſilky, ſoft huſk. Theſe heads, or flowers grow upon the ſtalk alternately, and are not oppoſite to, or on the ſame line with each other at the bottom.

Pliny ſays the Papyrus has no ſeed. It is very ſmall, and by its exalted ſituation, and thickneſs of the head of the flower, ſeems to have needed the extraordinary covering it has to protect it from the violent hold which the wind muſt have upon it. For the ſame reaſon the bottom of the filaments compoſing the head are ſheathed in four concave leaves, which keep them cloſe together, and prevent injury from the wind getting in between them.

The ſtalk is of a vivid green, and of a triangular form. It has but one root, which is large and ſtrong. Pliny ſays, as thick as a man's arm; ſo it probably was when the plant was fifteen feet high; but the whole length of the ſtalk, comprehending the head, being little more than ten feet, in the plants we now find, it is leſs in proportion. In the middle of this long root ariſes the ſtalk at right angles, the whole inverted having the figure of a T. From each ſide of the large root proceed ſmaller claſſic ones (or fibres) in a direction perpendicular to it, and which, like the ſtrings of a tent, ſteady it and fix it to the earth at bottom. About two feet or little more of the lower part of the ſtalk is cloathed with long, hollow, ſword-ſhaped leaves, covering each other like ſcales, and fortifying the foot of the plant: they are of a duſky brown or yellow colour.

It grows in the lakes of Ethiopia and Egypt; in the river Jordan between Paneas, and the lake or Tiberias; and at the confluence of the Tigris and Euphrates: but it was probably not propagated into Aſia and Greece, till the uſe of it, as manufactured into paper, was firſt known. It does not grow in the body of the Nile itſelf, but in the calmiſhes or places into which the river overflows and is ſtag-

[d] Scopoli, Poſſich, Krocker. [e] Hort. kew. [f] Linn. ſpec. [g] Scopoli. [h] Pollich. [i] Leers. [k] Hort. kew. [l] Linn. amoen. [m] Gærtner. [n] Linn. mant. [o] Thunberg. [p] Linn. ſpec. [q] Sloane. [r] Linn. ſyſt.

nant. The head is too heavy, the ſtalk too ſlender, tall and feeble, the root too ſhort and ſlender, to reſiſt the violent preſſure of wind and current in an open plain country, and a deep rapid river.

The Papyrus ſeems to have come down very early from Ethiopia, and to have been uſed in upper Egypt immediately after the diſuſe of hieroglyphics. According to Varro, it came not into general uſe in Greece, till after the conqueſt of Egypt by Alexander; yet it is plain from Anacreon, Alcæus, Æſchylus, and the comic poets, that it was known in their time. Plato and Ariſtotle ſpeak of it, and ſo do Herodotus and Theophraſtus. We alſo know that it was of old in uſe among the Ionians, who probably brought it in very early days directly from Egypt. Numa, who lived three hundred years before Alexander, is ſaid to have left a number of books written on Papyrus.

The ancients divided the plant into three parts. The top, with the thyrſe of flowers, adorned the temples, and crowned the ſtatues of the gods. Ageſilaus preferred being crowned with this to any other, on account of its ſimplicity. Antigonus made uſe of nothing elſe but the ſtalk for ropes and cables to his fleets, before the uſe of Spartum was known; which, though very little better, ſtill ſerves that purpoſe in ſmall ſhips on the coaſt of Provence to this day. The top of the Papyrus was likewiſe uſed for caulking the veſſels, by forcing it into the ſeams, and afterwards covering it with pitch.

Pliny tells us that the whole plant together was uſed for making boats, a piece of the Acacia-tree being put in the bottom to ſerve as a keel

"Conſcritor bibula Memphitis cymba papyro."

And this is ſtill the only boat which they have in Abyſſinia; they call it Tancoa. Probably the junks of the Red ſea, ſaid to be made of leather, were firſt built with Papyrus and covered with ſkins.

The bottom, root or woody part of this plant, before it turned hard, was chewed for the ſweet juice contained in it. This is ſtill practiſed in Abyſſinia, where they likewiſe chew the root of Indian corn, and of every ſort of Cyperus. Herodotus tells us, that about a cubit of the lower part of the ſtalk was roaſted over the fire and eaten.

On account of the great ſcarcity of wood in Egypt, this lower part was likewiſe uſed in making cups, moulds, and other utenſils; alſo for boards or covers to their books.

Paper was made after the following manner: the thick part of the ſtalk being cut in half, the pellicle between the pith and the bark, or perhaps the two pellicles were ſtripped off, and divided by an iron inſtrument, which probably was ſharp-pointed, but did not cut at the edges. This was ſquared at the ſides ſo as to be like a ribband, then laid upon a ſmooth table or dreſſer, after being cut into the length that it was required the leaf ſhould be. Theſe ſtripes, or ribbands, were lapped over each other by a very thin border, and then pieces of ſame kind were laid tranſverſely, the length of theſe anſwering to the breadth of the firſt. A weight was then laid on them while moiſt; and they were thus left to dry in the ſun.

It was ſuppoſed that the water of the Nile had a gummy quality in it; but this is without foundation: the ſaccharine juice of the plant cauſes the adheſion of the ſtripes, and the water only ſerves to diſſolve and diffuſe this [t].

Paper, ſays the Abbé Rochon, is manufactured in Madagaſcar from the Papyrus, which the natives call *Sanga-Sanga*. They pull off with great dexterity the inner bark; divide it into very thin filaments, which they moiſten with water; and having laid them acroſs each other, in various directions, preſs them well down. They are then boiled in a ſtrong lye of aſhes, and afterwards pounded in a large wooden mortar till they are reduced to a paſte. This paſte is waſhed and drenched with water upon a frame made of bamboos in the form of a grate. When this operation is finiſhed, the leaves are ſpread out to dry in the ſun, and are glazed with a decoction of rice water. This paper is of a yelloviſh colour; but when it is well glazed, it does not imbibe the ink. The pens uſed by theſe iſlanders are made of the bamboo. Their ink is made from a decoction in boiling water of the bark of a tree, which they call *Arandrato*. It is not quite ſo black as ours, but more ſhining. The art of writing was doubtleſs brought into the iſland by the Arabs, who made a conqueſt of it about three hundred years ago. But the Abbé Rochon calls the Papyrus nilotica a tree! We cannot therefore tell what material this Madagaſcar paper is made of.

28. Size of the Sugar-cane. Sheaths large, one-leafed, alternate, deciduous, involving the flowering racemes. Native of Virginia and the Cape of Good Hope. Perennial [u].

29. Perennial. Culms a foot high. Leaves at the top crowded, enſiform, half a foot long, even, roughiſh at the edge. A ſmall ſubulate bracte from each axil. A filiform peduncle, four times ſhorter than the leaf, from the axil of each leaf, terminated by an ovate ſpike. A few pedicels ſpring from the baſe of the ſpike, bearing at top a ſimilar ſpike: and therefore no umbel [x].

Native of the iſland of Madagaſcar. It flowers in february and march; and was introduced in 1781, by Monſ. Thouin [y].

30. Culm two feet high, with one ſheath in the middle of it. Umbel compound, not much expanded. Univerſal involucre with the rays ſcarcely manifeſt, and indeed hardly any; partial none. Spikes oblong, purpliſh, with a green keel, ſpreading a little at top.

Native of the Cape of Good Hope [z].

31. Root tuberous. Culm two feet high, three-ſided, ſtriated, yelloviſh. Leaves alternate, lanceolate, keeled, reflex, glaucous, inveſting the lower half of the culm with their ſheaths. General involucre of ſeveral lanceolate unequal leaves, the largeſt of which are much longer than the umbel. Partial involucres two to four-leaved, linear or linear-briſtle-ſhaped, ſhorter than the umbellules. Central umbelluſe in the firſt and ſecond diviſion ſubſeſſile: rays of the firſt diviſion about ten, unequal, the largeſt a ſpan long, the leaſt ſcarcely an inch and half: rays of the ſecond diviſion about five, an inch and half and two inches long: rays of the third diviſion about three, lengthened out into peduncles having ſpikes their whole length, of which the middle one is longeſt, being almoſt two inches long, and ſometimes trifid. Spikes about ten, looſe, very ſlender, ſpreading out horizontally, almoſt an inch long: ſcales many (about twenty-eight), very ſmall, alternate, ſpreading, oblong, bluntiſh, ferruginous with a ſtriated green keel. It varies with much ſhorter ſpikes, and an umbel only twice divided, or even ſometimes ſimple [a].

Native of Malabar.

32. Root annual. The whole plant ſmooth and ſhining. Culms in a very thick tuft, from half an inch to ſix inches in length, leafleſs. Root-leaf ſheathing, much ſhorter than the culm, linear, channelled. Involucre of two, ſeldom of three leaves, unequal, longer than the ſpikelets; which are ovate-oblong, in a ſort of umbel, blunt, compreſſed, ſlightly incurved. Scales membranaceous, roundiſh, blunt, pale with green ſtreaks. Seeds pale bay, ſmooth [b].

Native of Hungary. Flowering in july and auguſt. Annual. Introduced 1781, by Abbé Pourret [c].

33. Native of Jamaica. Flowering from may to auguſt. Perennial. Introduced 1781, by Monſ. Thouin [d].

34. Root-leaves filiform, twice as long as the culm, which is ſtriated and ſcarcely an inch and

[t] Bruce Abyſſ. vol. 5. p. 1, &c.

[u] Linn. ſpec. [x] Linn. mant. [y] Hort. kew. [z] Linn. ſuppl. [a] Rottboll. [b] Jacquin. [c] Hort. kew. [d] Ibid.

half

half in height. Umbel with five or ſix umbellulate peduncles. Spicules of the umbellules four to ſix, lanceolate, compreſſed, pale, in the middle reddiſh brown, with keeled glumes, ending in a ſmall daggered point. Involucre four-leaved, three times as long as the umbel.

Native of the ſands of Tranquebar.

Is not this the ſame with C. ſquarroſus of Rottböll: and is not C. ſquarroſus of Linnæus (n. 12.) a different plant?

35. Roots jointed, creeping, from which proceed bunches of leaves ſheathed at the baſe. Leaves filiform, naked, from three to ſix inches long, compreſſed, ſtriated, channelled on one ſide, yelloviſh green. Culm ſolitary from the bunch of leaves, ſtriated, and ſomewhat higher than the leaves. Head ſeſſile compoſed of ſpikelets from eight to twelve. Spikelets thick, compreſſed, diſtich, compoſed of broad-ovate, boat-ſhaped, ſtriated, brown ſcales edged with white. Involucre longer than the head, compreſſed; there is often another leaf ſhorter than the head.

Native of the Eaſt Indies in looſe ſand [e].—This ſeems to be the ſame with C. lævigatus, n. 7.

36. Culm four inches long, compreſſed, with a leaf or two at the baſe, and a bunch of leaves in the middle; thoſe at the baſe much broader, and a little higher than the culm. Head globular, compoſed of ſeſſile linear-oblong ſpikelets. Glumes imbricate, ſcarioſe, ending in a recurved daggered point ſomewhat awned.—Probably native of the Eaſt Indies [e].

37. Root bulbous. Leaves narrow, linear, complicate, a hand or half a foot in length. Culm a ſpan in height. The umbel has only one ſubſeſſile umbellule, and about three that are peduncled, having from three to five ſpikelets, which are red, and have imbricate glumes. Involucre one or two-leaved, the longer an inch and half in length, the ſhorter half an inch long. Beſides theſe there is another leaf or two ſtill ſhorter; they are all ſubulate and ſtriated:—Native of Tranquebar in the Eaſt Indies [f].

38. Culm two feet and an half high. Leaves long, unarmed, looſe. Peduncles of the umbellules flexuoſe. Involucre longer than the umbel. Scales in place of the partial involucre lanceolate, with a long filiform tip. Spikelets not filiform, but compreſſed, and linear.

Native of Tranquebar [e].

39. Root annual. Culms three feet high and more, ſolitary, leafy at the baſe, naked above. Leaves longer than the culm, near half an inch broad, plaited, with an unarmed keel; edge of the upper part rough. Leaves of the involucre plaited, with the keel unarmed; the outmoſt from one and an half to two feet in length, the reſt ſhorter, and the fifth only two inches long. Umbel formed of compound heads, three on compreſſed peduncles; five or more ſeſſile, with a ſubulate involucel under each. Heads ovate, compound, cinnamon-coloured. Spikelets heaped, compreſſed, diſtich, linear. Scales oblong, imbricate, obtuſe, the keel green; theſe are from ſix to nine in number [h].

40. This very much reſembles *Scirpus acicularis*. Culms in bunches three or four inches long, very ſlender. Leaves none. Glumes purpliſh. Style trifid. Seed whitiſh, turbinate, ſomewhat wrinkled; the angles riſe above the ſeed with a truncate dagger-point.—Frequent about Calcutta.

41. Culm two feet high and more. Leaves nearly as long as the culm, linear, with purpliſh ſheaths, the edge and keel unarmed, ſtriated. The longeſt leaf of the involucre a foot and half in length, the ſhorteſt three inches, all ſcabrous about the edge. Umbellules three or five-rayed. Involucels the number of the rays, ſhorter than the heads, ciliate. Heads compact of very ſpreading ſpikes, of a linear-ſubulate form, and ferruginous colour. Spikes ſeſſile, half an inch long, a line broad, ſeem twiſted, uſually ſix-flowered. Scales ſubulate with converging edges, ſtriated, purpliſh with a green keel. Stigmas three, villoſe.—Sent from China by Oſbeck [i].

42. Culms a foot high, with brown truncate ſheaths at the baſe. One or two root-leaves, ſhort and narrow. Head compoſed of a few ſeſſile ſpikes placed an inch and half from the end of the culm. Involucre ſcarcely longer than the ſpikes. Scales ovate, acute, convex, whitiſh.—Native of Viſagapatnam, in the Eaſt Indies [k]. Compare Rottb. 19. t. 8. f. 4.

43. Culm ſix feet high. Umbel terminating, four inches long. Involucre of many ſhort, acute leaves. Peduncles compreſſed. A lanceolate, whitiſh, involucel under each partial peduncle. Spikelets acute, pale, having about twelve flowers. Scales imbricate, ovate, acute, ſtriated. Styles three, with villoſe ſtigmas.—Eaſt Indies [l].

44. Root bulbous, oblong. Culms half a foot high. Leaves even, half the length of the culm. Head ſmall, ſnow-white. Spikes eight to twelve ſeſſile, broad-ovate. Scales linear, compreſſed, the loweſt long, the upper ones gradually ſhorter, obtuſe, ſtriated. Stigmas three villoſe. Seed long, linear, black.—Eaſt Indies [m].

45. Culm five feet high, ſtriated. Root-leaf near three feet long, flat, ſtriated, rough about the edge. Umbel more than a foot high, faſtigiate. Involucre many-leaved; the longeſt leaf two feet in length, the others decreaſing to an inch, all rough about the edge. Umbellules many-rayed, the rays unequally divided and compounded: involucels unequal in number, ſhort, filiform. Spikelets compreſſed, ferruginous on the ſides, having twenty flowers in them: there are two minute ſcales at the baſe of the pedicels. Scales compreſſed, acute, keeled. Seed white.——Tranquebar in the Eaſt Indies [n].

46. Culms a foot and half in height, ſtriated. Root-leaves few, ſhort, narrow; ſheath entire, with a ſhort, obtuſe ligule, oppoſite to the leaf. Umbel compoſed of ſnow-white ſpikes, uſually ſeſſile. Involucre reflex, longer than the head. Spikes half an inch in length, with thirty flowers in ſome. Glumes compreſſed, keeled, ſtriated. Seed black, like Buckwheat.—Eaſt Indies [o].

47. Umbel unequal, four inches long; ſome of the umbellules ſeſſile, others on peduncles of three inches and an half in length. No involucels. Spikelets convex on both ſides, compreſſed longitudinally in the middle, lanceolate, ſcarcely two inches long, having from twelve to twenty flowers, yellowiſh brown and pedicelled. Scales imbricate, broad-ovate, acute, with membranaceous edges. Stamen one. Stigma trifid.—Tranquebar, in the Eaſt Indies [p].

48. Culm four or five inches high, filiform. Leaf linear ſhorter than the culm. Spikelets from two to ten, lanceolate, ſanguineous-brown, two or three lines long. Involucre two-leaved, four times as long as the umbel. Scales imbricate, boat-ſhaped, bluntiſh. Stigmas three duſky purple. Seed convex on both ſides, dark purple, with a ſharp edge.—Tranquebar [q].

49. Culms many, an inch or two in height. Leaves two to four, linear, longer than the culm. Umbel glomerate; ſome of the ſpikes ſimple, others forming an almoſt ſeſſile umbellule. The longeſt leaf of the involucre an inch and half in length, the others gradually ſhorter. Spikelets linear, narrow, ſhining, whitiſh but longitudinally brown in the middle, with the ſcales diverging at top, and from ten to fourteen flowers. Scales ovate, compreſſed, keeled, ſtriated, hyalinous with a green keel, obtuſe with an acumen. Stamen one. Seed aſh-coloured. This approaches to *C. ſquarroſus*, but the ſpikelets are of a different colour, twice as broad with the tips of the ſcales ſhorter and leſs divaricated;

[e] Retz. [f] Ibid. [g] Ibid. [h] Ibid.

[i] Retz. [k] Ibid. [l] Ibid. [m] Ibid. [n] Ibid. [o] Ibid. [p] Ibid. [q] Ibid.

nor are the partial umbels peduncled.——Tranquebar[1].

50. Culms half a foot in height, one-leafed. Root-leaves in bunches, short, narrow. Some spikes of the umbel feſſile, others in umbellules. Involucre erect, three or four times as long as the umbel, linear. About twenty-ſix flowers in the ſpikes. Scales ſcarioſe, purpliſh on the ſides, ſeparate, narrow.—From Tranquebar[1].

Theſe were all ſent from the Eaſt Indies, by König, and are deſcribed by Retzius from the dried ſpecimens.

51, 52, 53. are natives of the Society iſles[2].]

PROPAGATION AND CULTURE.

9. 11. Cyperus longus and rotundus may both be propagated by dividing the roots in the ſpring. The firſt of theſe, if planted in a warm ſituation, will thrive in the open air. The ſecond being more tender, the roots ſhould be planted in pots, and ſheltered in winter. [Very few others have yet been introduced into cultivation here. Moſt of them are natives of the Eaſt or Weſt Indies, and therefore will require the protection of the bark ſtove.

Roots fibrous, leaves oblong at the root.]

DESCRIPTIONS, &c.

1. Root compoſed of many fleſhy black fibres, ſpreading obliquely near the ſurface; the fleſhy part retaining the mark of the ſtalk produced the former year: a new root being annually formed on the ſide of the old one. Stalks two, three or more, in proportion to the ſtrength of the root, nine, ten or twelve inches high, and a little hairy. Leaves from three to near four inches long, and near two inches broad at their baſe, of a deep green, and ending in acute points. Four or five of theſe leaves are placed alternately along the ſtalk. In the boſom of the upper leaf is incloſed the flower-bud, ſupported by a ſlender peduncle, which generally turns a little on one ſide; and before the flower opens, advances above the ſheath. The corolla has four narrow petals, of a dark purple colour, placed in form of a croſs, and ſpreading wide open. In the centre is ſituated the nectary, ſhaped like a wooden ſhoe, of a pale yellow colour, with a few broken ſtreaks: the opening is covered with two ears; the upper one tender, white, and ſpotted with purple; the lower thick, and of an herbaceous colour[1].

[The lower leaves ſheath, the upper embrace the ſtem; they are marked with ſeven or nine principal parallel nerves, and very numerous intermediate ones, fringed with ſhort hairs on both ſides. Upper part of the ſtem and the germ downy. No bracte, unleſs the upper leaf, from the boſom of which the peduncle ariſes, be called ſo. The upper petal broad, the two middle ones narrow, the loweſt ſhorteſt, hanging over the opening of the lip, all longer than the lip, ſlightly downy, marked with parallel veins; lip very large, curved, rounded at the bottom, and the margins contracted, pale yellow within, marked with deep orange hairy lines. Seed-veſſel erect, about an inch long, ſomewhat priſm-ſhaped, with three flat ſides, and three ribbed angles[2].

Native of Lapland, Sweden, Switzerland, Savoy, Piedmont, Germany, Hungary, Poland, &c. In the north of England, in woods and thickets, but rare.—Parkinſon and Ray remarked it to grow in Helk's wood, Lancaſhire, near Ingleborough, Yorkſhire: but Mr. Woodward has ſearched for it there in vain; a gardener of Ingleton having eradicated every plant for ſale.] Mr. Miller found it in the park of Borough-hall, in Lancaſhire, the ſeat of the late Robert Fenwick, Eſq.—[About Clapham and Ingleton in Yorkſhire. In the neighbourhood of Kilnſay; and about Kilſey-Crag, Wharfdale, both in Yorkſhire; and Caſtle-Eden-dene in the county of Durham.—Gerarde had a plant of it in his garden, which he received from

[1] Mill. dict. & ſp. [2] Woodw. MS.

his very good friend Master Garret, an apothecary. It was not then known to grow wild in England.

Johnson adds, that it was reported to grow in the north parts of this kingdom; and that he saw it in flower with Mr. Tradescant. Its old name in English was *Our Ladies shoe* or *slipper*, from the latin, *Calceolus D. Mariæ*, or *Marianus*. It is the same in the other European languages. In German, *Marienschuh*. In French, *Sabot de la Vierge*, or *Soulier de Notre-Dame*. In Italian, *Pantoffola* or *scarpa della Madonna*, &c.]

It flowers the end of may, and the ſtalks decay to the root in autumn, new ones riſing the following ſpring.

β. The ſtalks riſe near a foot and half high; it has longer and ſmoother leaves than the European. The two ſide petals of the flower are long, narrow, terminate in acute points, and the ſides are waving. The nectarium is oblong and narrower, yellow, ſpotted with brownish red. Native of Virginia, and other parts of North America.

γ. This riſes a foot and half high. The leaves are of an oblong oval form, and deeply veined. The flower is large, of a reddiſh brown colour, marked with a few purple veins. It flowers the end of may.

Native of America, where it is called Moccaſin flower. [These are thought to be diſtinct ſpecies. This is probably the ſame with our fourth; but *bulboſum* of Miller does not correſpond with our ſecond.

2. Root a bulb, throwing out a few thick fibres from its lower part, and inveſted with a ſemi-tranſparent, acute, erect membrane, riſing far above its top. Leaf radical, ſolitary, petioled, oval, ſomewhat pointed, entire, ribbed, ſmooth, dark green, ſpotted with brown, very like the Dog's-tooth Violet. Stalk three inches high, erect, round, one-flowered, inveſted with two tubular, membranous ſheaths. Bractæ ſolitary, not far from the flower, linear-lanceolate, acute, purpliſh. Flower a little inclined. Petals five, all pointing upwards, ſpreading, lanceolate, acute, three-nerved, purple, three on the outſide of the other two. Lower lip of the nectary as long as the petals, very large, pendulous, ſtreaked with purple, having a prominent cloven point in the fore-part beneath, gaping above, with a ſpreading, reflex, dependent margin, and bearded in the orifice with a little tuft of yellow hairs; the upper lip ſhorter than the petals, erect, broad-oval, entire, almoſt of the ſame ſubſtance and colour with the petals[5].

Native of Lapland, Ruſſia, Siberia, and Nova Scotia.

3. Stem round, erect, villoſe, a foot high. Leaves in the middle of the ſtem two, embracing, acute, ſinuate-waved, ſmooth, a hand broad. Below the flower a ſeſſile, ſolitary, oblong, acute, entire leaflet, ſcarcely an inch in length. Flower terminating, ſolitary, the ſize of that of the common ſpecies. Native of Japan, flowering in april and may[6].

4. This ſpecies derives its name from the whiteneſs of its petals. The large nectary is tinged with purple. It is the moſt magnificent of the genus; whence Mr. Saliſbury has called it *ſpectabilis*: indeed there are few flowers which to ſuch ſingularity of ſtructure add ſuch elegance and beauty. It grows ſpontaneouſly in ſarious parts of North America, chiefly in the woods. In the catalogue of the royal garden at Kew, it is ſaid to have been introduced there by Mr. William Young, about the year 1770, but it was known to Mr. Miller, and cultivated by him at Chelſea, long before that period[7]; if it be his *bulboſum*.

5. Has rarely more than two radical leaves, a very ſhort flowering ſtem compared with the others, a large nectary in proportion to the ſize of the plant, divided on its upper part, through its whole length, ſo as to deſtroy in a great degree that ſhoe or ſlipper-like form from which this genus has taken its name. It flowers with us in may[8].—Native of North America. Introduced in 1786, by William Hamilton, Eſq.[9].

PROPAGATION AND CULTURE.

All theſe ſorts are with ſome difficulty preſerved in gardens; they muſt be planted in a loamy ſoil, and in a ſituation where they may have the morning ſun only. They muſt be procured from the places where they naturally grow, for they cannot be propagated in gardens. The roots ſhould be ſeldom removed, for tranſplanting them prevents their flowering.

[Our Engliſh ſort ſucceeds very well in a pot, ſet under a hedge, where it has the morning ſun only, and will laſt thus many years. The roots will ſpread ſo as to fill the pot, and the plant may be propagated by parting the roots, but it muſt be done with caution. The American ſorts require a little ſhelter in ſevere weather.

The gardeners (ſays Dr. Stokes) might make the botaniſts amends for rooting out theſe rare wild plants in their natural places of growth, and at the ſame time enrich themſelves, if they would prove by experiment that one at leaſt of the Orchis tribe may be raiſed from ſeed[1].

SPECIES.

1. Cyrilla pulchella.

L'Herit. ſt. nov. 6. 147. *t.* 71. *Brown. jam.* 271. *t.* 30. *f.* 1. (Achimenes).

DESCRIPTION, &c.

This is a handſome plant. Root branched, fibroſe, ſtoloniferous. The young ſhoots reſemble ament or catkins, are cylindric, and cloſely imbricate, with ovate pubeſcent ſcales, thickened at the baſe, emarginate and red. Stems ſeveral, almoſt upright, branched, round, extremely villoſe, duſky purple, herbaceous: branches ternate, ſpreading. Stem-leaves in threes, on the branches uſually oppoſite,

[5] Smith ſpicil. [6] Thunberg. [7] Curt. magaz.

[8] Curt. magaz. [9] Hort. kew. [1] With. Arr.

petioled, ovate or ovate-lanceolate, sharp at both ends, loosely serrate, entire at the base, with nerves prominent below, grooved above, villose on both sides, bright green, beneath paler, and very frequently blood-red. Petioles round on one side, on the other flattish and slightly channelled, one third only of the length of the leaves. Flowers resembling those of *Ruellia*, axillary, solitary, peduncled, inclined, red. Peduncles spreading very much, round, villose, red, twice the length of the petioles. Calyx villose, ending in a turbinate germ, red at the base. Tube of the corolla pubescent: throat tricallous at bottom; with oblong tubercles, hollowed outwards, each opposite to each segment. Besides the four fertile filaments, there is a fifth superior to and shorter than the others, which has no anther. This plant is distinguished from *Gesneria* by its funnel-form corolla, with a cylindric straight tube, and a flat almost equal border.

Native of Jamaica[a]. Browne observed it near Hope-river, in the lower mountains of Liguanea. It flowers here at the end of summer and the beginning of autumn.

PROPAGATION AND CULTURE.

It must be kept in the bark stove, and may be propagated by suckers. It never produces seed here. It deserves to be cultivated in the West-Indies for its beauty and elegance. There it thrives best in a cool moist gravel, mixed with rich mould[b].

Cyrilla racemiflora. See *Itea*.

CYRTANDRA. See *Besleria*.

CYRTANTHUS. (*From* κυρτος *bent, and* ανθος *a flower.*)

Ait. hort. kew. 3. 510.

Clafs. 6. 1. Hexandria Monogynia.

Nat. order of *Spathaceæ. Narciſſi.* Juſſ.

GENERIC CHARACTER.

Cal. none.

Cor. one-petalled, club-ſhaped, bent, ſix-cleft at top: ſegments ovate-oblong; the three inner blunt, the three outer terminating in a little horn.

Stam. *Filaments* ſix, faſtened to the tube, filiform-ſubulate, a little ſhorter than the corolla. *Anthers* oblong, erect.

Pist. *Germ* inferior, ovate, obtuſely three-cornered. *Style* filiform, the length of the *corolla*. *Stigma* trifid.

ESSENTIAL CHARACTER.

Cor. tubular, club-ſhaped, crooked, ſix-cleft; ſegments ovate-oblong. *Filam.* inſerted into the tube, converging at top.

DESCRIPTION, *&c.*

A paraſitical plant growing at the roots of the Ciſtus. Leaves ſeſſile, cloſely imbricate. Flowers terminating, heaped[a].

Below the flower are two oppoſite ſcales, becoming purple by age. The colour of the flower itſelf is dirty yellow. The number of anthers, and the diviſions of the ſtigma vary: the number of the anthers is double the diviſions of the ſtigma. Annual[b].

Native of the county of Nice, Spain, Portugal and Barbary.]

CYTISO-GENISTA. See *Spartium*.

CYTISUS. (*Name of Hippocrates, Theophraſtus and Dioſcorides. Said by Pliny to have been firſt found in the iſle of Cythnus; whence it is ſuppoſed to have derived its name.*)

Lin. gen. n. 877. *Reich.* 951. *Schreb.* 1191. *Tourn.* 416. *Juſſ.* 358.

Claſſ. 17. 4. Diadelphia Decandria.

Nat. order of *Papilionaceæ*, or *Leguminoſæ*.

GENERIC CHARACTER.

Cal. *Perianth* one leafed, bell-form, ſhort, obtuſe at the baſe: *mouth* two-lipped: *upper* lip two-cleft, acuminate: *lower* three-toothed.

Cor. Papilionaceous.

Standard ovate, riſing upwards, ſides reflex.

Wings the length of the ſtandard, ſtraight, obtuſe.

Keel ſomewhat bellied, acuminate.

Stam. *Filaments* diadelphous, (ſingle and nine-cleft) riſing upwards. *Anthers* ſimple.

Pist. *Germ* oblong. *Style* ſimple, riſing upwards. *Stigma* obtuſe.

Per. *Legume* oblong, obtuſe, attenuated at the baſe, ſtiff.

Seeds a few, kidney-form, compreſſed.

Obs. C. Cajan *has the wings of the corolla flat horizontally, and an obtuſe keel.*

C. ſupinus *has a tubular calyx, which is bellied, and two-lipped.*

ESSENTIAL CHARACTER.

Cal. two-lipped: upper lip two-cleft, lower three-toothed. *Legume* attenuated at the baſe.

[a] Juſſieu. [b] Allioni.

SPECIES.

SPECIES.

Flowers peduncled ſolitary; leaves ſmooth; ſtems decumbent, becoming ſhrubby; legumes ſickled above.

13. Cytisus glaber.
Lin. ſyſt. 667. *ſuppl.* 328.—ſiliqua anguſta. *Baub. hiſt.* 1, 2. 373. *f.* 1.
Flowers ſolitary lateral ſubſeſſile pendulous; leaves ternate.]

14. Cytisus græcus.
Lin. ſpec. 1043. *Reich.* 3. 484.
Leaves ſimple lanceolate-linear, branches angular.

15. Cytisus tener.
Lin. ſyſt. 667. *Jacqu. collect.* 1. 40. *icon. rar. t.* 147.
Spartium virgatum. *Ait. hort. kew.* 3. 11.
Leaves ſimple lanceolate; branches round.

16. Cytisus foliolosus. *Leafy Cytiſus.*
Ait. hort. kew. 3. 49.
Racemes terminating erect; calyxes villoſe, ſegments ſickle-ſhaped; leaflets obovate-oblong.

17. Cytisus divaricatus. *Clammy Cytiſus.*
L'Herit. ſtirp. nov. 1. 91. *icon. Ait. hort. kew.* 3. 50.
Spartium complicatum. *Lin. ſpec.* 996.
Racemes terminating erect; calyxes and legumes ramentaceous-viſcid; leaflets oblong.

18. Cytisus biflorus. *Smooth Cytiſus.*
L'Herit. ſtirp. nov. 1. 92. *icon. Ait. hort. kew.* 3. 52.
Peduncles generally in pairs lateral; calyxes oblong villoſe two-lipped, upper lip bifid; leaflets oblong-elliptic.

DESCRIPTIONS, *&c.*

All the ſpecies of Cytiſus are ſhrubs without ſpines, moſt of them very fit for ornamental plantations. They are chiefly hardy; the leaves ternate; the flowers, except in the twelfth, yellow, and growing in bunches.

1. The common height of the Laburnum is from eight to fifteen feet, but in good ground and when planted thick it will run up much higher. Leaves ternate, on long petioles, commonly three together from one point: leaflets quite entire, ſmooth and pale green on the upper ſurface, glaucous and covered with ſhort appreſſed hairs on the lower, which has a ſtrong prominent nerve or midrib. The flowers come out from the ſame ſhort ſpurs with the leaves in naked, handſome, villoſe racemes, a ſpan in length: and beyond theſe young ſhoots are produced, which are white, and bear the ternate leaves ſingly. Each flower hangs from a long pedicel. Calyx yellowiſh, ſmall, two-lipped: the upper lip cloven, the lower having three minute teeth. Corolla

pale yellow; ſtandard broad, emarginate with duſky ſpots and dots within at the baſe; wings longer than the keel, hooked; keel in two parts; ſtamini-ferous ſheath in one piece, the two upper filaments ſtanding croſſwiſe: germ ſmooth. Legume from an inch to near two inches in length, covered with white appreſſed hairs, containing from one or two to ſix or ſeven ripe ſeeds, which are black and ſhining; ſeveral at one or both ends are frequently abortive[a].

There are two varieties of Laburnum, which Mr. Miller regards as diſtinct ſorts.] The firſt broad-leaved, which was formerly more common in the Engliſh gardens than at preſent; and the ſecond, the narrow-leaved, which having much longer ſpikes of flowers makes a finer appearance, and has in a manner diſcarded the other from ornamental plantations: the firſt however grows to be the largeſt tree, and the wood of it is very hard, of a fine colour, and will poliſh very well; it approaches near to green Ebony, and is called by the French Ebony of the Alps, and is there uſed for many kinds of furniture; but in England there are few of theſe trees which have been ſuffered to ſtand long enough to arrive to any conſiderable ſize, for as they have been only conſidered as ornamental, the frequent alterations which moſt of the gardens in England have undergone, have occaſioned their being rooted out wherever they were growing; but in ſome of the old gardens in Scotland, where they have been permitted to ſtand, there are large trees of this kind, which are fit to cut down for the uſe of the timber. I have ſeen two old trees of it in gardens, which were more than a yard in girt, at ſix feet from the ground, and theſe had been broken and abuſed, otherwiſe might have been much larger: they grow very faſt, and are extremely hardy, and therefore may be well worth propagating upon poor ſhallow ſoils, and in expoſed ſituations. His Grace the Duke of Queenſberry ſowed a great quantity of the ſeeds of this tree, upon the ſide of the downs, at his ſeat near Amelbury, in Wiltſhire, where the ſituation was very much expoſed, and the ſoil ſo ſhallow, that few trees would grow there: yet in this place the young trees were twelve feet high in four years growth, and became a ſhelter to the other plantations, for which purpoſe they were deſigned; but the hares and rabbits being great enemies to theſe trees, by barking them in winter, they ſhould be fenced from theſe animals.

[Hence it is ſuggeſted by Mr. Boutcher that the Laburnum is very proper to ſow in plantations infeſted with hares and rabbits, who will touch no other plant ſo long as a twig of Laburnum remains. Though eaten to the ground in winter it will ſpring again the next ſeaſon, and thus conſtantly ſupply theſe noxious animals: ſo that by expending five ſhillings in Laburnum ſeed a whole plantation may be ſecured.

But the Laburnum is not only uſeful in preſerving other more valuable trees. The wood is of great ſtrength, and is much uſed for pegs, wedges, muſical inſtruments, handles of knives, and a variety of furniture. Mr. Boutcher mentions, that he had ſeen a large table and a dozen chairs made of it, which judges of elegant furniture thought the fineſt they had ever ſeen. Pliny ſays its wood is the hardeſt of any next to Ebony. Matthiolus ſpeaks of its being uſed for making the beſt bows. It chars remarkably well; and if planted thick to run up tall, it would make durable hop-poles.] For this purpoſe it might be planted in large clumps in parks, where it would be alſo very ornamental; the branches being generally loaded with long ſtrings of flowers, hanging down from every part of them, in the month of may. [Haller obſerves, that it is very bitter, and that the ſeed both purges and vomits violently. He alſo remarks, that the Latin name *Laburnum* was evidently formed from the alpine name *L'Aubours*. Formerly it was called in Engliſh *Bean-Trefoil* and *Peaſcod-tree*, but the Latin name has prevailed over theſe. In German it is *Bohnenbaum*, and in French *Cytiſe des Alpes*, *Aubours*, and *Faux Ebenier*.

It is a native of Switzerland, Auſtria, Provence, *&c.* and was cultivated here by Gerarde in 1596[b]. Tradeſcant had both varieties in his garden[c].]

2. This ſhrub ſeldom riſes more than three or four feet high in England; it naturally puts out many lateral branches near the ground, which ſpread out on every ſide, ſo as to form a low ſhrubby buſh, which is with difficulty raiſed to a ſtem: the branches are very ſlender, and their ends are frequently killed in ſevere winters. The leaves grow by threes, are equal in ſize, and of a dark green colour. The branches grow erect, and are terminated by bunches of yellow flowers, about four or five inches in length, and making a fine appearance.

[The branches, calyx and legume, as well as the under ſurface of the leaves, are covered with a fine ſilvery pile[d]: the end leaflet is larger than the ſide ones[e]. In its native place of growth it is found from a foot and half to the height of a man, with erect, round, ſmooth, pliant ſtems[f]. The flowers are pendulous on ſhort peduncles, and have an agreeable odour. The upper lip of the calyx is entire; the three teeth of the lower are very ſmall. Standard of the corolla roundiſh, blunt, reflex; keel very large and wide; wings a little ſhorter: the whole flower has a ſhort and broad appearance[g].

Native of Sileſia, Auſtria, Hungary and Italy.—Cultivated in 1731, by Mr. Miller[h], who ſays, that it was formerly in ſome of the curious gardens here, but had been long loſt, till he procured the ſeeds, which ſucceeded in the Cheſſea garden. It flowers in july, after moſt of the other ſorts are paſt.

[3. This is a very handſome ſhrub, ſcarcely growing to two feet in height. The leaves have from three to nine, but uſually ſix or ſeven pairs of leaflets, terminated by an odd one; they are ſmooth above, ſilvery beneath, and moſtly orbiculate. The flowers are large, and of a deep yellow colour[i]; in axillary and terminating racemes, erect, on peduncles much longer than the leaves, about ten in number, generally oppoſite or nearly ſo in pairs, with a ſmall acuminate bracte to each pedicel. Calyx and pedicels lanuginoſe, and having reddiſh glutinoſe glands ſcattered over them. Calyx deeply five-cleft; the ſegments ſubulate, equal, the loweſt narrower than the reſt. Legumes cylindric, ſwelling at the end, ſomewhat toroſe, hirſute with glandular hairs. Seeds large, gray, teſtaceous-variegated[k].

Native of Siberia, in the deſerts between the Tanais and the Wolga: obſerved there by Pallas[l]. Introduced here in 1786, by William Pitcairn, M. D.[m]]

4. This riſes with a woody ſtalk, putting out many branches, covered with a browniſh bark. Leaflets obovate, ternate, on very ſhort petioles. Flowers in cloſe ſhort terminating racemes, of a bright yellow colour. Legumes ſhort and broad. This ſhrub riſes to the height of ſeven or eight feet, and becomes very buſhy. [The leaves are on long petioles, but on the flowering-branches ſeſſile. Filaments all connate at bottom. Legumes blackiſh[n]. This ſhrub is eaſily known by its ſmoothneſs, the uprightneſs of the ſtalks and racemes, and particularly by the triple bracte immediately below the flower.

Native of the South of Europe. Cultivated here in 1713[o]. Mr. Miller ſays it has been long cultivated in the nurſery gardens as an ornamental ſhrub, by the title of Cytiſus ſecundus Cluſii. [If it be C. vulgatior of Parkinſon, it was common among us in 1629. According to Johnſon, it grew in the garden of Mr. John Tradeſcant.

Ruminating animals greedily devour the leaves and young branches of this ſort, whilſt the goat only touches the Laburnum[p].]

[a] Haller. Scopoli, Jacquin.

[b] Hort. kew. [c] Johnſon in Ger. emac. [d] Haller.
[e] Linn. ſyſt. [f] Jacquin. [g] Haller. [h] Hort. kew.
[i] Linn. ſuppl. [k] Pallas. [l] Linn. ſuppl. [m] Hort. kew.
[n] Linn. ſyſt. and Crantz. [o] Hort. kew. [p] Villars.

5. This riſes with a weak ſhrubby ſtalk eight or ten feet high, ſending out many ſide branches, which grow erect. The flowers come out from the ſide of the branches, ſingle or in cluſters; they are of a deep yellow colour, and about the ſize of thoſe of the common Laburnum. Legumes hairy, about three inches long, ſickle-ſhaped, ending in a long ſharp point, ſwelling where each ſeed is lodged. Seeds roundiſh, a little inclined to kidney-ſhape. [The leaves are very ſoft, in ſome views white. Calyx ſubpubeſcent. Standard of the corolla erect, wings horizontally flat, keel blunt. Stamens truly diadelphous. Legume intercepted by obliquely tranſverſe ſtreaks[1].

The Pigeon Pea is frequently planted in the Weſt India iſlands, chiefly in rows as a fence to the ſugar plantations, and will thrive on barren land. The ſeed is much eaten by poor people and negroes, and is eſteemed a wholeſome pulſe; in the iſland of Martinico even the better ſort of people hold it in eſtimation, and prefer it to the European Pea. The chief uſe of it in Jamaica is for feeding Pigeons, whence its name. The branches with the ripe ſeed and leaves are given to feed hogs, horſes, and other cattle, which grow very fat on them[2].

Native of both Indies and Africa, whence they are ſuppoſed to have been originally brought to the Weſt Indies, where they are called *Angola Peas* and *Pois d'Angola*.—It was cultivated in 1694, by the Dutcheſs of Beaufort[3]; and by Doody in 1687[4].]

6. This has a ſoft ſhrubby ſtalk, dividing into many branches, which grow erect, and frequently riſe to the height of eight or ten feet; the ſtalks, branches, and leaves are very hairy; the leaves are ternate, ovate, and placed cloſely on the branches; the flowers come out from the ſide of the ſtalk, in ſhort racemes, they are of a pale yellow, appear in june, and are ſucceeded by long, narrow, hairy legumes, which ripen in ſeptember.

[The branches are decumbent, the calyxes extremely hirſute, the ſtamens all connate at bottom, the legumes black, the ſeeds ovate, ſix, ſeven or eight, pedicelled, with two ſmall bractes embracing the pedicel[5].

Native of the South of Europe and Siberia. Cultivated in 1739 by Mr. Miller,] who ſays that it is common in the nurſery gardens near London, under the name of Evergreen Cytiſus of Naples.

[7. Stem and petioles pubeſcent. Leaves ſmoothiſh Calyx tubular, bellying, pubeſcent[6]. It differs from the preceding in having moſt of the flowers terminating, and in a genuine head; the leaves more obtuſe, and hairy on both ſides; the ſtems ſcarcely ever a cubit in height, and extremely hirſute[7].

Native of Auſtria, Carniola, and Sileſia. Introduced in 1774, by Joſ. Nich. de Jacquin, M. D.[8]]

8. This has a ſhrubby ſtalk, which riſes near four feet high, dividing into many branches, which when young are covered with a green bark; the flowers are produced in cloſe heads at the ends of the branches, having a cluſter of leaves under them; they are of a bright yellow colour, appear in the beginning of may, and are ſometimes ſucceeded by ſhort woolly legumes, containing three or four ſmall ſeeds.

[This reſembles *C. ſupinus*, but the ſtems are erect, very branching and panicled. The leaflets are lanceolate not ovate[9], ſmoothiſh but covered on both ſides with a ſhining aſh-coloured ſhort pile, quite entire, terminated by a ſhining toothlet; petiole long, hoary, hairy. Flowers in each umbel from five to ten, ſupported by one or two toothletted bractes, and without any ſide flowers. Calyx yellowiſh, woolly. Standard of the corolla villoſe at the back, emarginate, wide, with the edges fringed as it were and curled; wings longer than the keel, with waving edges; keel cloven, ſpreading, villoſe. Filaments all connate. Legumes hirſute, erect[10].

Native of Auſtria, Hungary, Sileſia, Italy, and Siberia. It was cultivated in 1756, by Mr. Miller[11]; who ſays, that the ſeeds were ſent to the Imperial garden at Peterſburg, and thence by Profeſſor Amman to England.

9. [The ſtems of this are almoſt wholly procumbent, round, duſky, little divided: the ends are cloſely beſet with leaves and flowers, which come out together from ſpreading buds, formed of a few ſubovate ſimple bractes; the longer ſtems are frequently decorated with flowers for a foot in length; two flowers uſually proceed from each bud, but ſometimes only one, and rarely three or more, on ſhort peduncles. The younger branches, the petioles, peduncles, and leaves, eſpecially underneath, are covered with ſoft whitiſh hairs, which are frequently ſhort and ſcarcely viſible. Calyx pale and hirſute; lower lip quite entire, upper ſhortly bifid. Standard of the corolla roundiſh, wide, emarginate, longer than the wings. All the filaments connate. Flowers erect, deep yellow, but before they decay becoming reddiſh. Legume oblong, much compreſſed, brown, ſtraight, hairy. Seeds ſeveral, ſhining, brown. In the garden it becomes more pubeſcent, and by age more ſhrubby, branched and diffuſed, riſing to four feet in height, with long recurved branches loaded with flowers[12].

Native of the South of Europe and Siberia. Cultivated in 1759, by Mr. Miller[13].

10. This reſembles the next ſpecies. The ſtems, but eſpecially the ſmall branches are almoſt tomentoſe. Leaves alternate, petioled. Peduncles axillary, (four to eight) equal, one-flowered, a little longer than the petiole, filiform, villoſe, with two oppoſite filiform bractes near the flower. Corollas large, white. When the flowering is paſt, a branch grows out in the centre of the peduncles.

Found in the mountain woods of Teneriffe by Francis Maſſon[14]. Introduced in 1779. It flowers in april and may[15].]

11. This has herbaceous ſtalks. The flowers are produced either ſingle, or two, three or more together, at the ends of the branches.

[It is a hoary ſhining plant; the branches towards the root become ſhrubby, but above they are herbaceous. Bractes two or three, growing to the baſe of the calyx. The ſegments of the calyx are longer than in the other ſpecies. Legumes hirſute[16].

Scopoli obſerves, that the ſtems are ſlender and branched, the flowers ſolitary, the calyx villoſe, the petals yellow, the ſtandard villoſe, the wings ſmooth, and the germ very hairy.

Native of the South of France and Iſtria. Cultivated in 1739, by Mr. Miller[17].

12. This is ſuffruticoſe. Stems the thickneſs of a gooſe quill, naked, ſmooth, browniſh, pliant, proſtrate; from theſe ſpring ſlender, ſoft, aſcending, branched twigs, at firſt ſlightly pubeſcent, but afterwards ſmooth. Leaves ſcattered, alternate, petioled; leaflets ſeſſile, ovate, ſharpiſh, dark green, quite entire. Flowers axillary, ſolitary, erect on a ſhort pedicel. Calyx tinged with purple; upper lip ſhorter, two-toothed; lower a little longer, ovate, acute, entire. Corolla large, bright red: ſtandard obcordate, broad, villoſe-ciliate on the ſides at bottom; wings oblong-oval, entire, converging; keel blunt, both that and the wings villoſe-ciliate at the baſe. Filaments all connate. Anthers orange-coloured. Legume much narrower at the baſe, ſubpeduncled, linear, compreſſed, ſickle-ſhaped, black when ripe, and commonly ſmooth.

Firſt found by Profeſſor Jacquin in Carniola, in 1761; flowering in april and may[18].

13. Leaves petioled; leaflets equal, lanceolate-elliptic, whitiſh about the edge, ſmall, acute, ſcarce perceptibly hairy underneath. Stipules none. Peduncles ſhorter than the flowers. Calyx oblong,

[1] Linn. ſyſt. [2] Sloane and Jacqu. obſ. [3] Hort. kew. [4] Ray. [5] Linn. Crantz. Krock. [6] Linn. ſyſt. [7] Krock. and Scop. [8] Hort. kew. [9] Linn. ſpec. [10] Krocker. [11] Hort. kew. ſomewhat bellying, trifid. Corolla yellow, rather large.

Native of Auſtria [1].]

14. This riſes with a woody ſtalk ſix or ſeven feet high, ſending out many angular lateral branches. The flowers are produced in ſhort bunches from the ſides of the branches; they are ſmall, yellow, and appear in july and auguſt, but are not ſucceeded by ſeeds in England. It grows naturally in the iſlands of the Archipelago.

[15. This is an erect ſhrub, branching very much, three feet high, with a trunk the thickneſs of a finger, round and upright. Leaves quite entire, ſubpetioled, pale beneath, ſomewhat villoſe on both ſides, ſcarcely half an inch in length. Flowers few in terminating racemes, on ſhort pedicels, ſmelling ſweet. Legumes hirſute. Seed few [2].

Found in the iſland of Madeira by Maſſon. Introduced here in 1777 [3].

16. Found in the Canary iſlands by Maſſon. Introduced in 1779. It flowers in july and auguſt [4].

17. Leaves ternate, with ovate-oblong leaflets, (Linneus ſays, lanceolate, never unfolding,) on very ſhort petiolets. Racemes ſimple. Flowers pedunculed, ſolitary, ſupported by one or two ſubulate bractes. Before the corolla opens the whole is tawny, but when open, the ſtandard about the middle only is of that colour; the reſt is then yellow: the calyx is alſo tawny. Linneus obſerves, that the ſtamens have large and ſmall anthers alternate.

Native of the South of France, Spain, and Madeira. Cultivated in 1763, by Mr. James Gordon. It flowers in july and auguſt [5].

18. Cultivated in 1760, by Mr. James Gordon. It flowers in may and june [6].]

PROPAGATION AND CULTURE.

1. The Laburnum is eaſily propagated by ſeeds, which the trees produce in great plenty. If theſe are ſown upon a common bed in march, the plants will appear by the middle or end of april, and will require no other care but to be kept clean from weeds during the following ſummer; and if the plants are too cloſe together, they may be tranſplanted the autumn following, either into a nurſery, where they may grow a year or two to get ſtrength, or into the places where they are deſigned to remain: where people would cultivate them for their wood, it will be the beſt way to ſow the ſeeds upon the ſpot where they are intended to grow, becauſe theſe trees ſend out long, thick, fleſhy roots to a great diſtance, which will penetrate gravel or rocks; and if theſe roots are cut or broken, it greatly retards their growth: therefore when they are not ſown upon the intended ſpot, they ſhould be tranſplanted thither young, otherwiſe they will not grow to near the ſize; though where they are only deſigned for ornament, the removing the plants twice will ſtop their growth, and cauſe them to be more productive of flowers; but all trees intended for timber, are much better ſown on the ground where they are deſigned to ſtand, than if they are tranſplanted.

If the ſeeds of theſe trees are permitted to ſcatter in winter, the plants will riſe in great plenty the following ſpring, ſo that a few trees will ſoon ſupply any perſon with a ſufficient number of the plants.

There is a variety with variegated leaves, which can only be continued by cuttings or layers: the cuttings ſhould be planted in autumn, when the leaves begin to fall; and the plants muſt have a poor ſoil, for in good ground they are apt to become plain.

The Laburnum will thrive upon many different ſoils, and in ſuch ſituations as few other trees will make any progreſs. [It will grow in a poor hungry ſoil, but where there is any depth it will make great progreſs.

[1] Linn. ſuppl. [2] Jacquin. [3] Hort. kew. [4] Hort. kew. [5] Ibid. [6] Ibid.

Mr. Boutcher recommends the ſeedling plants to be removed to the nurſery in february or march, ſhortening their roots, which are not injured by cutting them freely when young; and planting them two feet and a half diſtant from row to row, and a foot aſunder in the rows, there to remain two ſeaſons. Hence they may be removed either in october or february, ſtill reducing the downright roots, and ſmoothing the extremities of the ſpreading ones; pruning off all ill-placed ſide branches, but leaving ſome of the ſmalleſt at proper diſtances. The rows may now be five feet apart; the plants two feet aſunder; and here they may remain three or four years.

Theſe directions are more adapted to raiſing trees for ornamental plantations than for uſe.

If they are deſigned for poles, they ſhould be kept to ſmaller diſtances. The autumn after they are ſowed, they may be pricked out three or four inches apart, and the following ſpring to the diſtance of nine inches or a foot, there to remain three or four years, according to their growth, when they may be removed, being fourteen or ſixteen feet high, to the places where they are deſigned to remain, only ſhortening the lateral roots, and juſt topping the tap root. Thus they will run up with few lateral branches and ſmall heads, to the height of from twenty to forty feet.]

2, 3, 7, 9, 11, 12, 13, 17. Theſe may be propagated by ſeeds, which ſhould be ſown upon a bed of light earth in march, covering them about one third of an inch with fine ſcreened mould; in the beginning of may the plants will appear, when they muſt be carefully weeded, and during the following ſummer they muſt conſtantly be kept clean, which is all the culture they require till autumn, when it will be very proper to arch the bed over with hoops, that in froſty weather the plants may be covered with mats, to prevent their tender ſhoots from being killed; for as theſe young plants are apt to continue growing later in the autumn than thoſe which are become woody, they are much more ſuſceptible of cold; therefore where there is not ſome care taken to cover them, if the winter ſhould prove ſevere, many of them may be entirely deſtroyed, and the others killed to the ground. The ſpring following, after the danger of hard froſt is over, the plants ſhould be carefully taken up, and planted out at the diſtance of one foot, row from row, and ſix inches aſunder in the rows; this ſhould be in a ſheltered ſituation, and as theſe plants do not ſhoot till late in the ſpring, they need not be tranſplanted before the end of march, or the beginning of april; and if the ſeaſon ſhould then prove warm and dry, it will be proper to give the plants ſome water to ſettle the earth to their roots; and if the drought continue, and the waterings are three times repeated at a week's interval from each, it will be of ſervice to the plants. After they have taken new root, they will require no farther care, but to keep them conſtantly clean from weeds; in this nurſery the plants may remain two years, in which time they will have acquired ſtrength enough to be tranſplanted where they are to remain.

4. This being very hardy, will thrive in any ſituation, and almoſt on any ſoil that is not too wet. It is propagated by ſeeds, which may be ſown upon a common bed of light earth in the ſpring; in autumn the plants may be removed into a nurſery in rows, one foot apart, and at ſix inches diſtance in the rows, where they may remain two years to acquire ſtrength, and ſhould then be removed to the places where they are deſigned to grow.

5. This plant grows only in hot countries, and cannot be preſerved in England, but in the bark-ſtove. It riſes eaſily from ſeeds in a hot-bed, and will grow three or four feet high the firſt year, provided it have a proper heat; and the ſecond year the plants will produce flowers and ſeeds. They muſt be treated in the ſame manner as other tender plants from the ſame countries; ſhould have little water in winter; and in ſummer ſhould have a

large

large ſhare of air admitted to them in warm weather.

6. The Evergreen Cytiſus may be propagated in the ſame manner as has been directed for the ſecond ſort; but as it is ſometimes killed in ſevere froſts, it ſhould be planted only on a dry ſoil, and in a warm ſituation: it is alſo very difficult to remove, when grown to any ſize, becauſe it ſhoots long roots deep into the ground, and when theſe are broken or cut, the plant ſeldom ſurvives it.

8. This alſo is propagated by ſeeds, which ſhould be ſown early in april, on a border of ſtrong ground expoſed to the eaſt; for if they are ſown where they have full ſun, the plants will not thrive. This requires a cold ſituation and a ſtrong ſoil.

14. This is propagated by cuttings, which if planted on a bed of light earth the beginning of july, and cloſely covered with a bell or hand-glaſs ſhaded from the ſun in the middle of the day, will put out roots by the middle or end of ſeptember; when they ſhould be carefully taken up, planting each in a ſeparate ſmall pot, carefully watering and ſhading them until they have taken new root, after which they may be expoſed in a ſheltered ſituation until the end of october, when they muſt be removed into ſhelter, for they are too tender to live in the open air in England.

[10, 15, 16, 17. Will not bear the open air of our climate, but require the protection of a green-houſe or dry ſtove.

7. Dactylis patens. *Spreading Cock's-foot Graſs.*

Ait. hort. kew. 104.

Spikes ſcattered, turned one way, few; flowers cloſely imbricate; culm decumbent, leaves ſpreading very much.

DESCRIPTIONS, *&c.*

1. Culm two feet high, reedy. Leaves on the culm ſix, broad, longer than the culm, very glolly, ſcabrous about the edge, bent in, more glaucous on their inner ſurface. Spikes ſix or more, diverging, chaffy: floſcules ſcabrous behind: calyxes one-flowered, ſcabrous on the keel, mucronate, longer than the floſcule ſeſſile, turned one way: piſtils villoſe, very long.—Native of Virginia and Canada. Perennial [a].

2. *Root* perennial. *Culms* from two to three feet high, ancipital, naked and rugged at top, having four or five ſmooth, purpliſh knots or joints, and three leaves, with ancipital villoſe or rugged ſheaths, ſharply keeled. *Leaves* ſix inches or more in length, and three or four lines broad, ſpreading, ſomewhat glaucous, very rugged on both ſides with extremely minute ſpinules. Ligule white, oblong, obtuſe, cloven. *Panicle* cloſe, often coloured: peduncles ſolitary, alternate, angular, ſtiff, rugged, with a callous tumour at the baſe, twice and thrice cloven; the loweſt (ſometimes two) more remote, longer, ſpreading, at length becoming horizontal and even ſomewhat reflex. Spikelets all turned the ſame way, ſubſeſſile, twin-glomerate, oblong, very obtuſe, having two, three, and ſometimes four flowers, preſſed cloſe, and during floreſcence diverging. Calyx pubeſcent, frequently ciliate, rugged, having a ſhort awn; inner valve twice as large as the outer, awned, equal to the florets if there be only two, but ſhorter if there be more. Florets rugged, edged with white, obtuſe, with a ſhort awn at the end, in the laſt floret this is very ſhort, and ſometimes there is none: inner valve ſcarcely ſhorter than the outer, with the end ſharply cloven: nectaries two lanceolate-acuminate: filaments twice the length of the corolla; anthers yellow or purple, and afterwards white. Seed dropping [b].

There is ſome difference of opinion reſpecting the genus of this graſs. Scopoli at firſt made it a *Poa*, but afterwards, following Haller, he ranged it among the *Bromi*. He ſays it is not a *Poa*, becauſe it has one awned petal; not a *Cynoſurus*, becauſe the calyx is many-flowered, and it has no bractes; not a *Dactylis*, becauſe the calyx is very acute.

[a] Linn. ſpec. [b] Leers.

Pollich mentions a viviparous variety; and Mr. Woodward has obſerved it to be ſo in rainy ſeaſons. This is uſual in other graſſes on lofty ſituations, where they are frequently drenched by the clouds.

No graſs is more common than this; from its flouriſhing particularly under the ſhade of trees, whence it has been called *Orchard-graſs*. It flowers from june to auguſt.

It is a rough coarſe graſs, and hence has the names of *Rough-graſs* and *Hard-graſs*, but it is extremely hardy and productive; Mr. Curtis adds that it is rather early. Its flouriſhing under the drip of trees may be a recommendation, but the head is ſo large that in heavy rains it is apt to be laid. It ſhould always be cut whilſt young and tender either for hay or fodder.

3. Root filiform, creeping with long white fibres. Culms a palm high, aſcending, very ſimple, even, with one joint. Root-leaves involute, filiform, even, the length of the culm; ſtem-leaf one, even, the length of the head; ſheath ſomewhat bellying. Head terminating, ovate, with many ſeſſile flowers. Glume of the calyx three-flowered, compreſſed, mucronate, the length of the corolla, having ſcattered hairs on the back under the tip. Outer glume of the corolla ovate, ſtriated, bearded below with white hairs.

Native of the Cape of Good Hope [c].

4. Root perennial, fibrous. Culms a palm high, ſeveral, covered on every ſide with the ſheaths of leaves. Leaves ſpreading, ſubulate like ſpines, contracted at the baſe, narrower than their ſheaths. Spike glomerate, ovate, pubeſcent. Flowers ſeſſile, many together, pointing nearly one way: calyx eight-flowered, but often only four-flowered, nearly equal; valves acute, ſtiff, ſtriated: outer valve of the corolla ſtiff, ſtriated, acute; inner involute, coloured.

Native of the fields of Malabar [d].

5. Root perennial. Leaves even, three on the culm, which is of the thickneſs of a fowl's quill, a foot and half in height, and even. Panicle in form of a ſpike, as it were conglomerate, narrower at top, a palm in length, the colour of chaff. Flowers always twin, depreſſed. Calyx nearly the length of the flower, containing about five flowers, the outer valve much attenuated: corolla oblong, awnleſs.

Found at the Cape by Sparrmann [e].

6. The calyx contains one floret only, which has but one ſtyle, which is longer than the ſtamens. The ſtructure of the piſtil marks an affinity with *Nardus*, which is confirmed by its habit [f].

Marſhes in Eſſex, and other parts of the ſea-coaſt, very common; alſo in Portugal.

It is perennial, and flowers from july to ſeptember.—This was confounded with the firſt ſpecies, but is certainly diſtinct from it.

7. Native of North America. Introduced 1781, by Mr. William Curtis. It is perennial, and flowers in july and auguſt [g].

Flowers four-cleft eight-ſtamened.

3. Dais diſperma.
Foreſt. flor. auſtr. n. 192.
Flowers eight and ten-ſtamened; leaves ovate-lanceolate, acuminate, nerveleſs.

DESCRIPTIONS, *&c.*

1. Leaves oppoſite, obovate, quite entire, ſmooth, petioled. Flowers in a bunch aggregate, terminating, pubeſcent; with a gemmaceous, four-valved involucre. It is allied to Paſſerina [h]. The fruit is a ſmall nut of an ovate-acuminate form, with a thin bark over it, and cloathed with the permanent corolla: the epidermis is membranaceous, pale, diaphanous, thickening on each ſide into a prominent, whitiſh edge, eaſily ſeparating: ſhell bony, thin, brittle, livid-white on the outſide, black within; one-celled and valveleſs [i].

Native of the Cape of Good Hope.—Introduced 1776, by Mr. James Gordon [k]; but has long been in the Dutch gardens.

2. Leaves oppoſite, elliptic-oblong, acuminate, petioled, even. Involucre one or two, terminating, peduncled, ſhorter than the flowers, which are ſmooth. Stamens placed upon the tube, and longer than the corolla.—Native of India [l].

3. Native of Tongatabu [m].

PROPAGATION AND CULTURE.

1. This ornamental green-houſe ſhrub of the deciduous kind, not having yet produced any perfect ſeeds with us, as it does in Holland, and no other way having been yet diſcovered of increaſing it freely, it keeps up a very high price among the nurſery-men [n].]

OBS. *The essence of the genus consists in having the filaments united in two equal vertical bodies, separated at top and bottom.*

ESSENTIAL CHARACTER.

Filaments two four-cleft at top. *Fruit* pedicelled, not opening, leguminose, membranaceous-compressed.

SPECIES.

1. Dalbergia Lanceolaria.
Lin. fyst. 641. *Suppl.* 316.
Noel-valli. *Rheede malab.* 6. 39. *t.* 22.
Leaves pinnate; leaflets elliptic hairy underneath; fruits lanceolate.

2. Dalbergia Monetaria.
Lin. fyst. 641. *Suppl.* 317.
Leaves ternate, leaflets smooth, ovate; fruits oval veinless.

DESCRIPTIONS, *&c.*

1. This is a tree, with wand-like pendulous hairy branchlets. Leaves alternate, unequally pinnate; leaflets elliptic, alternate, remote, from ten to sixteen, quite entire, waved, smooth underneath, hirsute above, veinless, small: petioles hairy. Racemes axillary, hairy, branched. Flowers ferruginous. Calyx rough with hairs; the teeth almost equal. Corolla larger than in the second sort: standard more dilated. Filaments two, lateral, four-cleft at the end, with the rudiment of a fifth on each side, but without any loose or single filament, such as the other species has. Style bent upwards. The fruit is a membrane, exactly the figure of a little lance, attenuated at the base, not opening, not divisible into two skins by a knife, the length of a finger or less. In the middle of this membrane a single compressed oval seed is immersed; if there are two seeds, they are placed at a distance from each other longitudinally.

Native of Malabar and Ceylon, and observed there by Koenig.

2. This is a shrub. Leaflets petioled, quite entire, veined, acuminate, alternate. Peduncles several, axillary, spiked, directed one way, toothed at bottom where the flowers have fallen. Flowers extremely minute, white. Calyx blunt, with five small equal teeth. Filaments two, lateral, equal, four-cleft at top, with a third which is single below the germ; hence there are nine filaments: anthers nine, globular, twin. Style filiform, erect: stigma headed. The fruit is of an oval form, like a piece of coin, compressed, cartilaginous within, one-celled, deciduous, not opening. Seed single, compressed, kidney-form. The root when cut yields a purple juice. The wood is red. It yields a resin that resembles Dragon's-blood.—Native of Surinam, in wet places [a].

DALEA. See *Eupatorium*, *Lippia*, and *Psoralea*.]

DALECHAMPIA. (*Given by Plumier, in honour of Jacobus Dalechampius, a physician of Lyons; a commentator on Dioscorides and Pliny; author of Historia Plantarum*, 1587.)

Lin. gen. n. 1081. *Reich.* 1179. *Schreb.* 1460. *Plum.* 38. *Jacqu. amer.* 252. *Juss.* 392.

Class. 21. 9. Monoecia Monadelphia.

Nat. order of *Tricoccae.—Euphorbiae.* Juss.

GENERIC CHARACTER.

Involucre common exterior smaller: *leaflets* four, lanceolate, spreading.

Interior very large: *leaflets* two, heart-shaped, three-cleft, converging.

* For the *male* flowers a footstalked *umbel*, simple, ten-flowered, shorter than the interior involucre.

CAL. *Involucel* two-leaved, erect, blunt: *leaflets* somewhat three-lobed.

Scales numerous, obovate, pressed in an imbricate manner to the exterior side of the involucel, and of the same length with it.

Perianth proper, five-leaved, footstalked; leaflets ovate, acute; deciduous.

COR. none.

STAM. *Filaments* very many, growing together into a column longer than the calyx. *Anthers* roundish.

* In the *females* three florets within the same common *involucre*, approximate to the inferior side.

CAL. *Involucel* three-leaved; *leaflets* emarginate, small. *Perianth* proper, inferior: *leaflets* eleven, linear, toothed, acute, converging, permanent.

COR. none.

PIST. *Germ* roundish, shorter than the perianth. *Style* filiform, ascending, length of the males. *Stigma* somewhat headed, perforated.

PER. *Capsule* roundish, three-berried, three-celled; cells two-valved.

SEED solitary, globose.

ESSENTIAL CHARACTER.

Outer common *involucre* with four leaflets; inner with two trifid leaves.

MALE. *Umbellule* ten-flowered: *involucel* two-leaved; with numerous chaffs. *Proper perianth* five-leaved. *Cor.* none. *Filaments* very many, connate.

FEM. *Florets* three. *Involucel* three-leaved. *Proper perianth* with eleven leaflets. *Cor.* none. *Style* filiform. *Caps.* tricoccous.

SPECIES.

1. Dalechampia colorata. *Coloured Dalechampia.*
Lin. fyst. 862. *Suppl.* 421.
Leaves quite entire.

2. Dalechampia scandens. *Climbing Dalechampia.*
Lin. spec. 1423. *fyst.* 862. *Reich.* 4. 181. *suppl.* 421. *mant.* 496. *hort. cliff.* 485. *Jacqu. amer.* 252. *t.* 160. *pict.* 123. *t.* 239. *Plum. gen.* 17. *amer.* 89. *t.* 101. (Lupulus).
Leaves trifid serrate.

DESCRIPTIONS, *&c.*

[1. This resembles the second species, and the leaves are three-lobed, but less deeply cut and not serrate. The involucre is more oblong, resembling a petal, or coloured, not cordate at the base or green.

Found in New Granada, by Mutis [b].

2. Stem branched, hairy, the hairs standing out. Leaves alternate, petioled, remote, cordate-three-parted, much veined, wrinkled, serrate, pubescent, lobes lanceolate: petioles round, slightly channelled, the length of the leaf: the genuine stipules semi-cordate, reflex, short; besides these there are two spurious stipules from the sinus at the base of the leaf, which are subulate, erect and small. Peduncle axillary, solitary, very short [c].

Native of the West Indies. Introduced 1785 by Mr. Alexander Anderson. It flowers in june and july [d].

Mr. Miller has a plant under the name of Dalechampia scandens,] a native of Jamaica, whence Dr. Houstoun sent him the seeds, which succeeded, flowered, and perfected seeds in the Chelsea garden. It seems to be different from the species here set down; having a smooth fruit, with a hispid calyx (or involucre). Mr. Miller describes it as having a root composed of many fibres, and extending to a great distance; from which arise several weak twining stalks, that fasten themselves to neighbouring plants, and mount up to a considerable height. At each joint is one smooth three-lobed leaf, resembling that of the Hop; the two side lobes are oblique to the midrib, but the middle one is equal. The flowers are produced from the side of the stalks, three or four growing upon each peduncle: they are of an herbaceous colour and small; with a double involucre, made up of two rows of leaves, which are narrow, and armed with small bristly stinging hairs.

PROPAGATION AND CULTURE.

These plants are propagated by seeds sown early in the spring on a hot-bed, transplanted into small pots when three inches high, plunged into a bark-bed, and frequently watered. They should be afterward removed into larger pots, and placed at the back of the bark-stove, where they may have an

[a] Linn. suppl. [b] Linn. [c] Hort. kew.

espalier or trellis to run up. They seldom continue more than two years.]

ESSENTIAL CHARACTER.

Filaments two four-cleft at top. *Fruit* pedicelled, not opening, leguminose, membranaceous-compressed.

SPECIES.

1. Dalbergia Lanceolaria.
Lin. fyst. 641. *suppl.* 316.
Noel-valli. *Rheede malab.* 6. 39. *t.* 22.
Leaves pinnate; leaflets elliptic hairy underneath; fruits lanceolate.

2. Dalbergia Monetaria.
Lin. fyst. 641. *suppl.* 317.
Leaves ternate, leaflets smooth, ovate; fruits oval veinless.

DESCRIPTIONS, *&c.*

1. This is a tree, with wand-like pendulous hairy branchlets. Leaves alternate, unequally pinnate; leaflets elliptic, alternate, remote, from ten to sixteen, quite entire, waved, smooth underneath, hirsute above, veinless, small: petioles hairy. Racemes axillary, hairy, branched. Flowers ferruginous. Calyx rough with hairs; the teeth almost equal. Corolla larger than in the second sort: standard more dilated. Filaments two, lateral, four-cleft at the end, with the rudiment of a fifth on each side, but without any loose or single filament, such as the other species has. Style bent upwards. The fruit is a membrane, exactly the figure of a little lance, attenuated at the base, not opening, not divisible into two skins by a knife, the length of a finger or less. In the middle of this membrane a single compressed oval seed is immersed; if there are two seeds, they are placed at a distance from each other longitudinally.

Native of Malabar and Ceylon, and observed there by Koenig.

2. This is a shrub. Leaflets petioled, quite entire, veined, acuminate, alternate. Peduncles several, axillary, spiked, directed one way, toothed at bottom where the flowers have fallen. Flowers extremely minute, white. Calyx blunt, with five small equal teeth. Filaments two, lateral, equal, four-cleft at top, with a third which is single below the germ; hence there are nine filaments: anthers nine, globular, twin. Style filiform, erect: stigma headed. The fruit is of an oval form, like a piece of coin, compressed, cartilaginous within, one-celled, deciduous, not opening. Seed single, compressed, kidney-form. The root when cut yields a purple juice. The wood is red. It yields a resin that resembles Dragon's-blood.—Native of Surinam, in wet places[a].

DALEA. See *Eupatorium*, *Lippia*, and *Psoralea*.]

DALECHAMPIA. (*Given by Plumier, in honour of Jacobus Dalechampius, a physician of Lyons; a commentator on Dioscorides and Pliny; author of Historia Plantarum*, 1587.)

Class. 21. 9. Monoecia Monadelphia.

Nat. order of *Tricoccae.—Euphorbiae.* Juss.

GENERIC CHARACTER.

Involucre common exterior smaller: *leaflets* four, lanceolate, spreading.

Interior very large: *leaflets* two, heart-shaped, three-cleft, converging.

* For the *male* flowers a footstalked *umbel*, simple, ten-flowered, shorter than the interior involucre.

CAL. *Involucel* two-leaved, erect, blunt: *leaflets* somewhat three-lobed.

Scales numerous, obovate, pressed in an imbricate manner to the exterior side of the involucel, and of the same length with it.

Perianth proper, five-leaved, footstalked; leaflets ovate, acute; deciduous.

COR. none.

STAM. *Filaments* very many, growing together into a column longer than the calyx. *Anthers* roundish.

* In the *females* three florets within the same common *involucre*, approximate to the inferior side.

CAL. *Involucel* three-leaved; *leaflets* emarginate, small. *Perianth* proper, inferior: *leaflets* eleven, linear, toothed, acute, converging, permanent.

COR. none.

PIST. *Germ* roundish, shorter than the perianth. *Style* filiform, ascending, length of the males. *Stigma* somewhat headed, perforated.

PER. *Capsule* roundish, three-berried, three-celled; cells two-valved.

SEED solitary, globose.

ESSENTIAL CHARACTER.

Outer common *involucre* with four leaflets; inner with two trifid leaves.

MALE. *Umbellule* ten-flowered: *involucel* two-leaved; with numerous chaffs. *Proper perianth* five-leaved. *Cor.* none. *Filaments* very many, connate.

FEM. *Floscules* three. *Involucel* three-leaved. *Proper perianth* with eleven leaflets. *Cor.* none. *Style* filiform. *Capf.* tricoccous.

SPECIES.

1. Dalechampia colorata. *Coloured Dalechampia.*
Lin. fyst. 862. *suppl.* 421.
Leaves quite entire.

Leaves trifid serrate.

DESCRIPTIONS, *&c.*

1. This resembles the second species, and the leaves are three-lobed, but less deeply cut and not serrate. The involucre is more oblong, resembling a petal, or coloured, not cordate at the base or green.

Found in New Granada, by Mutis[b].

2. Stem branched, hairy, the hairs standing out. Leaves alternate, petioled, remote, cordate-three-parted, much veined, wrinkled, serrate, pubescent, lobes lanceolate: petioles round, slightly channelled, the length of the leaf: the genuine stipules semi-cordate, reflex, short; besides these there are two spurious stipules from the sinus at the base of the leaf, which are subulate, erect and small. Peduncle axillary, solitary, very short[c].

Native of the West Indies. Introduced 1785 by Mr. Alexander Anderson. It flowers in june and july[d].

Mr. Miller has a plant under the name of Dalechampia scandens, a native of Jamaica, whence Dr. Houstoun sent him the seeds, which succeeded, flowered, and perfected seeds in the Chelsea garden. It seems to be different from the species here set down; having a smooth fruit, with a hispid calyx (or involucre). Mr. Miller describes it as having a root composed of many fibres, and extending to a great distance; from which arise several weak twining stalks, that fasten themselves to neighbouring plants, and mount up to a considerable height. At each joint is one smooth three-lobed leaf, resembling that of the Hop; the two side lobes are oblique to the midrib, but the middle one is equal. The flowers are produced from the side of the stalks, three or four growing upon each peduncle: they are of an herbaceous colour and small: with a double involucre, made up of two rows of leaves, which are narrow, and armed with small bristly stinging hairs.

Flowers aggregate ſeſſile terminating, leaves oblong very blunt villoſe underneath.

DESCRIPTIONS, *&c.*

The ſpecies of this genus are ſhrubs of no great height. The flowers axillary in ſome, at the ends of the branches in others; in ſome ſolitary, in others glomerate. The genus is very nearly allied to *Paſſerina*, and they are ſcarcely diſtinguiſhable from the flower; only the ſtyle is filiform and as long as the tube of the corolla in the *Paſſerina*, whereas in the *Daphne* there is little or no ſtyle.

The flowers are not always three together, but ſometimes two, four or five[a]. The terminating buds produce leaves, and the lateral buds flowers[b].]

1. The Mezereon is a ſhrub, growing (in gardens) to the height of five or ſix feet, with a ſtrong woody ſtalk, putting out many woody branches on every ſide, ſo as to form a regular head. The flowers come out very early in the ſpring, before the leaves, in cluſters all round the ſhoots of the former year. The leaves are ſmooth, about two inches long, and three quarters of an inch broad in the middle, placed without order.

[This ſhrub is ſeldom more than three or four feet high even in gardens, but in its wild ſtate it is from one to two feet in height: the branches then are not numerous; they are very flexible; the leaves are entire and of a pale green.

The fruit is a ſuperior berried drupe, firſt green, then red, of an ovate-globular form; with a thin ſucculent pulp, and a cruſtaceous, thin, brittle, black ſhining ſhell. It is however commonly called a berry[c].

Native of Lapland, Sweden, Denmark, Germany, Switzerland, France, Carniola, Savoy, Piedmont, Great Britain. Mr. Miller is the firſt who mentions that it is a native of our iſland, namely near Andover in Hampſhire. Since that it has been found by Mr. Woodward at Laxfield in Suffolk; by Mr. White in Selborne-hanger, Hants; and it has been frequently obſerved in the beech woods of Buckinghamſhire. As it has eſcaped all our old herbariſts, and even the indefatigable Ray and his immediate ſucceſſors; and birds are remarkably fond of the berries; I ſhould ſuſpect that they may have diſſeminated this beautiful ſhrub: unleſs we may ſuppoſe that it remained unnoticed on account of its early flowering, before herbariſts ſallied forth on their vernal excurſions.

Gerarde ſays that he had plenty thereof for his garden from Elbing in Poland. He calls it Germaine Olive Spurge or Spurge Olive, Spurge Flax,

[a] Reich. and Juſſ. [b] Linn. ſpec. [c] Gærtner.

and

and Dwarf Bay, and ſays that the Dutch call it Mezereon. Parkinſon calls it Dwarf Bay or flowering Spurge. In German it is *Kellerhals*, *Kellerhere*, *Kellerkraut*, &c. In Dutch, *Peperboompje*. In Daniſh, *Kiellerhals*. In Swediſh, *Kiellerhals*. In French, *Laureole gentille* or *femelle*, *Bois gentil*, *Bois joli*. In Italian, *Laureola femina*, *Dafnoide*, *Camelea*, *Calmolea*, *Biondella*. In Spaniſh, *Laureola hembra*. In Portugueſe, *Loireola femea*, or *Mezereo major*. In Ruſſian, *Wolttschje lako*.

The branches make a good yellow dye.

The whole of this vegetable is extremely acrid, eſpecially when freſh, and if retained in the mouth excites great heat and inflammation, particularly of the throat and fauces. The berries when ſwallowed prove a powerful poiſon not only to man but to many quadrupeds. Both the bark and the berries of Mezereon, in different forms, have been long uſed externally in caſes of obſtinate ulcers and ill-conditioned ſores. In France the bark is uſed as an application to the ſkin, which under certain management, produces a ſerous diſcharge without bliſtering: and is thus rendered uſeful in chronic caſes of a local nature, anſwering the purpoſe of what is called a perpetual bliſter, while it occaſions leſs pain and inconvenience. In our own country the Mezereon has been principally employed in ſyphilitic caſes, and in this way Dr. Donald Monro was the firſt who gave teſtimony of its efficacy in the ſucceſsful uſe of the Liſbon diet-drink. Afterwards ſeveral caſes were publiſhed by Dr. Ruſſel, then phyſician to St. Thomas's hoſpital, fully eſtabliſhing the utility of the bark of Mezereon in venereal nodes. In the above caſes the decoction of the root was made uſe of; but in ſome caſes it has been found neceſſary to join with it a ſolution of ſublimate. Dr. Cullen ſays that Dr. Home has not only found the decoction of Mezereon to cure ſchirrous tumours which remain after the lues venerea, and after the uſe of mercury, but that it has alſo healed ſchirrous tumours from other cauſes. The conſiderable and long-continued heat and irritation that is produced in the throat when Mezereon is chewed, induced Dr. Withering to give it in a caſe of difficulty of ſwallowing, ſeemingly occaſioned by a paralytic affection: the patient was directed to chew a ſlice of the root as often as ſhe could bear it, and in about a month ſhe recovered her power of ſwallowing: ſhe had ſuffered the above complaint upwards of three years, and was greatly reduced, being totally unable to ſwallow ſolids, and liquids but very imperfectly [a].

There are two principal varieties of the Mezereon; one with a white flower ſucceeded by yellow berries; the other with peach-coloured flowers and red fruit: the latter has ſometimes flowers of a much deeper red.

There is alſo a variety with variegated leaves. The flowers appear in february or march, in mild ſeaſons in january. The berries ripen in june, [if they are not eaten by birds.—Monſ. Villars mentions another variety, with the leaves a little villoſe, or having ſmall hairs at their baſe, and the flowers four together. He remarks, that the parts of fructification are ſo perfectly formed, the year before the flowers unfold themſelves, that the character may eaſily be determined by the naked eye.]

2. This riſes to the height of three or four feet, with a ſingle ſtalk, covered with a light-coloured bark. The flowers come out in cluſters on the ſides of the ſtalk, and being of an herbaceous colour make but little appearance: they appear early in the ſpring, and are ſucceeded by ſmall berries which are yellowiſh when ripe.

[According to Vahl, it is a low little ſhrub, branching only at bottom: the branches are erect, quite ſimple, ſmooth and even. Leaves very ſmooth, erect, glaucous. Flowers ſolitary, ſometimes two or even three together, ſhorter than the leaf, dioecous, four-ſtamened. D. dioica (n. 9.) has a very branching ſtem, the branches warted, the leaves more crowded together and ſhorter, broader towards the top, and not narrowing to both ends.

D. Thymelæa is native of Spain, Italy, and the South of France. Vahl found it in great abundance on the confines of New Caſtille towards Navarre.

3. Stems ſimple. Leaves alternate, remote, almoſt naked, annual, ſubmucronate. Flowers axillary, narrow, five or ſewer, with a filiform pubeſcent tube, ſhorter than the leaves. It ſeems to be different from the preceding ſpecies, and was found in Auſtria by Jacquin [b].

4. This is a ſhrub with alternate branches. Leaves like thoſe of Knot-graſs, ſcarcely petioled, with white remote hairs on both ſides, fewer on the upper ſurface, and more towards the edges. In the axils are very many rudiments of branchlets, whence it is as it were verticilled. Flowers narrow, ſmall, ſhorter than the leaves. Obſerved in Spain and Portugal by Alſtroemer [c].]

5. This is a low ſhrubby plant, which ſends out ſeveral weak ſtalks from the root, about a foot long, and ſpreading about irregularly; theſe ſeldom become woody in England, but are tough and ſtringy, covered with a light bark: the leaves are ſmall, very ſoft, white and ſhining like ſattin, and ſit pretty cloſe to the ſtalks: between theſe white flowers come out in thick cluſters. [They are commonly two or three together, very ſeldom ſolitary, bell-ſhaped, ſilky on the outſide, but yellowiſh within, imbricated at the baſe with four or more ovate keeled ſcales [d].

Native of the South of France. Cultivated by Mr. Miller in 1739 [e].

Vahl has another ſpecies (ſymb. 3. 53.) which he names *Daphne nitida*, and which he found on the calcareous mountains of Tunis. It has the appearance of the Tartonraira, but the leaves are only one-ſixth of the ſize, and nerveleſs; there are no ſcales at the baſe of the calyx; and the branches are rough, but not ſquarroſe with the permanent floral ſcales.]

6. This riſes about three feet high. The flowers come out in cluſters from the ſides of the branches early in the ſpring, and are ſucceeded by ſmall roundiſh berries, which turn red when ripe.

[The root fixes itſelf deeply in the crevices of the rocks. The little ſtems are ſhrubby and upright, ſcarcely a palm in height, as it were brachiate, leafy and flowering at the top. Leaves lanceolate or obovate, uſually emarginate, hoary with hairs when viewed with a glaſs, as are alſo the calyxes and fruits. The younger leaves appear hirſute to the naked eye, but afterwards appear bald unleſs to the magnifier [f].

Native of the South of France, the mountains near Geneva, Auſtria, and Italy. Cultivated in 1759, by Mr. Miller [g].]

7. This is a low evergreen ſhrub, riſing with ſeveral ſtalks to the height of two or three feet, dividing at top into ſeveral branches. The leaves come out irregularly on every ſide, ſit pretty cloſe to the branches, are thick, ſmooth and of a lucid green. Among theſe, towards the upper part of the ſtalks, come out the flowers in ſmall cluſters; they are of a yellowiſh green, and appear ſoon after chriſtmas, if the ſeaſon be not very ſevere. They are ſucceeded by oval berries, which are green till june, when they ripen and turn black, ſoon after which they fall off.

[The whole plant is flexible. The leaves are crowded at the ends of the branches, they are green all the winter, and are renewed in ſpring, after flowering time [h]. The racemes are nodding, with concave alternate bractes, not having any flowers in their axils. Flowers five terminating, heaped into an umbellet. The flowers are of a dull colour, their ſcent is unpleaſant, and they appear at a gloomy ſeaſon [i].

[a] Woodville.

[b] Linn. mant. [c] Linn. ſyſt. [d] Vahl.
[e] Hort. kew. from Mill. dict. [f] Gouan. [g] Hort. kew.
[h] Lightf. and Villars. [i] Linn. ſyſt.

Native of Britain, France, Switzerland, Auſtria, and Carniola. Gerarde did not know that it grows wild in England, although it is common enough with us in woods and hedges.

Notwithſtanding Linneus's cenſure, the Spurge Laurel is a ſhrub of ſome value, on account of the lucid green of the leaves, which continuing all the year, render it ornamental in winter; but particularly becauſe it flouriſhes under trees, and is therefore very proper to fill up ſpaces in plantations.

[Very happy effects are ſaid to have been ſometimes experienced from this plant in rheumatic fevers: it operates as a briſk and rather ſevere purgative: it is an efficacious medicine in worm caſes; but on account of its acrimonious nature, it ſhould be uſed by ſkilful practitioners. The whole plant has the ſame qualities, but the bark of the root is the ſtrongeſt. Dr. Alſton fixes the outſide doſe at ten grains [a].

Some other ſpecies of this genus are poſſeſſed of nearly ſimilar powers with the Mezereon and the Spurge Laurel, and are uſed in ſimilar caſes, but, like the former, require caution in their uſe, and ſhould not be truſted to inexperienced hands.

8. Stem about two feet high, branched ſometimes from the very bottom, about three lines in thickneſs, very pliable, covered with a gray bark. Leaves towards the top without order, of the figure and conſiſtence of thoſe of the Lemon, the largeſt four inches long and two wide, pointed at each end, ſmooth, bright green and ſhining, having a thick midrib underneath. At the end of april young ſhoots terminated by new leaves puſh from the extremities of the ſtems and branches, among which ſpring the flowers commonly in pairs on a peduncle nine or ten lines in length. The corolla is of a greeniſh yellow inclining to lemon colour; it has a ſweetiſh ſmell which is ſoon loſt [b].

Native of Pontus, firſt obſerved there by Tournefort: alſo in Siberia, by Guldenſtadt, flowering in autumn [c].

9. This is a ſhrub a foot in height, ſtiff and branched, with a corky bark. Branches alternate, erect, ſtiff, roughened by the ſcars of fallen leaves. Leaves crowded ſo as almoſt to be imbricate, very ſmooth, reſembling thoſe of Myrtle, four lines long, and hardly a line broad, not ciliate. Flowers ſeſſile, always two together, one flowering later than the other, dioecous: corolla yelloviſh white or paleſulphur colour, with a bellying tube.

Native of the Pyrenees, where it was firſt obſerved by Dr. Peck, a phyſician of Narbonne; and in 1768 by Gouan [d].

10. This is a ſmall ſhrub, a ſpan's length, according to Oſbeck, or three feet high, with aſcending branches, according to Loureiro. Leaves commonly acute, quite entire, petioled. Peduncle very ſhort, with from ſix to eight ſeſſile flowers at top [e]. Oſbeck ſays, that the eight filiform ſtamens are as long as the corolla or piſtil; whereas according to Loureiro, they are uſually ten in number, concealed within the tube, placed in two rows, in the upper ſix, in the lower four.

Native of China, about Canton, but probably from Nankin, ſince it is commonly called the Nankin ſhrub [f].]

11. This is a very humble ſhrub, ſeldom more than one foot high. Stems branched. Leaves narrow lanceolate, placed without order. The branches are terminated by ſmall cluſters of purple flowers, which ſtand erect. The tube of the corolla is longer and narrower than in the Mezereon. The flowers emit a pleaſant odour, and appear early in the ſpring.

[The leaves are ſometimes acute, ſometimes obtuſe and emarginate [g]. It varies with white flowers [h].

Native of France, Germany, Switzerland, Auſtria, monte Baldo, the Pyrenees, and Hungary. Cultivated in 1739 [i].]

12. This riſes with a ſhrubby ſtalk about two feet high, dividing into ſmall branches, terminated by panicles of flowers, which are much ſmaller than thoſe of the Mezereon, having ſwelling tubes contracted at the mouth; they appear in june.

[The ſtems ſpread on the ground; the leaves are annual and ſmooth; the flowers heaped, ſurrounded with leaves, ſweet-ſmelling, red above [j].

Native of the South of France, Spain and Italy, flowering twice in the year.—Cultivated in 1597, by Gerarde [k]: by whom it is called Spurge Flax or Mountain Widow Wayle: by Parkinſon Spurge Olive.]

13. This riſes to the height of five or ſix feet, dividing at top into ſeveral erect branches, covered with a white bark, and terminated by woolly heads, out of which the flowers come in ſmall cluſters: they are white, have oblong tubes, and the ſegments of the border are obtuſe and ſpreading.

Native of the Cape of Good Hope.

[14. Stem ſhrubbyiſh, compound.—Native of the Levant [l].

15. Native of the Society iſles [m]. It is not certain whether it be diſtinct from *D. indica* [n].

16. Branches tomentoſe, hoary.—Native of Tonga Tabu [o], or Namoka [p], in the South Seas.

17. Stem becoming ſhrubby, dichotomous, ſmooth, naked, erect. Branches like the ſtem, from divaricate erect. Leaves at the top of the laſt branchlets, approximating, ſeſſile, acute, quite entire, ſpreading, bent back at the tip; deep green on the upper ſurface, with a groove along the middle; paler underneath; unequal, thick, evergreen, an inch in length. Flowers about eleven. Bractes between the leaves and the umbel, lanceolate, about ten, entire, concave, green, ſmooth, only half the length of the calyx. Corolla ſmooth; tube purple, a line in length, diviſions of the border ſubcordate-ovate, obtuſe, on the outſide purple and ſomewhat wrinkled, on the inſide ſcarlet, ſpreading, alternately incumbent. Filaments inſerted below the mouth: anthers oblong, four included, and four ſtanding out. Germ ſmooth: ſtyle none: ſtigma ſimple, ſeſſile, globular, retuſe with a tranſverſe groove, whitiſh. Seed ovate, ſmooth.—It differs from the *Paſſerinas* in having no ſtyle; from *D. indica* in having a ſeſſile head, and alternate leaves.

Native of Japan, flowering there in february [q]; alſo of China, where it is cultivated on account of the grateful odour of the flowers.—Introduced 1771, by Benjamin Torin, Eſq. and flowers here from december to march [r].

18. A tree or ſhrub with alternate round branches, leafy at the end; covered with a ſmooth brown outer bark, and a very filamentoſe, ſilky, white inner bark, as in moſt of the other ſpecies. *Leaves* on ſhort petioles, acute, quite entire, veined, paler underneath, deciduous; the primordial ones minute, like ſtipules, ſilky on the back, and abortive. There are no proper ſtipules. *Flowers* in ſolitary heads, from the axils of the leaves of the former year. A pair of ſmall, erect, linear, obtuſe bractes, hairy on the outſide, at the baſe of the peduncles; which are an inch long, round, ſmooth, growing gradually thicker to the end. Involucre two-leaved, many-flowered; leaflets obovate, obtuſe, concave, quite entire, a little longer than the flowers, pubeſcent on the outſide, obſcurely nerved. Calyx ſubcylindric, white, very hirſute on the outſide, divided into four acutiſh, ſmall ſegments; the two inner ſmaller and ſmooth. Germ ſmooth at the ſides, but terminated by numerous briſtles, the length of the ſtyle. Stigma rather large, ſmooth.—On account of the involucre, it ſhould ſeem as if it might be placed in the genus *Daia*; but ſince it agrees with the Daphnes in the ſtructure of the flower, and number of the parts; and ſince the involucre itſelf, reſembles more the bractes in ſome ſpecies of Daphne, than the involu-

[a] Withering. [b] Tournefort. [c] Pallas. [d] Gouan illuſtr. [e] Linn. ſyſt. Oſb. Lour. [f] Loureiro. [g] Gouan. [h] Cluſius. [i] Hort. kew. from Mill. dict.

lucre of Dais, it ſeems better to refer it to this genus[h].

Thunberg gathered it in the iſland of Java.

19. This ſhrub ſeems to have the habit of Mezereum. The ſtems are ſtraight, ſlender, covered with an even teſtaceous bark; the lower branches are ſhort, flowering, hairy next the flowers; the upper ones which continue the growth of the ſhrub, are ſmooth. Leaves alternate, quite entire, drawn to a point at the baſe, ſeſſile; on the flowering twigs oblong-ovate, ſmaller, growing up to the flowers; on the barren branches more oblong, very like the leaves of Mezereon, and emulating their conſiſtence. Flowers moſtly five together, collected into a head, without any bractæ or ſtipules. Corolla white, with a longiſh tube, ſwelling at the baſe, pubeſcent with many hairs, and a ſpreading border, with lanceolate ſmooth ſegments: anthers in a double row in the tube on very ſhort filaments: germ ſubglobular, with an obtuſe ſtigma.

This elegant ſhrub was diſcovered by Patrin in the Altaic alps.

Palias has another ſpecies allied to this and the Cneorum, which he calls *Daphne caucaſica*. It was obſerved by Guldenſtadt by the river Cſani near Achalgory, flowering with the Cherry and Pear at the end of april, and no where elſe on mount Caucaſus. It is a ſhrub two or three feet high and more, with wand-like branches, diffuſed, and covered with a brown bark. Leaves crowded, ſeſſile, oblong-lanceolate, ſomewhat waved, glaucous, quite entire, blunt at the end, and terminated by a little thorn. The flowers are in terminating, ſeſſile, naked umbels, about twenty together; they are white, ſucculent, the ſize of Lilac flowers, with the ſmell of the Hyacinth: tube long, green: ſtamens incloſed within the tube, in two rows, four at the throat, and four in the middle of the tube, on very ſhort filaments[i].

20. Stem three feet high, ſimple, with aſcending branches. Leaves quite entire, ſmooth, on ſhort petioles. Flowers yelloviſh. Common calyx three-leaved, three-flowered. Corolla tubular, four or five-cleft.

Native of China, in the ſuburbs of Canton.

21. This is a tree, ten feet high, with aſcending branches, and a very tough bark like that of Hemp. Leaves ovate-lanceolate, quite entire, ſmooth. Flowers yellow, in ſubterminating umbels. Corolla ſalver-ſhaped, with a long tube, and a ſmall border, with ovate ſegments. Filaments in two rows within the tube, with oblong anthers. Berry ovate, red, ſmall.—Native of the woods of Cochinchina.

An excellent writing paper is made from the bark, prepared like Hemp. Shapeleſs, heavy, brown, reſinous, woody fragments, reſembling the wood of Aloe, and having ſomewhat of its ſmell in the fire, are frequently found within the trunk of this tree near the root. The bark and root may be uſed medicinally in the Aſcites, *&c.* without any of that danger to which the other ſpecies are liable[k].

22. Stems three feet high, much branched, the branches often forked: bark tough, wrinkled, void of down or hair, except on the younger branches. Leaves evergreen, alternate, on ſhort foot-ſtalks, entire, a little revolute on the edge, having a ſilky down underneath. Bractæ obovate, obtuſe, externally downy. Calyx red, with a ſilky down on the outſide; its diviſions ſpreading, a little obtuſe. Germ clothed with upright briſtles, as in D. pendula, and there are nectariferous glands at the baſe.

Native of low hills in the South of Italy: it covers the hills and fields on the banks of the Vulturnus, as furze does our commons in England; and ſince it thrives with us like the Myrtle, it is a valuable addition to our ſhrubs. Dr. Smith gathered it in march 1787 near Caſerta, in company with Mr. Græffer[l].

23. This is a tree, the wood of which is white. Leaves about four inches long, and two and a half broad near the baſe where broadeſt, having one middle and ſeveral tranſverſe ribs, of a yelloviſh green colour, ſhining, thick and ſmooth. The outer bark is ſmooth, light brown or gray and ſtriated; the inner is ſolid and white, of a very fine texture, tough and diviſible into ſeveral coats or layers, which may be drawn out into thin webs reſembling lace, and have been actually worn as ſuch. King Charles the Second had a cravat made of it, which was preſented to him by Sir Thomas Lynch then governor of Jamaica. It is there principally uſed for ropes, but would undoubtedly make fine paper, if properly prepared[m].

Native of Jamaica, where it is called Lagetto or Lace-bark tree; and of Hiſpaniola, where it is known by the name of Bois Dentelle. Its place is between the 10th and 11th ſpecies.]

24. This riſes with a woody ſtalk to the height of twenty feet, dividing into many branches, which are covered with a gray rough bark; at the extremity of the branches are produced the peduncles, which are unequal in length, and divide into ſeveral ſmaller, each ſuſtaining a cluſter of ſmall white flowers, which are collected into a head or ſmall umbel, having one general involucre: they are male and hermaphrodite on different trees. The latter are ſucceeded by oval berries, not quite ſo large as thoſe of the common Bay. The leaves of this tree are about two inches long, and one inch broad, rounded at the top and entire, on very ſhort foot-ſtalks. It was diſcovered at La Vera Cruz by Dr. Houſtoun, [and is alſo a native of Jamaica. It was cultivated by Mr. Miller before 1733.

25. Native of Jamaica[n].

The place of this and the foregoing is between the 11th and 12th ſpecies.

26. This is an humble, ſtiff and very branching ſhrub. Branches purple, warted, villoſe at top. Leaves ſeſſile, crowded, thick, obtuſe. Flowers axillary, oppoſite, ſhorter than the leaf. Scales in pairs, oppoſite, minute, at the baſe of the calyx. Segments of the corolla ovate. Gathered by Vahl in the kingdom of Arragon.

Its proper place is between the third and fourth ſpecies.

27. This is a very branching ſhrub. Branches round, brown, villoſe at top. Leaves towards the ends of the branchlets, crowded, ſeſſile, lanceolate-elliptic, veinleſs, quite entire, acute, ſmooth above, villoſe underneath. Flowers purple, five. Tube of the corolla villoſe-ſilky, enlarged at the baſe; the ſegments of the border oblong, obtuſe, ſmooth within, ſhorter by half than the tube. Fruit ſubovate. It differs from D. oleoides in having the leaves villoſe underneath, in the number of flowers, and in the ſegments of the border being oblong. Native of Candia and Naples.

The proper place of this and the next is between the 14th and 15th ſpecies.

28. This is a ſhrub with round, villoſe, naked branches. Leaves towards the ends of the branchlets, approximating, ſeſſile, a little narrower at the baſe, rounded at the end, the younger ones villoſe on both ſides, the reſt only underneath, veinleſs. Flowers ſix. Tube of the corolla villoſe-ſilky on the outſide, gibboſe at the baſe; ſegments oblong, obtuſe. It differs from the foregoing in the form of the leaves, and the whiteneſs of the corolla.—Native of the Levant[o].]

PROPAGATION AND CULTURE.

1. This is propagated by ſeeds, which ſhould be ſown on a border expoſed to the eaſt, ſoon after the berries are ripe; for if they are not ſown till the ſpring following they often miſcarry, and always remain a year in the ground before the plants appear; whereas thoſe which are ſown in auguſt, will grow the following ſpring, ſo that a year is ſaved, and theſe never fail. When the plants come up, they will require no other care but to keep them clean

[h] Smith. [i] Pallas. [k] Loureiro. [l] Smith. [m] Sloane and Browne. [n] Swartz. [o] Vahl.

from

from weeds, and if the plants are not too close together, they may continue in the seed-bed, to have the growth of two summers, especially if they do not make great progress the first year; then at michaelmas, when the leaves are shedding, they should be carefully taken up so as not to break or tear their roots, and planted into a nursery at about sixteen inches row from row, and eight or nine inches asunder in the rows; in this nursery they may remain two years, by which time they will be fit to remove to the places where they are designed to remain for good: the best season to transplant these trees is in autumn, for as these plants begin to vegetate very early in the spring, it is not proper to transplant them at that season. These plants grow best in a light sandy earth which is dry, for in cold wet land they become mossy, and make little progress; so that upon such soils they never grow to any size, and produce few flowers.

Although the berries of this tree are so very acrid, as to burn the mouth and throat of those who may incautiously taste them, yet the birds greedily devour them, as soon as they begin to ripen: so that unless the shrubs are covered with nets to preserve the berries, they will all be destroyed before they are fit to gather.

The Mezereon is a very ornamental shrub in gardens, very early in the spring, before others flower: and where there are plenty of them growing together, they perfume the air to a considerable distance.

7. Spurge-Laurel may also be propagated by seeds, layers or cuttings. The plants may be easily obtained from the woods.

The second, fifth, and twelfth sorts are hardy, and will live through the winters in England in the open air, provided they are in a dry soil and a warm situation. The sixth and eleventh sorts are as hardy as the common Mezereon, so are not in danger of being hurt by frost in England; but they are all very difficult to keep in gardens, because they will not bear to be transplanted. I have several times raised the plants from seeds, which have succeeded well in the places where they were sown, but whenever they were removed, they certainly died, though performed at different seasons, and with the greatest care, and the same has happened to every other person who has raised any of these plants: and some of my correspondents have assured me, they have frequently attempted to remove these plants from their natural places of growth, into their gardens, and have chosen plants of all sizes, from the youngest seedlings to the oldest plants, yet have never succeeded in it; though they have used their utmost care, and have performed it at different seasons. Therefore those who are desirous to have these plants in their gardens, must procure their seeds from the countries where they naturally grow; and when they arrive, they should be immediately sown where they are designed to remain, which for the second, fifth, and twelfth sorts, should be on a very warm dry border, where, if there is a foundation of lime, rubbish, or chalk, under the upper surface of the ground, the plants will thrive better and continue much longer, than in better ground; and all the culture they require, is to keep the place clean from weeds, for the less the ground is stirred near the roots, the better the plants will thrive; for they naturally grow on poor shallow land, and out of crevices in rocks; so the nearer the soil approaches to this, the more likely the plants will be to succeed.

The sixth and eleventh sorts may have a cooler situation; if these are sown where they may have only the morning sun, they will thrive better than in a warmer situation, and the ground near the roots of these should not be disturbed; therefore in the choice of the situation, there should be regard had to this, not to sow them near other plants, which may require transplanting, or to have the ground dug and loosened. The seeds of these plants coming from distant countries, rarely arrive here time enough to sow in autumn, so that when they are sown in the spring, the plants do not appear till the succeeding spring; and I have sometimes had the seeds remain till the second spring in the ground, before the plants have appeared; but as this may be too long for many people to leave the ground undisturbed, they had better put the seeds into small pots of earth, and bury them in the ground the first summer, and in autumn take them up, and sow them where they are to stand; by this method, the seeds will be forwarded to vegetate the following spring.

The sixth sort is a beautiful sweet shrub, and deserves a place in gardens, as much as any of those we cultivate for ornament.

The thirteenth sort grows naturally at the Cape of Good Hope, and requires a good green-house to preserve it. This plant is very difficult to keep or propagate in gardens.

The 14th, 15th, 16th, 17th also require the protection of a green-house.

18, 23, 24, 25. are stove plants, and must be managed in the same manner with Coffee.

DESCRIPTIONS, *&c.*

[These are tall, upright herbs, with alternate unequally-pinnate leaves. The flowers are in spiked racemes, axillary, with one bractæ. The capsule is like that of Reseda, but inferior; and the flower is apetalous. They have the air of Hemp, but the fruit is inferior, and contains many seeds *.]

* Jussieu.

1. This

1. This has a perennial root, from which ariſe ſeveral herbaceous ſtalks, about four feet high, with pinnate leaves placed alternately, each compoſed of three pairs of leaflets, terminated by an odd one; theſe are two inches long, and half an inch broad, ending in acute points, deeply ſerrate, and of a light green. The flowers come out in long looſe ſpikes from the upper part of the ſtalks at the axils, but having no petals make a poor appearance: the anthers of the male flowers being pretty long, and of a bright yellow colour are moſt viſible at any diſtance.

[Capſule inferior, ovate-oblong, crowned with the two ſubulate teeth of the calyx and the three bifid ſtyles, membranaceous, thin, with three or five rounded angles, having no valves, but opening at top with a large round hole[a].

Native of Candia or Crete. Cultivated in 1739, by Mr. Miller[a].

It flowers in June or July, and the ſeeds ripen in ſeptember.

2. Larger. The ſtem rough on every ſide with hairs that ſtand out. Leaflets larger, more alternate, more decurrent and confluent at the baſe[a].

Found in Penſylvania, by Kalm.]

PROPAGATION AND CULTURE.

Theſe plants may be propagated by parting the roots, which ſhould be performed in autumn when the ſtalks decay, but they muſt not be parted too ſmall; they may be planted in any open beds, where they are not under the drip of trees, and will require no other culture but to keep them clean from weeds.

They may alſo be propagated by ſeeds, but theſe ſhould be taken from ſuch plants as grow in the neighbourhood of male plants, otherwiſe they will not ſucceed; and if the ſeeds are not ſown in autumn, they ſeldom grow the firſt year. The ſeedling plants when they riſe, will require no other care but to keep them clean from weeds till autumn, when they may be tranſplanted where they are to grow.

The ſecond ſort is equally hardy with the firſt, but ſhould have a more ſhady ſituation, and a moiſter ſoil.

DESCRIPTIONS, *&c.*

[The ſpecies of this genus have a ſtrong narcotic ſmell; they are all herbs and annual, except the ſixth. The flowers and branches ſolitary.]

1. This ſort ſeldom riſes more than a foot and half high, ſpreading out into many branches. Leaves ſomewhat like thoſe of the common or ſecond ſort, but ſmaller, and ſtanding upon longer foot-ſtalks; the flowers are alſo ſmaller; the fruit is round, and armed with very ſtrong ſharp thorns; the ſeeds are black when ripe.

[This is leſs ſmooth than the common ſort (n. 2.) and the four uppermoſt ſpines of the capſule are very large and erect. It is annual and a native of China[a].

It flowers from july to ſeptember, and was cultivated in 1731, by Mr. Miller[a].

2. *Stem* from one to ſix feet in height, according to the ſoil, but ſeldom more than two feet, round, ſmooth; dividing into many ſtrong, irregular branches, which are hollow, covered with a fine down. *Leaves* from the forking of the ſtem and

[a] Gærtner. [a] Hort. kew. [a] Linn. ſpec. [a] Linn. ſpec. [a] Hort. kew.

branches, ſingle, ſcarcely ſix inches long, petioled, pointed, deep green on the upper ſurface, paler beneath and on the edges, with ſtrong ribs or nerves, unequally ſinuated and toothed about the edge, extending farther down the petiole on one ſide than on the other. Petioles round, downy, ſhorter than the leaves, above faintly channelled. *Flowers* ſingle from the axils, on ſhort pedoncles, upright, (firſt from the forks of the branches, and afterwards near the extremities). Calyx pale green: corolla white: tube greenish, ſhorter than the calyx: lower part of the filaments attached to the tube of the corolla: anthers upright, ſeſſile, of a browniſh yellow colour. Nectary a circular notched gland at the baſe of the germ, which is ſuperior, ſomewhat conical and hiſpid: ſtyle the length of the ſtamens, growing a little thicker towards the top. Seeds blackiſh [2].

Gerarde (1597) informs us, that the Thorne apple was brought in ſeed from Conſtantinople by Lord Edward Zouch.] Mr. Miller ſays, it was probably firſt introduced from Italy or Spain, but it is now become ſo *common* about London and other great towns, as to appear like a native plant, there being few gardens or dunghills without it in ſummer.

[That it is a native of America however we have the moſt undoubted proofs; for in the earth brought with plants from various parts of that extenſive country, we are ſure to have the Thorn-apple come up. Kalm ſays, that it grows about all the villages, and that this and the Phytolacca are the worſt weeds there [3]. Our old writers call it Thorny-apples of Peru.

At night the leaves, particularly the upper ones, riſe up and incloſe the flowers [4]: which appear from july to ſeptember.

Gerarde ſays he firſt diſperſed the ſeeds through this land, and that he made great uſe of it in chirurgerie, as well in burnings and ſcaldings, as alſo in virulent and maligne ulcers, apoſtemes, and ſuch like.

An ointment prepared from the leaves gives eaſe in external inflammations and hæmorrhoids. The Edinburgh college *direct an extract from them; which has been given with great advantage in convulſions and epilepſies; the doſe from two to ſixteen grains a day. Theſe and the ſeeds given internally bring on delirium, tremors, ſwelling, itching, eruption, and inflammation on the ſkin *.

3. This reſembles the common ſort, but is twice the ſize. Stem purpliſh with white dots, divided at an acute angle, ſmooth and even. Corollas pale blue. Leaves more finely toothed, and, if they be ſtatted, cordate [1].

Cultivated 1686, by Mr. Ray *, in his garden at Cambridge.]

4. This riſes with a fine poliſhed purple ſtalk four feet high, dividing into ſeveral branches. Leaves large, ſmooth, ſinuated, on pretty long ſoot-ſtalks. The flowers are produced at the diviſions of the branches; they have large ſwelling tubes, which ſpread very broad at the top, their brims having ten angles, each ending in a long ſlender point. The flowers are of a beautiful purple on their outſide, and a ſattiny white within; ſome of them are ſingle, others have two or three flowers ſtanding one within another, and ſome are double, having four or five petals within each other of equal length, ſo as to appear a full flower at the brim; they have an agreeable odour at firſt, but if long ſmelt to, become leſs agreeable, and are narcotic. The ſeed-veſſel is thick and fleſhy, as are alſo the partitions of the cells: the outſide is covered with blunt protuberancies; and the ſeeds are of a bright brown colour when ripe.

[Stem rufous with white dots or lines *.

Native of the Eaſt Indies and of Egypt. Cultivated 1731, by Mr. Miller *.]

5. This has a ſtrong ſtem three feet high, dividing into many woolly branches: the leaves have only two or three ſlight indentures on their edges; the flowers have long tubes, which extend beyond the bifid calyx, then they ſpread out very broad where the brim is divided into ten obtuſe angles; they are of a pure white above, but the tubes have a tincture of green within: they are ſucceeded by roundiſh fruit, cloſely covered with thorns: the ſeeds are of a light brown colour when ripe.

[The calyx is not angular but columnar, only ſwelling a little *.

Native of Aſia, Africa, and the Canary iſlands. Cultivated 1759, by Mr. Miller *.]

6. This riſes with a woody ſtalk to the height of twelve or fourteen feet, dividing into ſeveral branches. Leaves oblique, ſix inches long, two inches and a half broad in their wideſt part, growing narrower at each end, downy, on long foot-ſtalks, which ſtand nearer to one ſide than the other. The flowers come out at the diviſions of the branches; they have a looſe tubular calyx near four inches long, which opens at the top on one ſide like a ſpathe: the tube of the flower is narrow; but above, it ſwells very large near ſix inches in length, then ſpreads open at the brim, where it is diviſed into five angles, which terminate in very long points; they are white, with ſome longitudinal ſtripes, of a pale yellow on their outſide, and are ſucceeded by round ſmooth capſules, filled with kidney-ſhaped ſeeds.

Native of South America; and one of the greateſt ornaments to the gardens in Chili, where the inhabitants propagate it with great care. When the flowers are fully blown, they make a fine appearance, and a ſingle tree will perfume the air of a large garden.

[Introduced 1783, by Monſ. Thouin *. It had however been cultivated before, both in the Cheſſea garden, and by Lord Petre, from ſeeds ſent over by Dr. Houſtoun.

7. In appearance and ſtature this is like the other annual ſpecies. The leaves reſemble thoſe of *D. Stramonium* or *Tatula*; they are ovate and toothed. The corollas are white [1].

Native of Africa. Introduced 1780, by Monſ. Thouin. It flowers from july to ſeptember [1].]

8. This riſes with a purpliſh ſtem three or four feet high, dividing into ſeveral ſtrong branches. Leaves oblong heart-ſhaped. Stems, branches and leaves covered with ſoft hairs. The flowers come out at the diviſions of the ſtalk and branches, ſtanding erect; they are large, white; and are ſucceeded by oval fruit, covered with long, ſoft, innocuous ſpines, and opening within in four cells, full of brown ſeeds. It grows naturally at La Vera Cruz, whence Mr. Miller received the ſeeds.

PROPAGATION AND CULTURE.

Moſt of the ſpecies, coming from hot countries, require the protection of a ſtove or glaſs-caſe. The ſecond and third only are hardy, and if permitted to ſeed, will furniſh a ſupply of plants for ſeveral years to come; for the ſeeds will be long in the ground, and when turned up to the air will vegetate.

The firſt, fourth, and fifth may be raiſed, by ſowing the ſeeds upon a gentle hot-bed in the ſpring, and afterwards treating the plants in the ſame manner as the Marvel of Peru and other hardier kinds of annuals; tranſplanting them into the full ground the latter end of may. They will flower in july; and if ſome of the plants be placed in a glaſs-caſe, they will produce ripe ſeeds in autumn.

The ſixth and ſeventh require to be kept in a ſtove, being more tender than the reſt.

The eighth, in a favourable ſeaſon, will riſe in the ſpring from ſcattered ſeeds; and, if the ſummer prove warm, it will flower, and even perfect its ſeeds.

DESCRIPTIONS, *&c.*

1. The common Carrot, in its wild ſtate, has a ſlender, hard, whitiſh or browniſh fuſiform root. Stem upright, grooved, hiſpid, two feet high, with alternate branches, which are long (commonly from ſix or ſeven to nine or ten inches), have one leaf on them, except the primary or terminating one, which is naked, and have a ſingle umbel of flowers at top. Bottom and principal leaves ſheathing, tripinnate, the laſt pinnule toothed, and terminated by ſpinules, the nerves hiſpid. Univerſal involucre of the umbel pinnate, compoſed uſually of five, ſometimes only three long, linear leaflets; they are almoſt as long as the umbel, eight or ten in number and permanent: partial involucre, the outer trifid, longer than the umbellet, the inner ones ſimple. The univerſal umbel has ſometimes from thirty to forty unequal rays, the middle rays being very ſhort, the outer ones above an inch long: the partial umbel has fewer rays, but they alſo amount ſometimes to more than thirty, and are more equal than the others. The flowers are white, thoſe in the middle ſometimes tinged with purple; theſe are fertile, but thoſe in the circumference, which are irregular and larger than the others, are frequently either neuter or have piſtils only. The fruit is ſpheroidal, compoſed of two plano-convex ſeeds, on the back of which are four membranaceous narrow creſts, pectinated with linear-ſetaceous, innocuous, flexible teeth; and between theſe, three raiſed nerves, having very minute prickles on them along each ſide, bowing outwards: the belly is flat, or ſlightly concave, marked with obſcure longitudinal ſtreaks*.

The wild Carrot is common in paſtures, on balks and headlands. It is a biennial plant, flowering from june to auguſt.

The umbel is at firſt a little convex, but becomes gradually flat, and then as the flowers are going off, more and more concave, till it forms a perfect baſin, in its ſeeding ſtate reſembling a bird's-neſt. It is then eaſily diſtinguiſhed from other umbellate plants, and has derived its common Engliſh name from this circumſtance. Others, it is ſaid, call it *Bee's-neſt*, and that name is recorded by Johnſon, in his edition of Gerarde's herbal.

Carrot ſeeds have been recommended as a powerful diuretic, and an infuſion of them has been found to give relief in fits of the gravel and ſtone.]

* Gærtner.

Mr. Miller informs us, that the ſhops are ſupplied with old ſeeds of the garden Carrot, inſtead of freſh ſeeds of the wild plant. [This is one of the many ways by which efficacious medicines are brought into diſrepute; but if wild Carrot ſeeds be really valuable in calculous caſes, they may eaſily be gathered freſh by every one for himſelf.

Moles are ſo fond of the roots, that they are a proper bait to take theſe animals; but garden Carrots anſwer beſt for this purpoſe, as well as for deſtroying crickets, being made into a paſte with powdered Arſenic and Wheat meal; and for poultices to mitigate the pain, and abate the ſtench of foul and cancerous ulcers [a].

The ladies of this poliſhed age will ſmile at the ſimplicity of ancient times, when they are told, that the autumnal beauty of Carrot leaves allured many gentlewomen formerly, oftentimes to ſtick them in their hats or heads, or pin them on their arms inſtead of feathers [b].

Mr. Ray obſerved a variety of the wild Carrot on the ſea ſhore near Dover, with leaves of a dark green and gloſſy colour [c]. Dr. Stokes adds, that in a ſpecimen from the coaſt of Cornwall the leaflets are remarkably broad, and but ſlightly cut [d].

β, γ. The Garden Carrot is three feet high in its flowering ſtate; it differs however little from the wild one, except in the largeneſs and ſucculency of the plant, and particularly of the root, which with its ſuperior ſize uſually takes a tincture of yellow in different ſhades to deep orange, and becomes of a ſofter texture, without any of that acrimony and aromatic flavour which are found in the wild root. In Japan, where it is much cultivated, the root is of a colour very little inclined to yellow [e].]

Mr. Miller informs us, that he cultivated the wild carrot for many years, but could never get the ſeeds which were ſown in the ſpring to grow, but that part of the ſeeds which he ſowed in autumn came up well: theſe plants he treated in the ſame manner as the Garden Carrot, but could not improve the roots in the leaſt, for they continued to be ſmall, ſticky, and of a hot biting taſte. [In this and the like caſes he concludes, that the plants are ſpecifically different. This concluſion, however, is not to be admitted: for the improvement has probably been the effect of accident, or of time and care in a warmer climate; and the cultivated plants, if left to themſelves in a dry undunged ſoil, would probably relapſe into their primitive ſtate.]

Of Garden Carrots there are ſeveral varieties differing in the colour of their roots, as white, yellow, orange, and dark red or purple. Theſe variations may be continued, by taking care not to mix them together in the ſame garden. The Orange Carrot is generally moſt eſteemed in London. Mr. Miller takes the red or purple Carrot to be a diſtinct ſort: it is much more tender than the others, inſomuch that the roots were all deſtroyed by the firſt froſts in autumn. The ſeeds were ſent him from Aleppo. The roots were not ſo large as common Carrots, and were of a purple colour, very like that of a deep-coloured Radiſh; they were very tender and ſweet; the leaves were finer cut than thoſe of the common Carrot, and leſs hairy.

2. This has a channelled ſtalk near three feet high, terminated by large umbels. The ſegments of the lower leaves are cut into other obtuſe ſegments, and are of a deep green colour.

[It much reſembles the common Carrot. The whole ſtem is hiſpid. The involucre is ſhorter than the umbel, and quinquifid-pinnate: the involucels are three-toothed. The corolla is ſubradiate, with white petals, bent in and cloven [f]. In the centre there is a ſmall barren flower. The ſeeds are hiſpid [g].

It is a biennial plant; native of Italy, Spain, and Barbary; and was cultivated in 1768, by Mr. Miller. It flowers in june and july [h].]

3. This is an annual plant, with an upright, ſmooth, channelled ſtalk, three feet high. Leaves ſmooth, divided into many fine narrow ſegments, like thoſe of Fennel. The ſtalks branch towards the top, and each branch is terminated by a large umbel, compoſed of a great number of ſmall ones. The involucre is ſhorter than the umbel, and each of the leaves which compoſe it is trifid.

[The baſe of the umbel is a ſolid, roundiſh, common receptacle. Involucre, as it were one-leafed at the baſe, is, however, many-leaved, united with the receptacle, and has trifid leaflets. Involucels many-leaved, ſimple. Umbellules very numerous. Flowers equal, perfect. Petals bent in, two-lobed, white. Anthers purpliſh. Proper receptacles purpliſh-brown. Fruit tranſverſely compreſſed, oblong, ſtriated, even [i].]

The rays which ſuſtain the umbellules being long and ſtiff, are uſed by the Spaniards, &c. for picking their teeth. [When they have ſerved this purpoſe, they are chewed, and thus are ſuppoſed to be of ſervice in cleanſing and faſtening the gums: however this may be, they leave a pleaſant aromatic taſte in the mouth [k].

Native of the South of Europe, Barbary, and mount Libanus. It was cultivated in 1597 by Gerarde, and flowers from june to auguſt [l].]

4. This is an annual plant, with ſmoother ſtalks than the common Carrot; the ſegments of the leaves are broader, and of a lucid green; the umbels are larger, and not ſo regular.

[Native of the South of France. Cultivated in 1722, in the Chelſea garden. It flowers in june and july [m].]

5. This riſes with an upright ſtalk above two feet high. Leaves bipinnate, hairy. The ſtalk branches at top into ſeveral diviſions, each terminated by an umbel of white flowers: [they are radiated, and the ray is ſmall. Involucre with pinnate leaves: involucels with undivided leaves. Fruits five or ſeven. Seeds with compreſſed prickles in a triple row, and barbed at the end. Native of Barbary [n]. Cultivated here in 1699 [o].

β. The maritime variety is low and hirſute, with the ſtems almoſt leafleſs, and the germs hirſute [p].

Linnæus, thinking that perhaps theſe differences might ariſe from ſoil and ſituation, has given it only as a variety. Gouan, however, has ſhown it to be very different; and Krocker deſcribes it as very much reſembling the common Carrot, but ſmaller in the ſtem, leaves and involucres. The umbel is alſo ſmaller, and contracts as it advances to ripeneſs: the florets are not radiated, three or four of them are fertile, and the reſt are barren, and white in one umbel: the ſeeds have four longitudinal creſts, very much toothed; before they are ripe they are beſet with red barbs. He doubts, however, whether it may not be a variety of the common Carrot. It is annual, and flowers in july and auguſt.

Gærtner has no doubt but that it ought to be removed from this genus into that of Caucalis.

Native of the South of France, on the coaſt of the Mediterranean.

6. This has the ſtature of common Carrot; but the ſtem has ſtiffer ſtrigæ on it, and is not merely rugged. The leaves are groſſer, even and ſhining, as are alſo the petiolæ. It is biennial, and a native of Barbary [q].

7. The whole ſtem is rough with hairs. Leaves from a green ſheath not emarginate. Branches rough. Stem three feet high, with alternate branches, and an umbel terminating it. Leaves lucid, flat above, roughiſh underneath: leaflets pinnatifid, with two or three pairs of awned ſegments. Umbellets equal. Leaves of the univerſal involucre

twice trifid, with a flat membranaceous petiole; partial deeply trifid. Seeds as in the common ſort, but larger. It is a biennial plant, and a native of the county of Nice'.]

PROPAGATION AND CULTURE.

In the Garden.

1. The Carrot is commonly cultivated in gardens for the kitchen, and the different varieties of it are, in ſome places, eſteemed, though in London, the Orange Carrot is preferred to all the other.

They are propagated at two or three different ſeaſons, or ſometimes oftener, where people are fond of young Carrots. The firſt ſeaſon for ſowing the ſeeds is ſoon after Chriſtmas, if the weather be open; this ſhould be in warm borders, near walls, pales, or hedges, but they ſhould not be ſown immediately cloſe thereto; but a border of Lettuce, or other young ſallad herbs, of about a foot wide, ſhould be next the wall, &c.; for if the Carrots were ſown cloſe to the wall, they would draw up weak, without making any tolerable roots.

Theſe delight in a warm ſandy ſoil, which is light, and ſhould be dug pretty deep, that the roots may the better run down; for if they meet with any obſtruction, they are very apt to grow forked, and ſhoot out lateral roots, eſpecially where the ground is too much dunged the ſame year that the ſeeds are ſown, which will alſo occaſion their being worm-eaten; it is therefore the better method to dung the ground intended for Carrots the year before they are ſown, that it may be conſumed, and mixed with the earth; but in ſuch places where there has not been ground ſo prepared the year before, and there may be a neceſſity for dunging it the ſame year as the Carrots are ſown, the dung ſhould be well rotted which is laid upon it, and ſhould be thinly ſpread over the ground; and in the digging of it into the ground, great care ſhould be taken to diſperſe it all through the ground, and not to bury it in heaps; for that will ſtop the roots of the Carrots in their downright growth, and cauſe them to be ſhort and forky. Where the ground is inclinable to bind, there cannot be too much care taken to break and divide the parts: therefore in digging the land for Carrots, there ſhould never be large ſpits taken, but they muſt be very thin, and the clods well broken; which, if not attended to by the maſter, is ſeldom properly performed by workmen, who are too apt to hurry over their work, if they are not well obſerved.

The ground when dug ſhould be laid level and even, otherwiſe when the ſeeds are ſown and the ground is raked over, part of the ſeeds will be buried too deep, and others will be in danger of being drawn up into heaps; ſo the plants will come up in bunches, and other parts of the ground be naked, which ſhould always be carefully avoided.

The ſeeds have a great quantity of ſmall forked hairs upon their borders, by which they cloſely adhere, ſo that they are difficult to ſow even, ſo as not to come up in patches; they ſhould therefore be rubbed well through both hands, whereby the ſeed will be ſeparated before it is ſown; then a calm day ſhould be choſen to ſow it in; for if the wind blows, it will be impoſſible to ſow it equal, for the ſeeds being very light, will be blown into heaps. When the ſeed is ſown, the ground ſhould be trod pretty cloſe with the feet, that it may be buried, and then the ground muſt be raked level.

When the plants are come up, and have got four leaves, the ground ſhould be hoed with a ſmall hoe about three inches wide, cutting down all young weeds, and ſeparating the plants to four inches diſtance each way, that they may get ſtrength; and in about a month or five weeks after, when the weeds begin to grow again, the ground ſhould be hoed over a ſecond time, in which you ſhould be careful not to leave two Carrots cloſe to each other, as alſo to ſeparate them to a greater diſtance, cutting down all weeds, and ſlightly ſtirring the ſurface of the ground in every place, the better to prevent young weeds from ſpringing, as alſo to facilitate the growth of the young Carrots.

In about a month or five weeks after, they muſt be hoed a third time, when you muſt clear the weeds as before; and now the Carrots ſhould be cut out to the diſtance they are to remain, which muſt be proportioned to the ſize you intend to have them grow. If they are to be drawn while young, five or ſix inches aſunder will be ſufficient, but if they are to grow large before they are pulled up, they ſhould be left eight or ten inches diſtant every way; you muſt alſo keep them clear from weeds, which, if ſuffered to grow amongſt the Carrots, will greatly prejudice them.

The ſecond ſeaſon for ſowing theſe ſeeds is in february, on warm banks, ſituated near the ſhelter of a wall, pale, or hedge; but thoſe which are intended for the open large quarters, ſhould not be ſown before the beginning of march, nor ſhould you ſow any later than the end of the ſame month: for thoſe which are ſown in april or may, will run up to ſeed before their roots have any bulk, eſpecially if the weather ſhould prove hot and dry.

In july you may ſow again for an autumnal crop, and at the end of auguſt you may ſow ſome to ſtand the winter; by which method you will have early Carrots in march, before the ſpring ſowing will be fit to draw; but theſe are ſeldom ſo well taſted, and are often very tough and ſticky. However, as young Carrots are generally expected early in the ſpring, moſt people ſow ſome at this ſeaſon; but theſe ſhould be ſown upon warm borders and dry land, otherwiſe they are ſeldom good. If the winter ſhould prove very ſevere, it will be proper to cover the young Carrots with Peaſe-haulm, the haulm of Aſparagus, or ſome ſuch light covering, to prevent the froſt from penetrating into the ground, which often deſtroys the Carrots, where this care is wanting: but if in very hard winters the Carrots ſhould be all deſtroyed which were ſown in autumn, there ſhould be a hot-bed made early in the ſpring to ſow ſome, which will be fit for uſe long before any that are ſown in the full ground; but theſe beds ſhould be earthed fifteen or ſixteen inches deep, that the roots may have a proper depth of ſoil to run down. If theſe beds are lined with hot dung twice, at ſuch times when the heat of the beds decline, it will greatly forward the growth of the Carrots, but there ſhould be great care taken not to draw the plants up too weak; theſe may be allowed to grow cloſer together than thoſe ſown in the full ground, becauſe they will be drawn for uſe very young. Many people mix ſeveral other ſorts of ſeeds, as Leek, Onion, Parſnep, Radiſh, &c. amongſt their Carrots; and others plant Beans, &c. but, in my opinion, neither of theſe methods are good; for, if there is a full crop of any one of theſe plants, there can be no room for any thing elſe amongſt them, ſo that what is got by one is loſt by another; and beſides, it is not only more ſightly, but better, for the plants of each kind to be ſown ſeparate; and alſo by this means your ground will be clear, when the crop is gone, to ſow or plant any thing elſe; but when three or four kinds are mixed together, the ground is ſeldom at liberty before the ſucceeding ſpring: beſides, where Beans, or any other tall-growing plants are planted amongſt the Carrots, they are apt to make them grow more in top than root; ſo that they will not be half ſo large as if ſown ſingly, without any other plants amongſt them.

The covetouſneſs of ſome gardeners will not permit them to cut out their Carrots to a proper diſtance when they hoe them, ſo that by leaving them cloſe, they draw each other up weak: and if they are drawn while young, they never recover their ſtrength afterward ſo perfectly, as to grow near the ſize of thoſe which are properly thinned at the firſt hoeing; therefore where the Carrots are deſigned to have large roots, they muſt never ſtand too cloſe, nor ſhould they have any other crop mixed with them.

' Allioni.

In the Field.

This root has been long cultivated in gardens for the table, but has not till of late years been cultivated in the fields for cattle, nor has it been practiſed as yet but in few parts of England; it is greatly to be wiſhed, that the culture of it was extended to every part of England, where the ſoil is proper for the purpoſe; for there is ſcarce any root yet known, which more deſerves it, being a very hearty good food for moſt ſorts of animals. One acre of Carrots, if well planted, will fatten a greater number of ſheep or bullocks, than three acres of Turneps, and the fleſh of theſe animals will be firmer and better taſted. Horſes are extremely fond of theſe roots, and for hogs there is not any better food. I have alſo known theſe roots cultivated for feeding of deer in parks, which has proved of excellent uſe in hard winters, when there has been a ſcarcity of other food; at which times great numbers of deer have periſhed for want, and thoſe which have eſcaped, have been ſo much reduced, as not to recover their fleſh the following ſummer; whereas, thoſe fed with Carrots have been kept in good condition all the winter, and upon the growth of the graſs in the ſpring, have been fat early in the ſeaſon, which is an advantage, where the graſs is generally backward in its growth.

There is alſo an advantage in the cultivation of this root beyond that of the Turnep, becauſe the crop is not ſo liable to fail; for as the Carrots are ſown in the ſpring, the plants generally come up well, and unleſs the months of june and july prove very bad, there is no danger of the crop ſucceeding: whereas Turneps are frequently deſtroyed by the flies at their firſt coming up, and in dry autumns they are attacked by caterpillars, which in a ſhort time devour whole fields, but Carrots are not attacked by theſe vermin: therefore every farmer who has a ſtock of cattle or ſheep, ſhould always have a ſupply of theſe roots, if he has land proper for the purpoſe, which muſt be light, and of a proper depth to admit of the roots running down.

In preparing the land for Carrots, if it has not been in tillage before, it ſhould be ploughed early in autumn, and then ploughed acroſs again before winter, laying it up in high ridges to mellow by the froſt; and if the ground is poor, there ſhould be ſome rotten dung ſpread over it in winter, which ſhould be ploughed in about the beginning of february; then in march, the ground ſhould be ploughed again to receive the ſeeds; in the doing of which, ſome farmers have two ploughs, one following the other in the ſame furrow, ſo that the ground is looſened a foot and a half deep. Others have men with ſpades following the plough in the furrows, turning up a ſpit of earth from the bottom, which they lay upon the top, levelling it ſmooth, and breaking the clods; the latter method is attended with a little more expence, but is much to be preferred to the firſt, becauſe in this way the clods are more broken, and the ſurface of the ground is laid much evener.

If the land has been in tillage before, it will require but three ploughings; the firſt juſt before winter, when it ſhould be laid in high ridges for the reaſons before given; the ſecond croſs ploughing ſhould be in february, after which, if it is well harrowed to break the clods, it will be of great ſervice; the laſt time muſt be in march to receive the ſeeds; this ſhould be performed in the manner before mentioned. After this third ploughing, if there remain great clods of earth unbroken, it will be proper to harrow it well before the ſeeds are ſown. One pound and a half of ſeeds will be ſufficient for an acre of land; but as they are apt to adhere together, it renders them more difficult to ſow even than moſt other ſorts; therefore ſome mix a quantity of dry ſand with their ſeeds, rubbing them well together, ſo as to ſeparate the Carrot ſeeds from each other, which is a good method. After the ſeeds are ſown, they muſt be gently harrowed in to bury them; and when the plants come up, they ſhould be hoed in the manner before directed.

In order to preſerve Carrots for uſe all the winter and ſpring, they ſhould be dug up about the beginning of november, when the green leaves are decayed, and laid in ſand in a dry place, where the froſt cannot come to them.

If any are to be ſaved for ſeed, reſerve ſome of the longeſt and ſtraighteſt roots; plant them the middle of february in a light ſoil, about a foot aſunder each way; and about the middle of auguſt, when the ſeeds are ripe, cut off the ſtalks, expoſe them to the ſun and air for ſeveral days in a dry place, beat out the ſeeds, put it up in bags, and keep it in a dry place until you uſe it. This ſeed is ſeldom eſteemed good after the firſt or ſecond year at moſt; but new ſeed is always preferred, nor will it grow when it is more than two years old.

[The field culture of Carrots is beſt carried on in a tract of Suffolk, called from the nature of its ſoil the *Sandlings*; it is a triangle with Woodbridge, Bawdſey cliff and Orford: the three angles. They ſow five pounds of ſeed to the acre on a double furrow about fourteen inches deep. The time of ſowing is about Lady-day; and they begin to hoe at Whitſuntide. They give three hoeings in all, which coſt from fifteen to eighteen ſhillings an acre, ſometimes more. Ten loads, of forty buſhels each, topped clean, on an acre, in good land, is reckoned to be a middling crop. They feed with them from before Chriſtmas, and continue ſometimes till Whitſuntide: taking them up and houſing them in the latter part of the ſeaſon, to have the land clear for barley ſowing[1].

The time of ſowing among the Sandy field gardeners is the firſt week in march; others ſow in the middle, and others again at the end of march: but the time muſt be regulated in ſome meaſure by the ſeaſon, and the convenience of the farmer. The time of ſowing is by ſome extended from the beginning of february to the end of april, but this is too wide a range, if it can be avoided. New ſeed will come up a week ſooner than that which is old; and the crop depends very much upon having good ſeed. Mr. Miller recommends only a pound and half of ſeed to be ſown on an acre; but this is certainly too little. On the Sandlings we have ſeen that they have ſown five pounds; others ſow eight, ten, and even twelve pounds, which is in general waſting ſeed.

The common rule for the firſt hoeing is ſeven weeks after the ſeed is ſown, or in general the beginning or middle of may; the ſecond the middle of june; ſomewhat ſooner or later, according to the ſtate of the crop.

The uſual produce on poor lands is 200, and on good land 400 buſhels. We have had accounts of 250, 300, 312, 326, 340, 352, 368, 400, 460, 482, and even 640 and 700 buſhels produced from an acre; but let the huſbandman always beware of calculating on great crops, which are commonly produced on a ſmall ſcale, or on very rich land, or by extraordinary tillage and manuring, or by ſome unforeſeen fortunate circumſtances.

For preſerving Carrots during winter ſeveral methods are preſcribed. Soon after michaelmas, in dry weather, they may be taken up with a common dung-fork, and piled up or ſtacked in a corner of the field, in the following manner. Lay a platform of earth ſix inches above the level, two feet and a half wide, and of a length proportioned to the quantity of the crop, ſuppoſe from ten to twenty yards. On this earth ſcatter a ſlight layer of ſtraw. On this place a row of carrots, with their tops on and turned outwards; the tails lapping over one another, ſo that the width covered with carrots is about two feet. Top the ſmall roots, and lay them in the middle croſswiſe, to keep the two ſides from parting, by preſſing the weight more on the centre. On every two or three rows ſcatter a little ſtraw, and thus continue to build up about four feet high;

[1] Young's tour. 2. 123.

then

then cover the tops carefully with dry ſtraw, and lay ſome ſedge or other coarſe material over all, by way of thatch. Then begin another line, parallel to the firſt, juſt leaving room to paſs between them; and ſo continue till the whole crop is taken up. Fill the alleys with dry ſtraw, and guard the outſide with bundles of ſtraw ſtaked down, or ſet faſt with hurdles, to prevent the wind from removing the ſtraw and covering [s].

Others, having taken them up in dry days in october, put them directly into ſmall upright cocks of ten buſhels each, entirely covered, with the tops cut off; and being thus dried, carry them into a barn or ſhed, throwing ſome ſtraw over them, but taking care not to pack them too cloſe [t].

Or they may be left in the cocks, well covered over with ſtraw or fern till they are quite dry, and then protected with earth, beat ſmooth with a ſpade [u]. Some twiſt off the tops with the hand; and others take off half an inch of the roots to prevent them from ſprouting: but theſe attentions can only be beſtowed on ſmall crops.

If they are bartelled up with very dry ſand, after being previouſly well dried, they may be preſerved a conſiderable time at ſea.

In the Sandlings the practice is to take up the Carrots as they are wanted, only keeping a ſtore beforehand in caſe of froſt: thus, however, in ſome years many rot on the ground [x].

Long experience has now confirmed what Mr. Miller aſſerts, that Carrots are a hearty food for ſheep, cattle, horſes, hogs and deer, particularly for horſes; they may alſo be applied to feeding hounds and pointers when boiled, and mixed with milk and barley meal.

Carrots are alſo an excellent preparation for barley, in ſands and ſandy loams, that are not foul with quich or ſpear-graſs; for in ſuch lands the hoeing for Carrots increaſes rather than deſtroys the quich, by hacking it in pieces. No crop can be better for ſuch lands, when clean, than Carrots; becauſe it admits no ſummer ploughing whatever, and it is put in on one earth given with a trench-plough in march; ſo that as much tenacity is given to theſe naturally looſe ſoils as poſſible. The crop may be left late in the ground, and if the ſoil be very ſandy, a crop of buck-wheat may follow, for which any degree of cleaning from quich may be given, if neceſſary [y].

Mr. Miller's directions for ploughing are ſuitable to ſtiff land, which is not ſuitable to Carrots.

A very good ſpirit may alſo be diſtilled from Carrots; and the refuſe will be excellent for feeding hogs. One ton eight ſtone, after being expoſed a few days to dry, weighed 160 ſtone, and meaſured forty-two buſhels. After being waſhed, topped and tailed, they loſt in weight eleven ſtone, in meaſure ſeven buſhels. From this quantity fifty gallons were drawn off; theſe were rectified, and twelve gallons of unexceptionable ſpirit were obtained. The refuſe weighed forty-eight ſtone, and the waſh from the ſtill meaſured 112 gallons. So that the refuſe greatly exceeds that of an acre of barley. And an acre of Carrots, allowing the produce to be twenty tons, will produce 240 gallons of ſpirit; which is conſiderably more than can be obtained from five quarters of barley [z]. But the produce of an acre ought not to be laid at more than from ten to fourteen tons [a]; and therefore the quantity of ſpirit from an acre of Carrots will not exceed 168 gallons.

Carrots have ſome advantages over Turneps, beſides the principal one already mentioned of their being better adapted to the ſort of ſoil which beſt ſuits them both. For they are leſs liable to be damaged by froſt: they are not ſubject to the ſame diſtempers and accidents; and they laſt till april, the ſeaſon of great difficulty, when farmers frequently know not what to provide for their ſtock, eſpecially ſheep [b]. Being alſo a ſpring crop, if the plant miſſes, the ſeed only is loſt, and the land is in perfect order for turneps at midſummer: or if it be only a ſcattered plant, the intervals may be filled by ſowing turneps, or planting cabbages [c].

Carrot ſeed has been for many years raiſed at Wethersfield in Eſſex, perhaps becauſe it poſſeſſes two ſoils beſt adapted to this culture; rich ſand to raiſe the carrots the firſt year, and ſtrong loam for the year of ſeeding. The preparation of the ſoil conſiſts in making it very fine by repeated ploughings and harrowings, uſually three or four earths are given; and the ſeed, twenty pounds an acre, apparently an unneceſſary quantity, ſown in april. They hand-hoe twice, ſetting the plants out ſeven inches aſunder. At michaelmas they dig up, cut off the tops to the length of an inch, and pack up the roots in barns with ſtraw, taking care that they are dry enough when laid up: ſecuring them is a work of ſome difficulty, for air muſt have acceſs to them, and yet froſt muſt be excluded. The crops are large; a good produce is three buſhels on a rod, but four have been known. For re-planting in the ſpring, they chooſe a piece of freſh land, if there be any on the farm; if not, ſuch as is in good heart, but they never manure it. The preparation is to throw two three feet ridges together; in a dry ſeaſon, in febriary or march, they cut the tap end of the carrots off, to the amount of one third of the root, and plant a double row upon each ridge at three feet between the plants, and two feet row from row, in a quincunx order, ſo that the plants of one row may be againſt the ſpaces of the other. They are twice hoed, and twice earthed up, the ſecond time very high. The heads are cut off when quite dry, as they ripen, by women, and being laid on pack cloths, are threſhed and dreſſed by men [d].

Carrots may be cultivated with ſucceſs in young plantations of trees, where the ſoil is proper for them. In taking up the carrots, leſs damage is done to the young ſtems of the trees than by digging between them, all the good effects of ſtirring the ground are produced, and a profitable crop is gained [e].

Mr. Miller affirms that this root has not till of late years been cultivated in the fields for cattle. It appears from Norden's Surveyor's Dialogue, publiſhed in 1600, that carrots were commonly cultivated about Orford in Suffolk, and about Norwich in Norfolk [f]. They were alſo introduced very early from Flanders into Kent, about Sandwich, and other places. Gerarde, in 1597, ſays that they were ſown in the fields. Neither of theſe authors, however, mentions that they were uſed for feeding cattle: they were probably cultivated chiefly for the London market. Worlidge and Mortimer ſay, that they are good for hogs and geeſe.

2, 3, &c. Of the other ſorts of Daucus it is enough to ſay, that the ſeeds ſhould be ſown in autumn, for thoſe which are ſown in the ſpring frequently fail, or at leaſt remain in the ground till next year before they grow; the plants require no other culture but to keep them clean from weeds, and to thin them where they are too cloſe.

DESCRIPTION, *&c.*

A tree, with ſcabrous leaves, reſembling thoſe of Beech. Flowers peduncled, looſely panicled, both axillary and terminating [1]. Fruit a coriaceous, ſwelling capſule, ending in an incurved beak, very ſmooth, of a yellow bay colour, opening on one ſide only by a longitudinal cleft. Seeds two, globular, crooked next the baſe, berried, red, becoming blackiſh when ripe, fixed to the bottom of the capſule; their aril is incomplete, ſpongy-membranaceous, ſnow-white, torn at the edge, ſcarcely covering the lower half of the ſeed [2].

The leaves being very thick and rugged, are uſed by the inhabitants of Ceylon, where it grows naturally, in poliſhing. Hence they name it *Kaſtuiriel* or *Karoſſawael*, from *Karoſſa*, to ſmooth or poliſh [3].

DELPHINIUM. (Δελφινιον *Diſſect. from a fancied reſemblance of the flower, before it opens, to a dolphin. —Conſolida, from its conſolidating qualities.*)

Nectaries four-leaved ſhorter than the petal; leaves palmate with three lobes obtuſe.

DESCRIPTIONS, &c.

[Theſe are moſtly ſpecious hardy annuals or perennials. The lower leaves digitate or palmate; the upper leſs divided, and ſometimes even entire. The flowers are in looſe ſpikes or panicles at the ends of the ſtem and branches, of various colours, but chiefly blue; never yellow.

1. Root annual. Stalk upright, a foot high or more, round, pubeſcent, divided into alternate diverging branches. Leaves alternate, the lower on petiols near half an inch long, the upper ſeſſile or nearly ſo; they are divided down to the baſe into three or five parts, which are deeply cut into ſlender linear ſegments, often forked at the end. Pedunckes one-flowered, from the ends of the ſtalk and branches, having on them a few entire, awl-ſhaped leaves. Corolla blue, varying to purple, pink, and white, and in gardens to ſtriped, and many different ſhades of colour: petals irregularly ſcalloped on the edge; the lateral ones broadeſt, the uppermoſt lanceolate, not blunter than the reſt, rather ſhorter than the nectary, but projecting backwards into a conical tube. Stamens about ſeventeen: anthers roundiſh, double. It has frequently two ſtyles, and ſometimes only one. Capſules or ſiliques yellowiſh-brown, ſmooth, with nine or ten black ſhining ſeeds in them, placed in a double row, and rough with ſhort hairs and very ſmall tubercles[a].

In Engliſh it is called Wild or Corn Lark's-ſpur, Lark's-claw, and Lark's-toes. In French, *Pied d'Alouette*. In German, *Ritterſporn*. In Daniſh and Swediſh, *Ridderſpore*. In Italian *Speronella*. In Spaniſh, *Eſpuela de caballero*.

It grows wild in corn fields in Sweden, Denmark, Germany, France, Switzerland, Carniola, Italy, and Spain. It was not obſerved in a wild ſtate in Britain by Gerarde; and his editor Johnſon (an° 1636) expreſly ſays, not with us, that I have yet obſerved. Parkinſon however, in his Paradiſus, publiſhed ſeven years ſooner, affirms, that the leſſer wild kind is found in ſome fields of our own country; but he does not ſay that he had ſeen it. James Sherard, M. D. obſerved it in Swaffham field in Cambridgeſhire. Profeſſor John Martyn found it there, and in other fields of the ſame county about the year 1730; and I have remarked it abundantly, not only with blue, but with pink, purple, and white flowers, in moſt of the open fields round Cambridge, ever ſince the year 1752.

The expreſſed juice of the petals, with the addition of a little alum, makes a good blue ink. The ſeeds are acrid and poiſonous[b].

2. The ſtalk of the upright or garden Larkſpur is eighteen inches and more in height, and ſeldom branched. Leaves finely divided, commonly by threes, on broad petiols; ſegments linear, quite entire, channelled above. Spike of flowers erect and more denſe than the preceding. Commonly only one capſule or ſilique[c]. This affords a great variety of colours, in the flowers, both ſingle and double, ſome very large and numerous in cloſe ſpikes, making a fine appearance from the end of june to auguſt.

The original country of this is unknown. It now comes up ſpontaneouſly in ſeveral parts of Europe, but probably from garden ſeeds. Linneus and others are of opinion that the Larkſpur is the Hyacinth of the poets. Profeſſor John Martyn however, after profoundly conſidering the matter, determines it to be the *Lilium Martagon*; and the learned Heyne acquieſces in his opinion. There does not appear to me to be the leaſt foundation for Linneus's notion.

3. Stature the ſame as in the firſt or fifth ſpecies, with corollas of Aconite. Stem a foot high, paniculed, branching, hoary, pubeſcent. Leaves pedate-multifid, linear, becoming hoary: the upper ones only three-parted. Flowers terminating, ſolitary, peduncled, ſmall, livid, variegated within with purple and green. Outer nectary tubular, longer than the petals, very obtuſe at the end, elongated at the baſe, ſo that the anterior horizontal lip is placed in the middle. The inner nectary embraces the ſtamens on both ſides with an obtuſe lobe, but in front and above it has four teeth nearly equal and marked on the edge with a purpliſh line: the tip is very obtuſe and thick, and is bent back with a contracted neck; the four lower petals are ovate-lanceolate, equal, greeniſh but purpliſh on the ſides. Stamens the length of the petals, purpliſh.

Native of the Dardanelles. Annual[d].

4. Stature of the ſecond ſort, but more hoary. Branches divaricating in a ſimple ſtem. Corollas blue with a green outſide. Nectary cloven with acutiſh lobes; ſpur having frequently two teeth at the tip.—It differs from the monogynous ſpecies in

[a] Pollich. [b] Withering, Relhan. [c] Withering. [d] Haller.
[e] Linn. mant.

the number of the capſules; from the trigynous ſpecies in having the inner nectary one-leafed, or the inner ſpur not two-parted; therefore theſe cannot be ſeparated from the genus of Staphiſagria. The piſtils are either one or three in the ſame plant, ſo that the number of theſe is hardly conſtant.—Native of Barbary [a].

Stalk three feet high or more and very branching; the branches come out horizontally at firſt, but afterwards turn up ſo as to make an acute angle with the ſtalk; the leaves are long and finely divided: the flowers are placed thinner in the ſpikes than thoſe of the upright ſort, are large, and ſome of them very double and of various colours. This comes later to flower than the upright Larkſpur.

5. This has a very branching ſtalk, about two feet high. The lower leaves are divided into many broad obtuſe ſegments, but thoſe which are upon the ſtalks are generally ſingle; the flowers grow ſcatteringly towards the upper part of the branches, are ſmall, and of a deep blue colour; they are ſucceeded by very ſmall ſeed-veſſels, which are ſingle or double, rarely three together.

[Stem ſimple, with wand-like, naked, ſtiff branches. Leaves like thoſe of the ſecond ſort. Bractes ſubulate. The corolla, beſides the nectaries or four lower petals, has two roundiſh lateral petals, fixed by long claws, and bent down towards the outer or loweſt petals and lying on them. The nectaries have no deflex lips [b].

Native of the South of Europe and the Levant. Cultivated in 1731, by Mr. Miller [c], who had the ſeeds from Gibraltar.

6. This has a perennial root, which puts out two or three branching ſtalks every ſpring, which riſe about a foot and a half high. Leaves ſmooth and of a light green colour above, and hoary beneath, compoſed of many narrow ſegments, which terminate in ſeveral acute points. The flowers come out towards the upper part of the ſtalks ſingly, each on a long naked peduncle; they are large, and of a fine azure colour. They appear in june and july, and the ſeeds ripen in autumn.

[Capſules hoary [d].—Native of Siberia. Cultivated in 1758, by Mr. Miller [e],] who had the ſeeds from Dr. Ammann, of Peterſburgh.

7. [Root perennial, with annual ſtems growing to the height of ſix or ſeven feet. Leaves broad, divided into five or ſeven parts, cut into many narrow ſegments towards the top, they are alternate from the joints on long footſtalks, ſo that they hang down. Flowers in long ſpikes at the extremities of the ſtalks. Corollas of a fine blue colour [f].

Mr. Miller had firſt ſet this down as an American plant. Afterwards he informs us that the ſeeds were ſent him from Peterſburgh by the late Dr. Ammann: he therefore ſuppoſes it to be a native of Siberia or Tartary: it turns out however to be a native of Silefia. It ſeems to be the variety of *D. elatum* mentioned by Krocker.

* Cultivated 1756, by Mr. Miller [f].

8. Height of a man. Root perennial. Leaves ſlightly villoſe, becoming ſmooth by age, half-five-lobed, petioled; lobes acute, often half-three-lobed, ſharply ſerrate. Spike of flowers very long and handſome; peduncles one-flowered, lanuginoſe; corollas deep blue, with a wrinkled ſpur [g].

Native of Switzerland and Siberia. Cultivated 1656, by Mr. John Tradeſcant, junior. Flowers from june to ſeptember [h].

9. Root perennial. Stem upright, five or ſix feet high, branching. Lower leaves large, divided into three lobes to the petiole, and theſe cut on their borders into acute ſegments: they are a little hairy, and of a grayiſh colour, ſtanding upon pretty long petioles. Stem-leaves ſmaller, and not ſo deeply divided. The principal ſtalk is terminated by a long looſe ſpike of flowers, which is often a foot and a half long. The ſmall ſide-branches, which grow erect, have ſmaller ſpikes. The flowers are not much larger than thoſe of the common Larkſpur, and are of a pale blue colour. The bearded nectary has, at firſt ſight, the appearance of a large fly in the tube of the flower.—If ſowed at the end of june, or beginning of july, and in cool ſeaſons there is frequently a ſucceſſion of flowers till the end of auguſt. The ſeeds were ſent to Mr. Miller by Mr. John Bartram (about 1758) from Philadelphia; but it grows naturally in moſt parts of North America, where it occaſions great diſorders in the cattle that feed upon the leaves [i].

This approaches very near to *D. urceolatum*, *Jacqu. ic. collect.* 1. 153. but it differs in having the leaves ſmooth and flat; the ſtem ſmooth and purple [k].

10. This differs from all the other ſorts in the duſky red colour of the flowers as in *Veratrum nigrum*.—It is very like *D. elatum* in every thing, except that the ſtem, petioles and peduncles are pubeſcent, the petals equal, the whole corolla more regular, the lips deeply parted and ſtraight, the horn ſtraight, even, and the length of the pedicels; no ſubulate bracte on each ſide the baſe of the corolla [l].

It is a perennial plant [m].—Found in Siberia, by Pallas. Introduced 1785, by William Pitcairn, M. D. [n]

11. This is an annual plant, riſing with a ſtrong hairy ſtalk about two feet high. Leaves hairy, compoſed of five or ſeven oblong lobes, which have frequently one or two acute indentures on their ſides. The flowers form a looſe ſpike at the upper part of the ſtalk, each on a ſhort peduncle. They are of a pale blue or purple colour.

[Linnæus obſerves, that the lobes of the leaves are trifid. Horn of the nectary very ſhort and obtuſe.

A variety with leaves veined with white, differs in having the leaf gaſhed, ſeven-parted, the diviſions acuminate, the horn or ſpur of the corolla not obſcure, but the length of the pedicel [o].

Native of the South of Europe. Cultivated in 1596, by Gerarde. It flowers from april to auguſt; and is biennial [p].]

The common people uſe the powder of the ſeed to kill lice, whence it is named Louſewort.

PROPAGATION AND CULTURE.

1—5. The annual ſorts are propagated by ſeeds, which ſhould be ſown where the plants are deſigned to remain, for they do not bear tranſplanting well, eſpecially if they are not removed very young: thoſe ſeeds which are ſown in autumn, produce the ſtrongeſt plants and moſt double flowers, and ripen their ſeeds better than thoſe which are ſown in the ſpring, as they come earlier to flower; but to continue a ſucceſſion of theſe flowers, there ſhould be ſome ſeeds ſown in the ſpring. When they are ſown on the borders of the flower-garden for ornament, they ſhould be in patches of about a foot diameter, in the middle of the borders at proper diſtances; in each of theſe patches may be ſcattered ten or a dozen ſeeds, covering them over about a quarter of an inch with earth; and in the ſpring the plants may be thinned, leaving about five or ſix of the upright ſort in each patch to ſtand for flowering; but of the branching ſort, not more than three or four, becauſe theſe require room; after this the plants will require no farther care but to keep them clean from weeds, and when they begin to flower ſhould be ſupported by flower-ſticks to prevent their being broken by wind, eſpecially if they are not in a ſheltered ſituation. If the ſeeds were well choſen, there will be very few ordinary flowers among them; and if there are ſeeds of the different coloured flowers ſown in each patch, they will make a pleaſing variety: but the upright ſort ſhould never be mixed in the ſame patches with the branching, becauſe they do not flower at the ſame time.

[a] Linn. ſpec. [b] Ibid. [c] Hort. kew. [d] Linn. ſpec. [e] Hort. kew. [f] Mill. ic. [g] Hort. kew. [h] Haller. [i] Hort. kew. [k] Miller's figures. [l] Hort. kew. [m] Linn. ſuppl. [n] Retz. [o] Hort. kew. [p] Linn. ſyſt. [q] Hort. kew.

But in order to preſerve the two ſorts ſine without degenerating to ſingle or bad colours, there ſhould be a bed of each ſort ſown in autumn, in ſome ſeparate part of the garden, where the plants ſhould be properly thinned, and kept clean from weeds, till they begin to ſhew their flowers; when they ſhould be carefully looked over every other day, to pull out all thoſe plants, whoſe flowers are not very double nor of good colours; for if theſe are permitted to ſtand among the others till their farina has impregnated them, it will certainly cauſe them to degenerate; ſo that thoſe perſons who are contented with only marking their good flowers for ſeed, and ſuffer the others to ſtand for ſeed among them, will always find themſelves diſappointed in the goodneſs of their flowers the following ſeaſon: therefore thoſe who propoſe to have theſe flowers in perfection, ſhould never gather the ſeeds of ſuch as grew in the borders of the flower-garden; becauſe there it will be almoſt impoſſible to preſerve them ſo true, as when they are in beds at a diſtance from all other kinds.

When the ſeed-veſſels turn brown, they muſt be carefully watched, to gather them before they open and diſcharge the ſeeds; becauſe thoſe which are ſituated on the lower part of the ſtalk, will open long before thoſe on the upper part of the ſtalk are ripe; for which reaſon the pods ſhould from time to time be gathered as they ripen, and not ſuffered to ſtand till the ſtalks are pulled up, which is often practiſed. Thoſe pods which are ſituated on the lower part of the ſtalks, are much preferable to ſuch as grow near the top; for which reaſon thoſe who are very curious in the choice of their ſeeds, crop off the upper part of the ſpikes of flowers, and never ſuffer them to ſtand for ſeeds.

As theſe plants are very hardy, and require ſo little care in their culture, they are worthy of a place in every good garden; and during their continuance in flower, there are few plants which make a better appearance; for gathering to make flower-pots to adorn rooms, there is ſcarce any flower ſo proper; becauſe by their upright growth and long ſpikes, they riſe to a proper height above the pots; and when the ſeveral colours are ſkilfully intermixed they make a rich appearance, and continue long in beauty.

6—10. All the perennial Larkſpurs are propagated by ſeeds, which, if ſown in autumn, will more certainly ſucceed, than thoſe which are ſown in the ſpring; when the plants come up, they ſhould be kept clean from weeds, and where they are too cloſe together, part of them ſhould be drawn out, to allow room for the others to grow till the following autumn, when they muſt be planted where they are to remain; the following ſummer they will flower, and the roots continuing many years growing in magnitude, will produce a great number of flower-ſtalks.

11. The ſeeds ſhould be ſown where the plants are to remain.

["It is with great difficulty (ſays Gerarde) preſerved in our cold countries, albeit in ſome mild winters, I have kept it covered over with a little ferne to defend it from the injury of the march wind, which doth more harm unto plants, that come forth of hot countries, than doth the greateſt froſt."—This is a ſenſible obſervation; and although Mr. Miller affirms that the Staveſacre requires no other treatment than the common Larkſpur, yet we frequently find that the plants committed to the open air without protection in our climate are killed in ſevere ſeaſons.]

Leaves digitate.

DESCRIPTIONS, *&c.*

1. [*Root* perennial, white, toothed, long, of a pleaſant taſte. *Stem* a foot or a foot and a half in height, branched, round, and ſmooth. Leaves biternate; leaflets lanceolate, ſerrate, acuminate, ſmooth. *Flowers* from three peduncles forming a panicle or raceme, erect, faſciculed. Calyx pale green or yellowiſh.

lowiſh. Petals reddiſh yellow or yellowiſh red[a]. In the ſituation of the leaves it reſembles *Anemone*, in their form *Expatorium*. There is a gland on each ſide between the longer ſtamens and the calyx, and one ſurrounding the baſe of each ſhorter ſtamen. The ſtamens are all nearly of a length. In each cell are four ſeeds. Moſt of the upper flowers are abortive[b].

Native of Hungary, Auſtria, Idria in Friuli, Sileſia, &c. in woods. It flowers in april and may.—Called by Gerarde *Coral-toothed Violet*.

2. Bulbs produced from the axils of the leaves as in *Lilium bulbiferum*, and the fruit in like manner abortive[c].

Stem ſimple. Lower leaves have three pairs of leaflets and an odd one, which is confluent with the pair below it; they are bluntly lanceolate and ſerrate; the leaves above theſe have five leaflets, and the upper leaves are trifid or ſimple, acutely lanceolate, ſerrate. Corollas fleſh-coloured. The ſcaly bulbs in the axils of the upper leaves, falling off, take root, and propagate new plants; ſo that it rarely produces ſeed[d]. Root perennial: plant more tender than the others, petals purple, white or reddiſh. There is a gland between each ſhorter ſtamen and the calyx, and a ſmaller one cloven half way between the longer ſtamens and the calyx; ſometimes this gland is entire, and ſometimes it is trifid, with the middle tooth longeſt[e].—It flowers in april and may.

Native of Sweden, Denmark, Switzerland? Germany, Carniola, Piedmont, England, in moiſt woods and ſhady places. With us it is rare, having only been obſerved by Parkinſon in Highreed and Foxholes woods near Mayfield, Suſſex; by Blackſtone, in Old Park wood, near Harefield; and between Beaconsfield and Wycomb, Bucks, by Mr. Hudſon. Named by Gerarde *toothed*, or *dog-tooth Violet*. He cultivated it in his garden.

3. This may be fairly ſeparated from the next ſpecies, the difference in the leaves being permanent. They agree however in the flowers[f].

Native of Switzerland, the South of France and Sileſia. Mounts Jura and Saleva.—Cultivated in 1683, by Mr. James Sutherland[g].]

4. This riſes with a ſtrong ſtalk a foot and half high, with a leaf at each joint, compoſed of five lobes, four inches long, and near two broad in the wideſt part, ending in acute points, and deeply ſerrate; they are ſmooth and ſtand on long footſtalks. The flowers grow in looſe ſpikes at the top of the ſtalks; they are ſmall, of a bluiſh colour. Pods long and taper, filled with ſmall, roundiſh ſeeds.

[Calyx erect. An emarginate or ſlightly notched gland between the calyx and each ſhorter ſtamen. Leaves three or four, the two lower quinate, the two upper ternate[h]. Calyx purple; petals white, red or violet on the outſide[i].

Native of Switzerland, Savoy, the South of France, Carniola, Sileſia. Ray obſerved it abundantly on mount Jura.

Cultivated in 1656, by John Tradeſcant[k].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, or parting their roots; the ſeeds ſhould be ſown in autumn, ſoon after they are ripe, in a light ſandy ſoil and a ſhady ſituation: in the ſpring the plants may be taken up where they grow too cloſe, and tranſplanted out in the like ſoil and ſituation; where, after they have taken root, they will require no farther care, but to keep them clear from weeds: the ſecond year they will produce flowers, and ſometimes perfect their ſeeds.

The beſt time to tranſplant the roots is in october, when they ſhould be planted in a moiſt ſoil and a ſhady ſituation; for they will not live in a dry ſoil, or when they are expoſed to the ſun.

[The bulbs produced on the ſtalks of the ſecond ſort, if planted, will grow, and produce other plants.

Justicia malabarica. *Ait. hort. kew. 1. 27.*

Justicia figulata. *Lamarck encycl. n. 37.*

Flowers panicled bicalycled, panicles dichotomous.

DESCRIPTION, *&c.*

This genus differs somewhat from Justicia in habit, station, time, *&c.* but in the essential characters of the fructification agrees with it entirely: and as to the two anthers on each stamen, which gave occasion to the distinction and the name, some species of Justicia have them. Hence Swartz would dismiss the genus Dianthera entirely, and unite the species to Justicia. Since Schreber however retains the genus, I have left it as Linneus gave it.]

1. This is a low herbaceous plant with a perennial root, which sends out several weak stalks about four inches long. The leaves are roundish, hairy, sessile, of a dark green colour, and an aromatic odour. The flowers are produced from the side of the stalks in small spikes, and are in shape and colour very like those of Clinopodium. They come out at the end of july, but rarely produce seeds in England.

[Stem very simple. Leaves linear. Pedunculs alternate, the length of the leaves. Spikes ovate *.]

* Native of Virginia, and other parts of North America, whence the seeds have been sent to England.

[2. Stem herbaceous, a foot high, somewhat branched and erect, angular, jointed, smooth; the joints swelling. Leaves subsessile, decussated, oppolite, lanceolate, acute, attenuated at the base, smooth, nerved; on very short petioles. Peduncles axillary, filiform, terminated by filiform and umbelled spikes; flowers all directed one way, minute, pale blue. Bractes minute under the flowers. Segments of the calyx linear. Upper lip of the corolla half-vaulted; lower trifid spreading, with very minute bloody dots in two rows on the throat. Filaments under the vault of the throat: anthers two alternate, black. Germ ovate: style short: stigma simple bent in. Capsule ovate, attenuated at the base, containing four round, flatted seeds *.

According to Browne, it rises generally to the height of two or three feet, and is plentifully furnished with slender subdivided branches near the top; seeds two in each cell.

Native of Jamaica, in the low lands: and there called *Balsam-weed*.

3. *Root* annual. *Stem* herbaceous, erect, six-cornered, very finely villose, kneed, swelling above the

* Linn. spec. * Swartz.

knee, but little branched, a foot in height. Branches decuſſate. *Leaves* oppoſite, petioled, ovate-oblong, drawn to a point at the baſe, acuminate at the tip, entire, villoſe, ſpreading, unequal, from half an inch to two inches in length, the upper ones often larger. Petioles unguicular. *Peduncles* angular, villoſe, erect, half an inch in length: pedicels in whorls at the end of the peduncle, a line in length. *Bractes* of the pedicels two, oppoſite, ſubulate, ſpreading, villoſe on the outſide, the length of the pedicel: floral bractes approximating to the flower, two, oblong, drawn to a point at both ends, concave, convolute, ſimply acute at the tip, ciliate, villoſe, one larger than the other, unguicular: calycine bractes four, within the others, lanceolate, ſubulate, ciliate, unequal, only half the length of the others, incloſing one, two, or three ſeſſile flowers. *Calyx* divided almoſt to the baſe; the diviſions ſubulate, erect, ciliate, a line in length. *Corolla* purple, a little longer than the bractes, with a curved, cylindric tube. *Filaments* longer than the tube. Anthers alternate at the end of each filament, membranaceous, and of a pale colour. *Germ* ſuperior.—It differs from the Chineſe Dianthera, which it reſembles much, in having the flowers pedicelled, not ſubſeſſile; the peduncles longer and ſolitary in the axils, not aggregate; the bractes oblong and acute only, not ovate with a point almoſt like a ſpine; and the flowers from one axil only, not from both.—It differs from *Juſticia ſexangularis* in having oblong, not wedge-ſhaped bractes.

Native of Nagaſaki in Japan: flowering in auguſt [a].

4. Native of Botany iſland near New Caledonia.

5. Native of the Society iſlands [a].

6. This is a ſhrub, five feet in height, with an erect ſtalk, and brachiate branches. Leaves quite entire, oppoſite. Segments of the calyx filiform. Corolla white, with a long ſlender tube; the upper lip filiform and emarginate; the lower large and trifid. Anthers two on each filament, one over the other. Stigma acute.

Native of Cochinchina [a].

7. Stem erect, roundiſh, even, jointed: joints three inches long, narrowed at bottom: branchlets axillary, filiform, the length of the joints. Leaves oppoſite; thoſe on the ſtem petioled, lanceolate-ovate, acuminate, ſcarcely crenate, ſmooth, ſimply veined with the veins moſtly oppoſite, only half the length of the joints; thoſe on the branchlets ſeſſile. Spike at the top of the branchlets, peduncled, an inch long, ſmooth. Peduncle filiform. Flowers in whorls, two or three on each ſide, on very ſhort pedicels, and ſmall; the lower ones more remote. Bractes lanceolate, acuminate, a line in length. Calyx longer than the bracte, with awl-ſhaped ſegments. Corolla twice as long as the calyx, ſmooth on the outſide, the throat dotted with violet.—It differs from the two next ſpecies, in having all the bractes ſhorter than the calyx, the calyx ſimple, the corolla white dotted with violet, and awnleſs anthers.

8. Stem erect, angular, ſix-grooved, pubeſcent, jointed, the internodes two or three inches long, and the joints ſwelling. Leaves oppoſite, obtuſe, ſcarcely crenate, ſomewhat rugged along the nerves, a little villoſe, paler underneath, an inch and half long, with alternate veins: petioles the length of the leaves. Spike three inches long, ſubſeſſile. Flowers in whorls, ſeſſile, three on each ſide, the lower ones more remote, the upper ones crowded, ſmaller than in the preceding. Bractes two under each whorl, lanceolate, villoſe towards the edge, the length of the flower: under each flower two others, linear, villoſe, ſhorter. Calyx double: the outer almoſt the length of the bractes, three-parted with awl-ſhaped ſegments; the inner only half the length of the outer, five-cleft, with lanceolate, ciliate ſegments. Corolla villoſe on the outſide, white veined with purple; lower lip three-lobed, the lobes oblong, obtuſe, equal. Anthers purple, the lower ones with a white awn. It differs from the preceding in its ſix-grooved ſtalk, cordate-ovate obtuſe leaves, petiole the length of the leaf, flowers in whorls, and corolla ſtreaked with purple veins.

Native of Arabia Felix.

9. Stem ſhrubby, roundiſh, the thickneſs of a gooſe quill. Branches obſcurely quadrangular, ſubpubeſcent, ſcored with a line along the ſides; the internodes an inch long, the joints ſwelling. Leaves oppoſite, quite entire, thinly hairy, twice as long as the internodes, with alternate veins, on ſhort petioles. Spike peduncled, two inches long, ſomewhat hairy; flowers oppoſite, ſolitary, contiguous. Bractes three under each flower, linear-lanceolate, blunt, villoſe underneath, one larger, the length of the flower. Calyx double: the outer deeply three-parted; ſegments linear, obtuſe, villoſe, ſhorter by half than the bractes; the inner five-cleft, villoſe, a little ſhorter, with awl-ſhaped ſegments. Corolla villoſe on the outſide, the length of the bractes; lower lip trifid, the lateral ſegments lanceolate, the middle one oblong, obtuſe. Lower anther awned.

Forſkall regarded theſe three as varieties of D. americana; but they differ in the form of the leaves, the terminating ſpikes, and in having the lower flowers remote, not all crowded together in a ſort of head.

10. Stem ſhrubby. Branches obſcurely quadrangular, four-grooved, with hairs pointing backwards, and internodes half an inch in length. Leaves oppoſite, lanceolate, narrowed at the baſe into a very ſhort petiole, quite entire, bluntiſh, veinleſs, having four parallel villoſe nerves underneath, and being only half the length of the internodes. Spikes oblong, four-cornered, ſhorter than the leafs the axillary ones alternate and ſeſſile, the terminating one peduncled. Bractes in whorls, four together, ſhapiſh, imbricate, villoſe along the nerves, two larger. Calyx ſimple, five-parted; ſegments linear-lanceolate, ciliate, ſhorter than the bractes. Corolla pubeſcent on the outſide, a little longer than the bractes.

It differs from the next ſort in having grooved branches hairy backwards, ſeſſile leaves, four-cornered axillary ſpikes, ovate bractes in whorls, and a ſimple calyx.

11. Stem ſhrubby. Branches powdered and villoſe, obſcurely quadrangular, the angles ſcarcely ſcored with a line, the internodes an inch and half long. Leaves oppoſite, the lower oblong, the upper lanceolate, rounded at the baſe, quite entire, ſmooth, bright green, veinleſs, nearly the length of the internodes, on ſhort petioles. Spike cylindric, half an inch long, on a very ſhort peduncle. Bractes imbricate, ending in a ſomewhat prickly point: the loweſt nearly the length of the ſpike. Calyx double: the outer three-parted, with briſtle-ſhaped ſegments; the inner five-cleft, with linear-ſubulate, ſmooth ſegments, ſhorter than the bractes. Corolla pubeſcent on the outſide, longer than the bractes [a].

12. Stem herbaceous (according to the Supplement, ſhrubby, angular, rough with hairs.) Leaves oppoſite, ovate, acuminate, quite entire, petioled. Panicles axillary (terminating, *Suppl.*). Pedicels bifid, often trifid. Calyx double; outer deeply five-cleft, the dorſal ſegment lanceolate, almoſt the length of the corolla. Outmoſt bracte linear, double the length of the other. Corolla purple, bilabiate, divided. Anthers divaricated [a].

Native of the Eaſt Indies and Arabia Felix. It is annual, and flowers here in auguſt. Introduced in 1785, by Sir Joſeph Banks, Bart. [a]

The proper place of all theſe is between the ſecond and third ſpecies [a].

For other ſpecies reputed to be *Dianthera* by ſome authors, ſee *Juſticia*.]

[a] Thunberg. [a] Forſter. [a] Loureiro. [a] Vahl. [a] Linn. ſuppl. and Hort. kew. [a] Hort. kew. [a] Vahl.

PROPAGATION AND CULTURE.

1. This plant is very difficult to preserve in this country, for although it is hardy enough to live here in the open air, yet it is very subject to rot in winter; and if it is placed under shelter, it is apt to draw up weak, and soon after to decay.

[The others, being natives of the East or West Indies and other hot countries, must be preserved in the bark stove: but few of them have hitherto been introduced among us.]

DIANTHUS. (Διος ανθος, *Jove's-flower, or divine flower; from the fine colour and odour in some species.*) *Lin. gen. n.* 565. *Reich.* 614. *Schreb.* 770. *Juss.* 302. *Gærtn. t.* 129. Caryophyllus. *Tourn.* 174. Tunica. *Dill. elth.* 298.

Class. 10. 2. Decandria Digynia.

Nat. order of *Caryophylleï.*

GENERIC CHARACTER.

CAL. *Perianth* cylindric, tubular, striated, permanent, five-toothed at the mouth, furrounded at the base with four *scales*, of which the two oppofite are lower.

COR. *Petals* five; *claws* length of the calyx, narrow, inferted into the receptacle. *Border* flat: the plates outwardly wider, obtufe, crenate.

STAM. *Filaments* ten, fubulate, length of the calyx, with fpreading tips. *Anthers* oval-oblong, compreffed, incumbent.

PIST. *Germ* oval. *Styles* two, fubulate, longer than the ftamens. *Stigmas* bent back, acuminate.

PER. *Capfule* cylindric, covered, one-celled, gaping open at top four ways.

SEEDS a great many, compreffed, roundifh. *Receptacle* free, four-cornered, fhorter by half than the pericarp.

OBS. *In fome the ftyles fcarce exceed the length of the ftamens; in others they are very long, but rolled back in fuch a manner that the inflexion of the flower is not neceffary.*

ESSENTIAL CHARACTER.

Cal. cylindric, one-leafed; with four fcales at the base. *Petals* five, with claws. *Capf.* cylindric, one-celled.

SPECIES.

* *Flowers aggregate.*

Betonica coronaria arborea cretica. *Baub. hiſt.* 3. 328.
Stem ſhrubby, leaves oblong ſomewhat fleſhy, calycine ſcales numerous blunt cloſely imbricate very ſhort.

25. Dianthus fruticoſus.
Lin. ſpec. 591. *Reich.* 2. 339.
D. arboreus β. *Smith in Linn. tranſ.* 2. 303.
Caryophyllus græcus arborcus, leucoii fol. peramaro. *Tournef. cor.* 23. *inſt.* 1. 183. *t.* 9.—1. 219. *edit. oct.*
Stem ſhrubby, leaves lanceolate.

26. Dianthus juniperinus.
Smith in Linn. tranſ. 2. 303.
Caryophyllus creticus arborcus, juniperi folio. *Tournef. cor.* 23.
C. ſylveſtris arborcus. *Alpin. exot.* 39. *t.* 38.
Stem ſhrubby, leaves awl-ſhaped, calycine ſcales about four, obovate, mucronate and pungent, patulous, only half the length of the tube.

27. Dianthus pungens. *Prickly-leaved Pink.*
Lin. ſyſt. 419. *Reich.* 2. 339. *mant.* 240.
Flowers ſolitary, ſtems few-flowered, calycine ſcales very ſhort mucronate ſpreading, tube gibbous, petals entire.

28. Dianthus hiſpanicus.
D'Aſſo aragon. n. 371. *t.* 3.
Stem uſually one-flowered, calycine ſcales ovate, petals linear quite entire.

29. Dianthus Libanotis.
Billard. ic. ſyr. 1. 14. *t.* 5.
Flowers ſubaggregate, calycine ſcales ſix acuminate recurved, corollas multifid-capillary bearded at the throat, ſtem erect.

30. Dianthus pumilus.
Vahl ſymb. 1. 32. *Forſk. arab.* 111. *n.* 284.
Stemleſs; leaves linear.

DESCRIPTIONS, &c.

Theſe beautiful plants are chiefly herbaceous; ſome few however are ſuffruticoſe. Moſt of them are hardy, and perennial or biennial; ſome of the ſmaller wild ſorts only are annual. Stalks annual, from one to three feet in height. Leaves oppoſite, narrow, entire. Flowers terminating, many

many aggregate, ſome ſolitary or ſeveral together but diſtinct.

There is much confuſion in this genus from the incorrectneſs of authors. Dr. Smith obſerves, in his excellent paper on this genus, in the ſecond volume of the Linnean Tranſactions, that the ſynonyms form the moſt inextricable botanical labyrinth he ever entered. I wiſh he may not find many other labyrinths yet more inextricable than this.

1. The Sweet-William has a perennial fuſiform root. Stem upright, jointed, ſmooth, a foot and half high, branched. Leaves ſoft, veined, connate, from half an inch to almoſt an inch broad in the wideſt part, bright green. Bundles of flowers compact, umbelled, ſeſſile. Petals ſerrate, when wild red either plain or ſpotted with white, ſmaller than in many of the genus[a]; the border the length of the calyx. Calycine ſcales, four, five, or ſix, ovate at the baſe, but putting out narrow ſtiff points, reaching almoſt as high as the calyx[b]; hence this ſpecies is named *barbatus* or bearded.

The native country of this plant, ſo common in our gardens, was not known to Linneus; Dodonæus however, in 1552, mentions its being found wild in Germany, and Profeſſor Hoffman confirms this in his Germanys Flora, 1791[c].

Scopoli, Allioni, and Krocker inſert it in their floras; and Dr. Stokes ſets it down as growing at King's-Weſton near Briſtol: but it is probably not originally wild.

This flower appears in the catalogue of Gerarde's garden, in 1596, and was probably cultivated much earlier, being eſteemed (as Gerarde expreſſes it "for "its beauty to deck up gardens, the boſoms of the "beautiful, garlands and crowns for pleaſure."—Parkinſon ſays that the narrow-leaved kinds are called Sweet-Johns, and the reſt Sweet-Williams: that the broad-leaved unſpotted kinds are named in ſome places Tolmeiners and London Tufts, and that the ſpeckled kind is termed London Pride.

The variations of colour are numerous, and might have been more ſo if this ſpecies had attracted the ſame minute attention as the floriſts have given to the Pink and Carnation. The principal varieties are the following:

1. Broad-leaved, or Sweet-Williams.
2. Narrow-leaved, or Sweet-Johns.

Each of theſe have the flowers

1. Single, and
2. Double.

The principal variations of colour are

1. Deep red.
2. Pale red. Roſe-coloured. Fleſh-coloured.
3. Purple, inclining to blue.
4. Purple and white.
5. White ſpotted.
6. Red, with white borders: figured by Miller. And, Purple with white borders: figured by Curtis, as the Painted Lady.
7. Pure White.

With all the intermediate ſhades of the above colours, both ſingle and double.]

The broad-leaved, with very double flowers of a deep purple, inclining to blue, burſting the calyx, is not ſo much eſteemed. The double Roſe Sweet-William, with flowers of a fine deep roſe-colour, and ſmelling ſweet, is much valued; for it does not burſt. The Mule, or Fairchild's Sweet-William, is one of the narrow-leaved ſorts. It is ſuppoſed to have been produced from ſeeds of a Carnation impregnated by a Sweet-William. The flowers are of a brighter red than either of the former; their bunches are not quite ſo large, but the flowers have an agreeable odour.

[2. This differs from the foregoing ſort, in having the leaves narrower by half, ſtiffer, and marked with three principal nerves, not one only, as in that. The ſtem is a little ſcabrous, not perfectly ſmooth, as in the former. The petals are diſtant, and villoſe, not ſmooth, on their upper ſurface. The piſtils are longer than the tube[a].

Krocker adds other differences: that the leaves are glaucous and connate; the ſtem higher; the bundles of flowers ſmaller and leſs cloſe, eſpecially in the wild plants; the calycine ſcales broader; petals ſerrate, purple, with ſharp auricles; calyx ample, viſcid, pale brown or dark purple, with a green baſe; anthers violet-coloured; ſeeds compreſſed, roundiſh, with a black membranaceous edge.

In a fertile ſoil there will be fifteen flowers on a ſtem, in a barren ſoil fewer, and ſometimes only one; this therefore is an intermediate ſpecies between the aggregate and one-flowered *Dianthi*.—There are ſometimes ſeven calycine ſcales. The petals are of a deep red colour, ovate, and five-toothed[b].

Pollich could not obſerve any toothlets at the throat, which Krocker (from Haller) calls the auricles.

There are two pairs of ſcales to the calyx (according to Allioni); a crown of black dots is at the origin of the claws in the petals, and at the ſame place are a few white hairs. Flowers terminating, on two branches, from four to ſix. Perennial.

Native of Germany, Switzerland, Carniola, Italy, Sicily, Spain. Haller ſays it is very common about Aigle; and I gathered it in flower on the 28th of april 1779, at Chatelaine near Geneva. With us it does not flower till july.

According to the Kew catalogue, it was introduced in 1771, by Monſ. Richard.

3. Height from two to three feet. Leaves ſmooth, flat, connate at the baſe, an inch from the joint, ſtriated underneath, lanceolate, erect. The head of flowers at the end of the ſtem is formed in this manner: a pair of elliptic leaves emitting a long awn has two ſhort peduncles riſing from it on each ſide; hence the ſtem riſing a little higher, has three other very ſhort peduncles, each bearing three flowers. Similar bractes contain the calycine ſcales, which are four in number, tranſparent, reddiſh white, ending in a ſhort brown awn. Calyx brown, very cloſely ſtriated. Petals ſcarlet, rhomb-ſhaped, with few unequal teeth; there are uſually two on each ſide, and at the end two or three ſhort ones; on the upper ſurface are a few erect black hairs. The flower has hardly any ſmell. The plant is perennial.—Native of Piedmont, in dry hilly places, by the ſides of woods[c].

This, which is given as a variety of the foregoing ſpecies by Linneus, is certainly diſtinct, in Allioni's opinion.

4. This ſort reſembles the foregoing very much, but the ſtem is narrower, and the leaves are more graſſy and more keeled; the flowers are bundled in like manner as that is with the common calyx ſcariſe: it differs, however, in having the calycine ſcales with the awns the length of the corolla, which in the laſt ſpecies are ſhorter; alſo in having the petals biſid, with three teeth on each ſide, rufous underneath, and yelloviſh within; the border ſhorter than the calyx: whereas the petals of the Carthuſian Pink are not emarginate or biſid, but rounded, toothed, and bright purple on both ſides[d].

It has the entire habit of Sweet-William; the flower-ſtems are upright, and about a foot and half high; the leaves are ſomewhat like thoſe of Carnation, but of a darker green; the bundles of flowers are cloſe; ſome of the corollas are yellow, and others of a ruſty iron colour in different bundles, and ſometimes even in the ſame bundle. The ſeaſon of flowering is in july, but when the weather proves cool and moiſt, there will be a ſucceſſion of flowers till the end of ſeptember. The roots will abide two or three years, but the young plants of

[a] Krocker. [b] Scopoli. [c] Curtis.

[a] Linn. ſpec. [b] Scopoli. [c] Allioni. [d] Linn. mant.

the ſecond year produce the greateſt quantity of flowers. This ſpecies was diſcovered by Barrelier in the mountains of Abruzzo in Italy; and it has been ſince diſcovered in Spain, whence Mr. Miller received the ſeeds, which have ſucceeded in the Chelſea garden[h]. (1756).

5. Root annual. (biennial. *Ray hiſt.*) Stems erect, a foot or a foot and half in height, round, pubeſcent, roughiſh, ſwelling at the joints, towards the upper part a branch comes forth at each joint, terminated with a ſmall bundle of from two to four flowers. Leaves linear-lanceolate, connate, bright green, erect, entire, pubeſcent on both ſides and roughiſh, three-nerved, three inches long, and two lines broad. Each flower has two or four bractes, or calycine ſcales, which are ſubulate, ſtriated, and hirſute. Calyxes longer and narrower than in the Carthuſian Pink, ſtriated and villoſe. Claws of the petals long; border purple, dotted with red and white, ſmooth, except that they are ſlightly hairy towards the throat, obtuſe, and finely notched at the end, (acuminate, with one or two teeth. *Lin. ſpec.*) a line and half in breadth, and nine lines or more in length, including the claws. Anthers violet-coloured. Stigmas red-purple, flexuoſe, pubeſcent[i].—It flowers in july and auguſt.—Native of Gothland, Denmark, Upper and Lower Sileſia, the Palatinate, and other parts of Germany, France, Switzerland, Italy, Spain, and England. From having been found in a meadow near Deptford by Johnſon, it obtained the name of *Deptford Pink*; it occurs in Charlton wood, and other places in Kent; near Croydon, between Dorking and Mickleham, Dulwich, Oak of Honourhill, Streatham, &c. in Surrey; in Norfolk; about Perſhore and Eckington in Worceſterſhire; near Ketley in Shropſhire; and at Clarkton Leap, near Worceſter. Near Reading in Berkſhire. Near Caverſham. By the road from Hareſield to Chalfont, St. Peter's. In a little wood near Highgate, and in Tuddington field.

6. Stem decumbent at the baſe, then erect, round, even, ſmooth, ſimple, or very rarely divided at top, a foot in height. Leaves oppoſite, petioled, ovate, acute, entire, ſmooth, nerveleſs, erect, an inch in length, the upper ones ſmaller. Petioles broad, ſtem-claſping. Flowers terminating, faſtigiate. Calyx the length of the tube of the corolla, ſtriated, ſmooth; calycle ovate at the baſe, then lanceolate, acuminate, keeled, half the length of the calyx. Corolla crenate.—Native of Japan[k].

7. Root annual. Stem uſually ſingle, erect, decumbent only at bottom, very ſmooth, ſwelling at the joints, a ſpan or a foot high, ſometimes more. A pair of awl-ſhaped leaves at each joint, connate, quite entire, bright green, ſmooth. Flowers in a crowded head on the ſummit of the ſtalks, three or four together, ſurrounded by large ſcaly bractes nearly hiding them; they open one at a time, the uppermoſt firſt, riſing up from the bractes; when they fade, drying up and withdrawing again, ſo that they are a conſiderable time in flowering. Corollas ſmall, ſlightly bifid, not crenate, red or roſe-coloured, ſometimes varying to white; they expand about eight in the morning, and cloſe about one in the afternoon[l].

Native of Denmark, Germany, France, Switzerland, Carniola, Italy, Sicily, Spain, England. With us it is rare, in ſandy paſtures, and has been obſerved only at Selſey Iſland in Suſſex, near Norwich, on Landridge hill, and at Hanley caſtle, in Worceſterſhire.—Between Hampton Court and Tuddington. *Merret.*—It flowers in july and auguſt; and is known by the name of Childing Sweet Williams, or Childing Pink.—Gerarde calls it Catchfly or Littlewort; but he has confounded it with the true Catchfly.

8. It is doubtful whether this be a diſtinct ſpecies. Haller thinks it is not; Leers ſays it is hardly different; and Linnæus affirms it to be the daughter of the Childing Pink, and of courſe very nearly allied to it. All the ſpecimens that Dr. Smith has ever ſeen were evidently D. prolifer: there is little doubt, therefore, but that it is no more than a variety of that ſpecies.—The leaves are narrower; the ſtem is branched; the flowers ſolitary, not aggregate. The calyx has four pairs of ſcales, the inner ones gradually larger, and more obtuſe. The corolla very ſhort, ſcarcely prominent beyond the tube[m]. Annual.]

It is a very diminutive plant, ſeldom riſing ſix inches high, terminated by a ſingle flower, of a pale red colour; the leaves are ſhort and narrow, and grow in cloſe heads. [Native of Germany and Switzerland.

9. This ſpecies, ſo well known in its improved ſtate, in gardens, is thus deſcribed in its natural ſtate, by Haller.—Root large, woody, branched. Stem a foot or eighteen inches high, decumbent at bottom, jointed, branched. Leaves glaucous, ſmooth, linear, a line in breadth. Every branch is terminated by one, two, or three flowers. The calycine ſcales are ſhort, broad and awned; but ſometimes they are wholly wanting. The petals have long claws, the lamina or border repreſents the ſector of a circle, and is finely ſerrated about the edge; it is not lanuginous at the baſe: the claw is green, the border is roſe-coloured. This flower has a pleaſant ſmell, but not the ſpicy odour of the garden plant. Seguier ſays that it is without ſmell. Scopoli adds that the ſtem is angular, and that the leaves, when viewed through a magnifying glaſs, appears finely toothed.

It grows on rocks and walls, and in dry ſoils.

This fine flower, which has long been deſervedly eſteemed, both for its ſuperior beauty, and rich ſpicy odour, muſt have been unknown to the ancients, in its cultivated improvement; otherwiſe it muſt have been deſcribed by the naturaliſts, and ſung by the poets, as well as its rival the roſe. Carnations and Pinks have, however, been cultivated time immemorial in Europe, and were among the few favourite flowers of our remote anceſtors.

CARNATIONS.

Parkinſon, in his Paradiſus, publiſhed in 1629, has given a very full account, with figures, of the Carnations then in cultivation. He divides them into Carnations, or the greateſt ſorts in leaf and flower, and Gilloflowers, or ſuch as are ſmaller in both reſpects. The orange-tawney or yellow Gilloflower, now little eſteemed, had then been lately introduced. Gerarde (1597) informs us, "that a worſhipful merchant "of London, Maſter Nicholas Lete, procured it "from Poland, and gave him thereof for his garden, "which before that time was never ſeen nor heard "of in theſe countries."

Of Carnations, the diligent Parkinſon recites nineteen, and of Gilloflowers thirty varieties. Though theſe have been ſupplanted by modern flowers, and the florifts are daily producing new ones, yet it may not be unacceptable to the curious, to recite the names of thoſe which were in favour almoſt two centuries ago.

CARNATIONS. *Gray*, red and *blue Hulo*. *Grimelo* or *Prince*. *White* or *delicate*. *French*. *Grand*, or *great Harwich*, or *old Engliſh*. *Chryſtall* or *Chryſtalline*. *Red Chryſtall*. *Fragrant*. *Striped Savadge*; *bluſh*, and *red Savadge*. *Oxford*. *King's* or *ordinary Briſtow*. *Greateſt Granado*. *Gran Pere*. *Camberſine*. *Great Lumbard Red*.

GILLOFLOWERS. *Luſty Gallant* or *Weſtminſter*. *Briſtol blue*. *Briſtol bluſh*. *Red Dover*. *Light* or *White Dover*. *Fair maid of Kent*, or *ruffling Robin*. *Queen's*. *Dainty*. *Braſil*. *Granado*. *Turky*. *Poole*. *Light* or *pale Pageant*. *Sad Pageant*. *Braddhaw's dainty Lady*. *Beſt White*. *London White*. *Stamell*. *Purple*. *Gradeline*. *Blue*. *Bluſh*. *John Wittie his great tawny*. Divers other Tawnies. Many ſorts of Bluſhes. Some varieties of reds. *Striped Tawny*.

[h] Mill. ſig. [i] Haller, Pollich, Krocker. [k] Thunberg. [l] Woodw. Mſs. Withering, Haller, Pollich. [m] Linn. ſpec.

Marbled Tawny. Maſter Tuggie's Princeſs. Flaked, feathered, and *ſpeckled Tawny. Maſter Tuggie his Roſe Gilloflower.*

This Maſter Tuggie was the moſt famous man of his time for the cultivation of theſe fine flowers: and accordingly Johnſon (Ger. herb. edit. 1636. p. 589) after referring to the work of his friend Mr. John Parkinſon, adds, "if they require further ſatisfac-"tion, let them at the time of the year repair to "the garden of Miſtreſs Tuggy, the wife of my late "deceaſed friend Mr. Ralph Tuggy, in Weſtmin-"ſter, which in the excellency and variety of theſe "delights exceedeth all that I have ſeen."

Gerarde has ſeveral names beſides Clove-Gilloflowers and Carnations:—as Sops in wine, Pagiants or Pagion colour, Horſe-fleſh, Blunket, &c. expreſſive of the different colours.—The old name *Gilloflower*, was ſuppoſed by Parkinſon to be corrupted from July-flower, and Ray has adopted the notion; but it is erroneous: for it is evidently derived from the French *Giroflée* or *Geroflier*, and accordingly Chaucer writes it *Giroffer*.

Many of the fine varieties of Carnation eſteemed in former times are figured in Parkinſon's Paradiſus, Hortus Eyſtettenſis, De Bry's Florilegium, Paſſæi Hortus Floridus, Swertii Florilegium, &c. And ſome of the modern ones, by Mr. Sowerby, in his Flora Luxurians. Rea (in his Flora, 1702.) has a liſt of 360 good ſorts of Carnation.]

Modern Floriſts diſtinguiſh the Carnation into four claſſes.

Firſt *Flakes*, of two colours only, and their ſtripes large, going quite through the leaves. One of theſe, the Roſe-leaved Flake, is figured by Miller, t. 121.

Second *Bizarres*; with flowers ſtriped or variegated with three or four different colours, in irregular ſpots and ſtripes. See Curtis's magazine, t. 39.

Third *Piquettes* or *Piquettées*; having a white ground, and ſpotted or pounced with ſcarlet, red, purple, or other colours.

Fourth *Painted Ladies*; theſe have the petals of a red or purple colour on the upper ſide, and are white underneath.

Of each claſs there are numerous varieties, but chiefly of the third, which ſome years ago was in moſt eſteem with floriſts; but of late years the Flakes have been in greater requeſt. To enumerate the varieties would be needleſs, ſince they are not permanent, and every country produces new flowers almoſt every year, which though at firſt raiſing they may be greatly valued, in two or three years become ſo common as to be of little worth, eſpecially if they are defective in any one property; and are turned out to make room for new comers. For the variety of pompous names we refer therefore to the liſts publiſhed yearly by floriſts and nurſery-men, who either raiſe theſe flowers from ſeed, or import them from abroad.

The following are what the floriſts call the good properties of a Carnation.

1. The ſtem of the flower ſhould be ſtrong, and able to ſupport the weight of the flower without hanging down.

2. The petals ſhould be long, broad and ſtiff, and pretty eaſy to expand; or, as the floriſts term it, ſhould make free flowers.

3. The middle of the flower ſhould not advance too high above the other parts.

4. The colours ſhould be bright, and equally marked all over the flower.

5. The flower ſhould be very full of petals, ſo as to render it, when blown, very thick in the middle, and the outſide perfectly round.

[To this we may add, that the ſtem ſhould not only be ſtrong, but ſtraight, and not leſs than thirty, or more than forty-five inches high. The flower ſhould be at leaſt three inches in diameter, and the petals well formed, neither ſo many as to appear crowded, nor ſo few as to appear thin. The lower or outer circle of petals, commonly called the guard leaves, ſhould be particularly ſubſtantial; they ſhould riſe perpendicularly about half an inch above the calyx, and then turn off gracefully in a horizontal direction, ſupporting the interior petals; which ſhould decreaſe gradually in ſize, as they approach the centre, which ſhould be well filled with them. All the petals ſhould be regularly diſpoſed, and lie over each other in ſuch a manner as that their reſpective and united beauties may meet the eye all together; they ſhould be nearly flat, or at moſt have a ſmall degree of inflection at the broad end: their edges ſhould be perfectly entire, without notch, fringe, or indenture. The calyx ſhould be at leaſt an inch in length, ſufficiently ſtrong at top to keep the baſes of the petals in a cloſe and circular body. The colours ſhould be diſtinct, and the ſtripes regular, narrowing gradually to the claw of the petal, and there ending in a fine point. Almoſt one half of each petal ſhould be of a clear white, free from ſpots.

PINKS.

Pinks do not ſeem to have attracted any great notice among our anceſtors. Parkinſon has given very few varieties: as white, red, purple, Granado, matted and bluſh, both ſingle and double. Rea ſays, that there are many ſorts, but of little eſteem, ſerving only for the ſides of borders in ſpacious gardens, and ſome of them for Poſies, mixed with the buds of the Damaſk Roſe; and that the beſt are the feathered Pinks. It is only within the preſent century, and particularly of late years, that Pinks have been much improved and varied, ſo as to be greatly valued among floriſts.]

The principal varieties are, the Damaſk, white Shock, Pheaſant Eye, common Red, Cob's, Dobſon's, white Cob, and Bat's. The old man's Head, and Painted Lady Pinks rather belong to the Carnation.

The Damaſk Pink is the firſt of the double ſorts in flower. This has but a ſhort ſtalk; the flower is not very large, and not ſo double as many others; the colour is of a pale purple, inclining to red, but it is very ſweet.

The next which flowers is the white Shock, which was called from the whiteneſs of its flowers, and the borders of the petals being much jagged and fringed, the ſcent of this is not ſo agreeable as of ſome others.

Then come all the different varieties of Pheaſants Eye, of which there are frequently new varieties raiſed, which are either titled from the perſons who raiſed them, or the place where they were raiſed; ſome of theſe have very large double flowers, but thoſe which burſt their pods are not ſo generally eſteemed.

The Cob Pink comes after theſe to flower; the ſtalks of this are much taller than thoſe of any of the former; the flowers are very double, and of a bright red colour; this having the moſt agreeable odour of all the ſorts, merits a place in every good garden. The time of the Pinks flowering is from the latter end of may to the middle of july, and frequently that ſort of Pheaſant Eye which is called Bat's Pink, will flower again in autumn.

The old Man's Head Pink, and the painted Lady, do not flower till july, coming at the ſame ſeaſon with the Carnation, to which they are more nearly allied than to the Pink. The firſt, when it is in its proper colours, is purple and white ſtriped and ſpotted, but this frequently is of one plain colour, which is purple; this ſort will continue flowering till the froſt in autumn puts a ſtop to it, and the flower having an agreeable ſcent, renders it valuable. The painted Lady is chiefly admired for the livelineſs of its colour; for it is not ſo ſweet, or of ſo long continuance as the other.

[Pinks are here kept along with Carnations, but they do not ſeem to be all varieties of the ſame ſpecies: probably the Red Pinks take their riſe from this, whilſt the Pheaſant Eye Pinks ſeem to derive their origin from *D. plumarius*. Some give them all as variations of *D. deltoides*, which is not likely.

10. The

10. The herb of this ſort is very like that of D. Caryophyllus. But it ſcarcely multiplies itſelf by the root. The ſtem has only three or four ſimple, long, one-flowered branches. The calyx has only two, ſhort, acute, not acuminate ſcales. The corolla is yellow, and underneath pale green: the petals are revolute on the ſides, hence they are convex, not ſpread out flat, but diſtant, ſhorter than the tube of the calyx, very obtuſe, ſlightly emarginate, ſcored with a line. Stamens white, the length of the calyx. Piſtils finally becoming of the length of the corolla. The flower opens at half after twelve at noon, and cloſes at ten o'clock at night.—Obſerved near Conſtantinople by Forſkaehl, and in Paleſtine by Haſſelquiſt [a]. Dr. Smith remarks, that this is the only ſort he has ſeen, which has the calyx ſmooth in the lower part, while the upper half is ſtriated, and that very ſtrongly and accurately.

11. Barren ſtems numerous, reclining, putting forth roots, flowering ſtems ſix to eight inches high, columnar below, ſquare at top, ſlender, weak, but uſually erect, ſometimes ſimple, ſometimes branched or dichotomous, ſwollen at the joints, ſlightly pubeſcent. Leaves in pairs at each joint, linear or ſubulate, nearly the length of the internode, converging to the ſtalk, and embracing it at the baſe, ſlightly pubeſcent; thoſe of the barren branches narrower. Peduncles round, downy, from the ends of the ſtem and branches, ſingle, or two from the ſame joint, each bearing one flower. Petals toothed at the edge, bright red above, pale beneath. According to Ray reddiſh, with a ring of deeper-coloured dots ſurrounding the eye—with dark purpliſh teeth near the throat, and beſet with white ſilvery points, with hairs proceeding from them, as Pollich liss it [a]. The petals vary much in colour, being ſometimes of a very pale fleſh colour, ſometimes deep red, but they are always marked with a ring of deeper red dots near the centre of the flower [b].

Dillenius diſtinguiſhes this by the ſcales of the calyx being much more pointed; the corolla of a deeper colour, with numerous ſilvery dots, and its flowering later, namely in june and july. It continues flowering till late in autumn.

Paſtures and heaths, on a light ſoil, in Sweden, Denmark, Germany, Spain; in England not uncommon, as on Hampſtead heath, Dupper's-hill near Croydon, about Hampton Court Park, Beacon-hill near Feverſham in Kent, not far from Slough near Windſor. In Bedfordſhire near Sandy; Cambridgeſhire, Suffolk, Norfolk, at Cley, near Hillborough in the way from Brandon, &c. Nottinghamſhire, Derbyſhire, Weſtmoreland, Shropſhire, Somerſetſhire; and King's Park, Edinburgh.

There is a variety common in gardens; which has white flowers, with a beautiful purple ring, and leaves rather more glaucous than in the common ſort. This is the true D. glaucus of Linneus, and perhaps of Lightfoot. It has, indeed, generally four ſcales to the calyx, but ſo has D. deltoides frequently [c].

12. Leaves linear, very narrow, three-ſided, channelled, ſtiffiſh, connate, in tufts, ſcabrous on the edge and keel. Stem filiform, proſtrate, bearing one or two flowers, which are remote and ſweet-ſcented. Calycine ſcales orbiculate, preſſed cloſe. Petals blood-red, crenate, not feathered or villoſe. Styles ſtanding out, recurved. Perennial.—Native of mountains in the South of Europe [d]. This is the ſame with D. virgineus. n. 21 [e].

13. The circle is purple, and there is a purple tinge on the upper ſurface from a number of very fine lines. Stem rather angular; that and the leaves covered with a microſcopical woollyneſs. Peduncles ſolitary, or in pairs. Calycine ſcales in two oppoſite pairs, ſkinny at the edges, the two inner ones largeſt. Teeth of the calyx ſkinny at the edges, and pointed. Petals ſtained with pink at the baſe of the lamina. According to Dillenius, there is a purple circle on the corolla, and the petals have a purple tinge from a number of very fine lines on the upper ſurface. Willich ſays, that the circle or ring is double, the inner pale, the outer broader and ſcarlet, both toothed. Anthers gray. Stigmas white, woolly. Receptacle nearly as long as the ſeed-veſſel [f]. The flowers have no ſcent.

Dr. Smith, to whom we are much obliged for elucidating this genus, deſcribes it thus. Root woody. Stalks ſeveral, a ſpan high, erect, ſimple, ſmooth, quadrangular, having two or three pairs of leaves on them, one-flowered, ſcarcely ever two-flowered. Leaves linear-lanceolate, bluntiſh, glaucous. Scales of the calyx only one third of the length of the tube, ovate-roundiſh, bluntly mucronate, ſtriated. Petals fleſh-coloured, with a double row of blunt notches, marked with lines, and bearded at the baſe [g].

Native of Switzerland and England. On Chedder rocks in Somerſetſhire.

14. Petals white above, greeniſh white underneath, with the tip violet-coloured on both ſides. This differs from the foregoing, in having the petals ſcarcely crenate, and in not having the purple circle on them.—It is a native of the Cape of Good Hope, where it was obſerved by Mr. Francis Maſſon; introduced 1787. It is perennial, and flowers in auguſt [h].

15. The flower ſtems of the *China Pink* are from ſix to eight or nine inches high, branching out on every ſide; the branches grow erect, and are terminated each by one flower. The flowers have no ſcent, but having a great variety of colours, they are a conſiderable ornament to the flower-garden from july until autumn froſts put a ſtop to them. They have been greatly improved by culture; ſome flowers being as full of petals as the beſt double Pinks, and diſplaying the moſt glowing and vivid red colours.

This ſpecies is a native of China, whence the ſeeds were ſent by the French miſſionaries to Paris, about the year 1705. The flowers which were for many years produced in the European gardens were ſingle, till about the year 1719, when many double flowers were produced in ſome of the gardens at Paris; but whether theſe aroſe from ſeeds of the ſingle ſort, or from new ſeeds obtained from China, is difficult to determine; the firſt time I ſaw plants with double flowers in any of the Engliſh gardens was in the year 1722. The roots will often laſt two years in a dry ſoil; but they are generally raiſed from ſeeds every year [i].

[In the nurſery-grounds, it is generally known by the name of *Indian Pink*. Dr. Smith mentions his having a plant from Mr. Sikes's garden at Hackney, which ſeems to be a mule between this ſpecies and D. barbatus or Sweet William.

16. Wild about Montpellier and Verona, and in Piedmont. Perennial.

17. Stems aſcending, a foot or eighteen inches in height, branched. Leaves of a grayiſh or glaucous hue, a line and half wide, very ſharp at the end. Flowers one, two, ſeldom three, at the ends of the branches; ſweet-ſcented. Calyx glaucous-green, longer than in the other ſpecies. Petals large, light red or bright purple, ſometimes white, with a circle of red; deeply jagged, having a red down at the baſe of the lamina or border: anthers red. Capſule ſhorter in proportion than in the other ſpecies [k].

It flowers from june to auguſt, and is perennial.

Native of Europe and North America, on rocks, mountain paſtures, and dry woody places. Cultivated in 1629 [l].

18. Stalks a ſpan high, ſmooth and even. Leaves linear, very narrow and ſhort, bluntiſh, ſmooth and

[a] Linn. ſpec. [b] Ray, Pollich, Withering, Woodw. Mſs. [c] Engl. bot. [d] Dalib. [e] Linn. ſuppl. [f] Smith in Linn. tranſ. 2. p. 295. [g] Withering and Stoker. [h] Linn. tranſ. 2. 300. [i] Hort. kew. [k] Mill. fig. [l] Krock. Scop. Haller. [m] Park. parad.

even. Flowers two or four on a ſtalk, erect. Tube of the calyx ſlender, ſtriated, with lanceolate, ſtraight, very ſharp teeth, with four ſcales at the baſe, exactly oval, ſtriated on the back, with a ſhort ſpreading dagger-point. Petals narrow, irregularly cut to the very baſe into very fine ſegments. It varies with a white flower. Found in Armenia by Tournefort [a].

19. The ſtem is a foot or eighteen inches in height, procumbent at the baſe, and then erect, round, ſomewhat two-edged on the upper part, ſmooth, branching only at top. Leaves like thoſe of narrow-leaved Sweet-William, connate, lanceolate-linear or linear-ſubulate, acute, quite entire, bright green, ſmooth, marked with lines and a riſing nerve, rough on the edge, green not glaucous. Flowers erect, uſually two terminating each branch, on ſhort peduncles; ſometimes there are more, and ſometimes there is only one. Calyx ſlender, ſtriated, with erect lanceolate ſharp teeth. Calycine ſcales four, ſometimes more, obovate, pointed, ſtriated, one third the length of the calyx. Petals pale red, ſometimes white, hairy at the baſe of the border, ſprinkled with bloody ſpots. The flowers ſmell very ſweet, eſpecially in the evening. Capſule cylindrical, a little longer than the calyx, glittering like gold duſt, ſmooth, four-parted [b]. According to ſome it is perennial, according to others biennial, and even annual. Mr. Miller ſays that the roots will live three or four years, but that the flowers are in their greateſt beauty the ſecond year from ſeeds. It is probably therefore biennial naturally.

Native of Denmark, Lapland, Germany, Switzerland, France, Italy, Spain: flowering from july to ſeptember. I gathered it in flower in auguſt 1779, on mount Scheidegg, in going from the vale of Haſli to that of Grind-lwald, in Switzerland. Dr. Smith obſerved it near Geneva.

20. Stalks diffuſed, woody at bottom, twiſted, branching very much; flowering branches aſcending, a foot long, leafy, round, ſmooth, divided at top into two or three branches, which are one-flowered. Leaves awl-ſhaped, mucronate and pungent, glaucous, rugged on the edge; ſtem-leaves ſhorter than the internodes. Flowers fleſh-coloured, void of ſcent. Calycine ſcales fix, the inner ones often membranaceous about the edge. Tube of the calyx ſtriated, gradually narrowing towards the top; teeth erect, membranaceous about the edge. Corolla ſmall, crenate, beardleſs.

Native of the South of France, near the coaſt. Obſerved by Brouſſonet [c].

21. That this bears a great affinity to *D. plumarius*, is clear from the throat of the petals; which are more oblong, divided, and cut beyond the middle of the diſk, (whereas in that they are only multifid) at the baſe is a ſharp, livid ſpot, with purpliſh hairs ſcattered over it [d].

Stem a finger or ſpan in length, erect, round, almoſt naked, having only one pair of leaves on it, and ſuſtaining one flower. Root-leaves abundant, in bundles, ſmooth, narrow, obtuſe, ſtiffiſh. Petals white, not crenate, reſembling thoſe of *D. plumarius*, and ſmelling very ſweet, eſpecially in the evening [e].

According to Scopoli, the leaves are tooth-letted; and the four calycine ſcales lanceolate, two of them longer than the lamina of the petal.

Mr. Miller ſays that the flower is ſweet, but pale-coloured and ſmall.

Native of Scania, in drifting ſand. Sileſia, on the borders of Saxony [f]. In Carniola, on mountains [g] in Piedmont [h]. On old walls and buildings in many parts of England [i]. The only certain authority, however, on which this ſpecies reſts, is that of Linnæus. That which occurs on old walls in England ſeems to be the common Pink of the gardens, D. Caryophyllus [k].

It flowers in may and june.

22. Root woody, perennial, putting forth many ſtems of a finger's length, having three joints. Leaves on the ſtem linear, bluntiſh, flat; root-leaves in tufts, linear-lanceolate. Inner calycine ſcales only half the length of the outer ones. Corolla large; petals the length of the calyx, round, with numerous very ſhort teeth, and the throat a little villoſe [l]. The leaves are ſometimes obtuſe, ſometimes acute [m].

Native of the Alps; Sileſia, Auſtria, Stiria, Siberia, in rough, ſtony places; flowering in june and july.

23. Root perennial. Lower leaves copious, erect, in an imbricate tuft, acuminate, like thoſe of Thrift. Stems few, a ſpan in height, having four very ſimple joints, with ſmaller leaves, the uppermoſt very ſmall, ariſing from a perfoliate ſheath. Calycine ſcales broad, ovate, acute; the two pairs remote. Border of the corolla ſhorter by half than the tube of the calyx, and rounded. Only one flower uſually on the ſtem: but ſometimes a ſecond from the upper axil [n].—Leaves ſhort, narrow, toothletted. Petals emarginate, crenate [o]. Stems decumbent, not proſtrate; there are ſeveral flowers on a ſtem, it ſhould be removed therefore to the third ſection; the flowers are inodorous.

Native of the Alps; the South of France, Auſtria, Carniola, &c. Dr. Smith gathered it on the limeſtone rocks oppoſite the poſt-houſe on mount Cenis, in auguſt 1787 [p]. It flowers in june and july.

Cultivated in 1732, by James Sherard, M.D. [q]. Mr. Miller ſeems to confound it with D. deltoides.

24. Stalks eighteen inches and more in height, white, round, ſmooth, jointed, woody, branched. Leaves glaucous, an inch and half long, narrow, rigid, mucronate. Calyx echinate. Petals pale purple, ſtriated, a little beyond the middle marked with a dark red dotted line, forming a ring, below which they are lanuginous; they are cut about the edge [r]. Native of the iſland of Candia.

25. Stem twiſted, two feet high, woody, brittle, hard, covered with a dark, cloven bark. Leaves an inch long, and three or four lines broad, obtuſe, fleſhy, brittle, bitter as gall, growing in tufts. Flowers commonly ſolitary, but ſometimes ſeveral together. Petals an inch and half long. Native of the iſland of Seriphos in the Levant [s].

It is only a variety of the preceding, with ſhorter leaves a little broader, and blunt at the end [t].

26. Stem ſhrubby, with a lacerated chinky bark, very much branched, the ſmall branches with cloſe tufts of leaves at the ends: flowering-branches elongated, round and ſmooth, with two or three pairs of leaves only, much ſhorter than the internodes. Leaves very narrow, mucronate-pungent, channelled, with a ſmooth even edge. Flowers two or three at the tops of the branchlets, pedicelled, ſmall. Calycine ſcales blunt, ſcarcely ſtriated, membranaceous round the edge, and at the top; tube ſtriated, with ſharp teeth, and not membranaceous about the edge. Petals crenate and gaſhed. Styles capillary, ſtanding out.

Native of the iſland of Candia, where it was obſerved by Tournefort [u].

27. The ſtems are full of alternate branches. The ſtem-leaves are connate and ſheathing at the baſe, crowded, and covering the branches with their ſheaths: the leaves on the branches are ſlightly connected with diſtant ſheaths: all are ſtattiſh, acuminate, and ſomewhat prickly. The peduncles ariſe from the ends of the lateral branchlets: the pedicels ſuſtain from one to three flowers. Calycine

ſcales four, lanceolate, a little ſhorter than the calyx: petals quite entire, with the lamina of the ſame length with the claw. Native of Spain, on the coaſt [r].—It flowers from auguſt to october: and was introduced in 1781, by Monſ. Thouin [s].

This not being more ſhrubby than many others, accounted by Linneus to be herbaceous, ought to be placed with thoſe ſpecies, to which it is, in other reſpects, naturally allied [t], namely at the end of the ſecond diviſion after n. 20.—Virgineus, n. 23. ſhould alſo be in the ſame ſection or diviſion, after attenuatus & pungens. Cæſius, n. 13. ſhould be removed into the third ſection, with alpinus, & arenarius [u].

28. Plant a ſpan in height. Root woody. Root-leaves in a tuft, linear-ſubulate. Stems ſeldom two-flowered, ſmooth. Tube of the calyx cylindric, with four ovate, ſharp ſcales at the baſe. Petals pale purple. It is diſtinguiſhed from *D. pungens* by the calycine ſcales, and the ſtems being herbaceous; from all the other ſpecies by the linear ſhape of the leaves. There is a variety with roundiſh petals, white, and red. Native of Aragon [x].

29. Root perennial, thickiſh, and ſomewhat branched. Stem herbaceous, a foot high. Leaves lanceolate, glaucous; thoſe next the root obtuſe; on the ſtem acute, recurved. Flowers paniculed. Calycine ſcales ſix, ſometimes eight, ſeldom four, awl-ſhaped, dilated at bottom, membranaceous, a little ſhorter than the tube of the calyx. Petals yellowiſh, with a few hairs and red dots within at bottom; the claws are the length of the calyx. Filaments filiform, a little longer than the calyx. Styles ſwelling at the baſe, ſcarcely the length of the ſtamens.

Native of mount Libanus [y].

This belongs to the firſt ſection.

30. This plant grows in a tuft. The leaves are acute, ſmooth, and half an inch long. Flowers ſeſſile, ſolitary. Calyx the length of the leaves, ſmooth, ſtriated: ſcales ſix, oblong, acuminate, ſhorter than the flower, the outer ones ſmaller. Petals toothed [z].]

PROPAGATION AND CULTURE.

1. *D. barbatum*, or *Sweet-William*.—Of Sweet-Williams there is a great variety of different colours, which are ſingle, and three or four with double flowers.

Some of the ſingle flowers have very rich colours, which frequently vary in thoſe of the ſame bunch; there are others with fine variegated flowers, and others whoſe middles are of a ſoft red, bordered with white, which are called Painted Ladies; but where perſons are deſirous to preſerve any of theſe varieties in perfection, the beſt flowers of each ſhould be particularly marked, and no other permitted to ſtand near them, leſt their farina ſhould impregnate them, which would cauſe them to vary.

That which is called the Painted Lady Sweet-William, is a very beautiful variety; the ſtalks of this do not riſe ſo high as moſt of the others; the bunches of flowers are larger, and produced more in the form of an umbel, the flowers ſtanding equal in height, make a better appearance: there are others whoſe ſtalks riſe three feet high, and the flowers of a very deep red or ſcarlet colour. Theſe all flower at the ſame time with the Carnations, which renders them leſs valuable, becauſe they have no ſcent.

[Theſe plants muſt be renewed annually, to have them in perfection; for though they are perennial, yet they are ſubject to decay. If there are not ſo many varieties as of the Pink and Carnation, it is becauſe this ſpecies has not attracted ſo much attention.]

The ſingle ſorts are generally propagated by ſeeds, which muſt be ſown the latter end of march or the beginning of april, in a bed of light earth, and in june they will be fit to tranſplant out; at which time prepare ſome beds ready for them, and ſet them at ſix inches diſtance every way: in theſe beds they may remain till michaelmas, when they may be tranſplanted into the borders of the pleaſure-garden or wilderneſs. Theſe will flower the next year in june, and in auguſt perfect their ſeeds, which ſhould be ſaved from the beſt-coloured flowers for a ſupply.

They may alſo be propagated by ſlipping their roots at michaelmas; but this is ſeldom practiſed, becauſe ſeedling roots always blow the ſtrongeſt, and produce new varieties.

Double Sweet-Williams are propagated by [cuttings, pipings, or] layers, as Pinks and Carnations: they love a middling ſoil, not too light, nor too heavy or ſtiff, nor too much dunged, which very often occaſions their rotting. Theſe continue flowering a long time, and are extremely beautiful, eſpecially the Mule, which produces two full blooms of flowers, one in june, and the other in july: it is very ſubject to canker and rot, eſpecially if planted in a ſoil too wet or dry, or if watered with ſharp ſpring water. Theſe flowers planted in pots, are very proper to adorn court-yards.

D. Caryophyllus. Carnation.

Theſe flowers are propagated either from ſeeds (by which new flowers are obtained), or from layers, for the increaſe of thoſe ſorts which are worth maintaining; but I ſhall firſt lay down the method of propagating them from ſeeds, which is thus:

Having obtained ſome good ſeeds, either of your own ſaving, or from a friend that you can confide in; about the middle of april, prepare ſome pots or boxes, according to the quantity of ſeed you have to ſow, filled with freſh light earth mixed with rotten neats dung, which ſhould be well incorporated together; then ſow your ſeeds thereon, but not too thick, covering it about a quarter of an inch with the ſame light earth, placing the pots or caſes ſo as to receive the morning ſun only till eleven of the clock, obſerving alſo to refreſh the earth with water as often as it may require. In about a month's time your plants will come up, and if kept clear from weeds, and duly watered, will be fit to tranſplant about the end of july; at which time prepare ſome beds (of the ſame ſort of earth as was directed to ſow them in) in an open airy ſituation, in which plant them at about three inches ſquare, obſerving to water and ſhade them till they have taken new root, obſerving to keep them clear from weeds; in theſe beds they may remain until the end of auguſt, by which time they will have grown ſo large as almoſt to meet each other; then prepare ſome more beds of the like good earth, in quantity proportionable to the flowers you have raiſed, in which plant them at ſix inches diſtance each way, and not above four rows in each bed, for the more conveniently laying ſuch of them as may prove worth preſerving, for in theſe beds they ſhould remain to flower.

The alleys between theſe beds ſhould be two feet wide, that you may paſs between the beds to weed and clean them. If the ſeaſon ſhould prove very dry at this time, they ſhould not be tranſplanted till there is ſome rain; ſo that it may happen to be the middle, or latter end of ſeptember ſome years, before there may be wet enough to moiſten the ground for this purpoſe; but if there is time enough for the plants to get good root before the froſt comes on, it will be ſufficient. If the winter ſhould prove ſevere, the beds ſhould be arched over with hoops, that they may be covered with mats, otherwiſe many of the plants may be deſtroyed, for the good flowers are not ſo hardy as the ordinary ones. There will be no other culture wanting to theſe, but to keep them clean from weeds, and when they ſhoot up their ſtalks to flower, they muſt be ſupported by ſticks to prevent their breaking. When your flowers begin to blow, you muſt look over them to ſee which of them proffer to make good flowers, which as ſoon as you diſcover, you ſhould lay

r Linn. mant. s Hort. kew. t Smith.
u Ibid. x D'Aſſo. y Billardiere.
z Vahl.

lay down all the layers upon them; thoſe which are well marked, and blow whole without breaking their pods, ſhould be reſerved to plant in borders, to furniſh you with ſeed; and thoſe which burſt their pods, and ſeem to have good properties, ſhould be planted in pots, to try what their flowers will be, when managed according to art; and it is not till the ſecond year that you can pronounce what the value of a flower will be, which is in proportion to the goodneſs of its properties.

Having made choice of ſuch of your flowers as promiſe well for the large ſort, theſe you ſhould mark ſeparately for pots, and the round whole blowing flowers for borders; you ſhould pull up all ſingle flowers, or ſuch as are ill-coloured, and not worth preſerving, that your good flowers may have the more air and room to grow ſtrong; theſe having been laid at a proper ſeaſon, as ſoon as they have taken root, which will be ſome time in auguſt, they ſhould be taken off, and planted out, thoſe that blow large, in pots, and the others in borders.

Of late years the whole-blowing flowers have been much more eſteemed than thoſe large flowers which burſt their pods, but eſpecially thoſe round flowers which have broad ſtripes of beautiful colours, and round Roſe leaves, of which kinds there have been a great variety introduced from France within theſe few years; but as theſe French flowers are extremely apt to degenerate to plain colours, and being much tenderer than thoſe which are brought up in England, there are not ſuch great prices given for the plants now, as have been a few years paſt; from the preſent taſte for theſe whole-blowing Flake flowers, many of the old varieties, which had been turned out of the gardens of the floriſts many years ago, to make room for the large flowers, which were then in faſhion, have been received again; and large prices have been paid for ſuch flowers as ſome years before were ſold for one ſhilling a dozen, or leſs, which is a ſtrong proof of the variableneſs of the fancies of the floriſts.

But I ſhall now proceed to give ſome directions for propagating theſe flowers by layers, and the neceſſary care to be taken in order to blow them fair and large.

The beſt ſeaſon for laying theſe flowers is in june, as ſoon as the ſhoots are ſtrong enough for that purpoſe, which is performed in the following manner: after having ſtripped off the leaves from the lower part of the ſhoot intended to be laid, make choice of a ſtrong joint about the middle part of the ſhoot, not too near the heart of the ſhoot, nor in the hard part next the old plant; then with your pen-knife make a ſlit in the middle of the ſhoot from the joint upwards half way to the other joint, or more, according to their diſtance; then with your knife cut the tops of the leaves, and alſo cut off the ſwelling part of the joint where the ſlit is made, ſo that the part ſlit may be ſhaped like a tongue; for if that outward ſkin is left on, it would prevent their puſhing out roots; then having looſened the earth round the plant, and, if need be, raiſed it with freſh mould, that it may be level with the ſhoot intended to be laid down, leſt by the ground being too low, by forcing down the ſhoot, you ſplit it off; then with your finger make a hollow place in the earth, juſt where the ſhoot is to come, and with your thumb and finger bend the ſhoot gently into the earth, obſerving to keep the top as upright as poſſible, that the ſlit may be open; and being provided with forked ſticks for that purpoſe, thruſt one of them into the ground, ſo that the forked part may take hold of the layer, in order to keep it down in its proper place; then gently cover the ſhank of the layer with the ſame ſort of earth, giving it a gentle watering to ſettle the earth about it, obſerving to repeat the ſame as often as is neceſſary, in order to promote their rooting. In about five or ſix weeks after this, the layers will have taken root ſufficient to be tranſplanted; againſt which time be provided with proper earth for them, which may be compoſed after the following manner:

Make choice of ſome good up-land paſture, or a common that is of a hazel earth, or light ſandy loam; dig from the ſurface of this your earth about eight inches deep, taking all the turf with it; let this be laid in a heap to rot and mellow for one year, turning it once a month, that it may ſweeten; then mix about a third part of rotten neats dung, or for want of that, ſome rotten dung from a Cucumber or Melon-bed; let this be well mixed together, and if you can get it time enough beforehand, let them lie mixed ſix or eight months before it is uſed, turning it ſeveral times, the better to incorporate their parts.

Obſerve, that although I have mentioned this mixture as the beſt for theſe flowers, yet you muſt not expect to blow your flowers every year equally large in the ſame compoſition; therefore ſome people alter their compoſitions every year in this manner, viz. one year they mix the freſh earth with neats dung, which is cold; the next year with rotten horſe dung, which is of a warmer nature, adding thereto ſome white ſea ſand to make the earth lighter.

But, for my part, I ſhould rather adviſe the planting two or three layers of each of the beſt kinds in a bed of freſh earth not over dunged, which plants ſhould only be ſuffered to ſhew their flowers, that you may be ſure they are right in their kind and colours; and when you are ſatisfied in that particular, cut off the flower-ſtems, and do not ſuffer them to ſpend the roots in blowing, by which means you will ſtrengthen your layers. And it is from theſe beds I would make choice of ſome of the beſt plants for the next year's blowing, always obſerving to have a ſucceſſion of them yearly, by which means you may have every year fine flowers, provided the ſeaſon proves favourable: for it is not reaſonable to ſuppoſe, that the layers taken from ſuch roots as have been exhauſted in producing large flowers, and have been forced by art to the utmoſt of their natural ſtrength, ſhould be able to produce flowers equally as large as their mother root did the year before, or as ſuch layers as are freſh from a poorer ſoil, and in greater health can do. But this being premiſed, let us proceed to the planting of theſe layers, which, as I ſaid before, ſhould be done in auguſt, or the beginning of ſeptember.

The common method uſed by moſt floriſts is, to plant their layers at this ſeaſon, two in each pot, the ſize of which pots are about nine inches over in the clear at the top; in theſe pots they are to remain for bloom; and therefore in the ſpring of the year, they take off as much of the earth from the ſurface of the pots as they can, without diſturbing their roots, filling the pots up again with the ſame good freſh earth as the pots were before filled with. But there is ſome difficulty in ſheltering a great quantity of theſe flowers in winter, when they are planted in ſuch large pots, which in moſt winters they will require, more or leſs; my method therefore is, to put them ſingly into halfpenny pots in autumn, and in the middle or latter end of october, to ſet theſe pots into a bed of old tanner's bark, which has loſt its heat, and cover them with a common frame, ſuch as is uſed for raiſing Cucumbers and Melons; and in two of theſe frames, which contain ſix lights, may be ſet a hundred and fifty of theſe pots: in theſe frames you may give them as much free air as you pleaſe, by taking off the lights every day when the weather is mild, and putting them on only in bad weather and great rains; and if the winter ſhould prove ſevere, it is only covering the glaſſes with mats, ſtraw, or Peaſe-haulm, ſo as to keep out the froſt, which will effectually preſerve your plants in the utmoſt vigour.

In the middle or latter end of february, if the ſeaſon is good, you muſt tranſplant theſe layers into pots for their bloom, the ſize of which ſhould be about eight inches over at the top in the clear; in the doing of which, obſerve to put ſome pot-ſherds or oyſter-ſhells over the holes in the bottoms of the pots, to keep the earth from ſtopping them, which would

would detain the water in the pots to the great prejudice of the flowers: then fill theſe pots about half way with the ſame good compoſt as was before directed, and ſhake the plants out of the ſmall pots with all the earth about the roots; then with your hands take off ſome of the earth round the outſide of the ball, and from the ſurface taking off the fibres of the roots on the outſide of the ball of earth; then put one good plant exactly in the middle of each pot, ſo that it may ſtand well as to the height, i. e. not ſo low as to bury the leaves of the plant with earth, nor ſo high, that the ſhank may be above the rim of the pot; then fill the pot up with the earth before-mentioned, cloſing it gently to the plant with your hands, giving it a little water, if the weather is dry, to ſettle the earth about it; then place theſe pots in a ſituation where they may be defended from the north wind, obſerving to give them gentle waterings, as the ſeaſon may require.

In this place they may remain till the middle or end of april, when you ſhould prepare a ſtage of boards to ſet the pots upon, which ſhould be ſo ordered as to have little ciſterns of water round each poſt, to prevent the inſects from getting to your flowers in their bloom, which, if they are ſuffered to do, will mar all your labour, by deſtroying all your flowers in a ſhort time; the chief and moſt miſchievous inſect in this caſe is, the earwig, which will gnaw off all the lower parts of the petals of the flowers, which are very ſweet, and thereby cauſe the whole flower to fall to pieces; but ſince the making one of theſe ſtages is ſomewhat expenſive, and not very eaſy to be underſtood by ſuch as have never ſeen them, I ſhall deſcribe a very ſimple one, which I have uſed for ſeveral years, which anſwers the purpoſe full as well as the beſt and moſt expenſive one can do: firſt, prepare ſome common flat pans, about fourteen or ſixteen inches over, and three inches deep; place theſe two and two oppoſite to each other, at about two feet diſtance, and at every eight feet lengthways, two of theſe pans; in each of theſe whelm a flower-pot, which ſhould be about ſix inches over at the top, upſide-down, and lay a flat piece of timber, about two feet and a half long, and three inches thick, croſs from pot to pot, till you have finiſhed the whole length of your ſtage; then lay your planks lengthways upon theſe timbers, which will hold two rows of planks for the ſize pots which were ordered for the Carnations; and when you have ſet your pots upon the ſtage, fill the flat pans with water, always obſerving, as it decreaſes in the pans, to replenith it, which will effectually guard your flowers againſt inſects; for they do not care to ſwim over water, ſo that if by this, or any other contrivance, the paſſage from the ground to the ſtage, on which the pots are placed, is defended by a ſurface of water three or four inches broad, and as much in depth, it will effectually prevent theſe vermin from getting to the flowers.

This ſtage ſhould be placed in a ſituation open to the ſouth-eaſt, but defended from the weſt winds, to which theſe ſtages muſt not be expoſed, leſt the pots ſhould be blown down by the violence of that wind, which is often very troubleſome at the ſeaſon when theſe flowers blow; indeed they ſhould be defended by trees at ſome diſtance, from the winds of every point; but theſe trees ſhould not be too near the ſtage, nor by any means place them near walls, or tall buildings, for in ſuch ſituations the ſtems of the flowers will draw up too weak. About this time, viz. the middle of april, your layers will begin to ſhoot up for flower; you muſt therefore be provided with ſome ſquare deal ſticks, about four feet and a half long, which ſhould be thicker toward the bottom, and planed off taper at the top; theſe ſticks ſhould be carefully ſtuck into the pots as near as poſſible to the plant, without injuring it; then with a ſlender piece of baſs mat, faſten the ſpindle to the ſtick to prevent its being broken: this you muſt often repeat, as the ſpindle advances in height, and alſo obſerve to pull off all ſide ſpindles as they are produced, and never let more than two ſpindles remain upon one root, nor above one, if you intend to blow exceeding large. Toward the beginning of june your flowers will have attained their greateſt height, and their pods will begin to ſwell, and ſome of the earlieſt begin to open on one ſide: therefore obſerve to let it open in two other places at equal angles; this muſt be done ſo ſoon as you perceive the pod break, otherwiſe your flower will run out on one ſide, and be in a ſhort time paſt recovering, ſo as to make a complete flower, and in a few days after the flowers begin to open, you muſt cover them with glaſſes which are made for that purpoſe, in the following manner:

Upon the top of the glaſs, exactly in the center, is a tin collar, or ſocket, about three fourths of an inch ſquare, for the flower-ſtick to come through: to this ſocket are ſoldered eight ſlips of lead at equal diſtances, which are about ſix inches and a half long, and ſpread open at the bottom about four inches aſunder; into theſe ſlips of lead are faſtened ſlips of glaſs, cut according to the diſtances of the lead, which, when they are fixed in, are bordered round the bottom with another ſlip of lead quite round, ſo that the glaſs has eight angles, with the ſocket in the middle, and ſpread open at the bottom about eleven inches wide.

When your flowers are open enough to cover with theſe glaſſes, make a hole through your flower-ſtick, exactly to the height of the under part of the pod, through which put a piece of ſmall wire about ſix inches long, making a ring at one end of the wire to contain the pod, into which ring fix the ſtem of the flower; then cut off all the thorns of baſs, and thruſt the ſtem of the flower ſo far from the ſtick, as may give convenient room for the flower to expand without preſſing againſt the ſtick; to which diſtance you may fix it, by turning your wire ſo as not to draw back through the hole: then make another hole through the ſtick, at a convenient diſtance above the flower, through which put a piece of wire, an inch and a half long, which is to ſupport the glaſſes from ſliding down upon the flowers; and be ſure to obſerve, that the glaſſes are not placed ſo high as to admit the ſun and rain under them to the flowers, nor ſo low as to ſcorch their leaves with the heat. At this time alſo, or a few days after, as you ſhall judge neceſſary, cut ſome ſtiff paper, cards, or ſome ſuch thing, into collars about four inches over, and exactly round, cutting a hole in the middle of it about three fourths of an inch diameter, for the bottom of the flower to be let through; then place theſe collars about them, to ſupport the petals of the flower from hanging down; this collar ſhould be placed within-ſide the calyx of the flower, and ſhould be ſupported thereby; then obſerve from day to day what progreſs your flowers make; and if one ſide comes out faſter than the other, turn the pot about, and ſhift the other ſide towards the ſun; and alſo if the weather proves very hot, ſhade the glaſſes in the heat of the day with Cabbage leaves, &c. to prevent their being ſcorched, or forced out too ſoon; and when the middle pod begins to riſe, take out the calyx thereof with a pair of nippers made for that purpoſe; but this ſhould not be done too ſoon, leſt the middle part of the flower ſhould advance too high above the ſides, which will greatly diminiſh the beauty of it: and you ſhould alſo obſerve whether there are more leaves in the flower than can properly be expanded for want of room; in which caſe you ſhould put out ſome of the lowermoſt or moſt unlikely leaves to ſpread, drawing out and expanding the others at the ſame time: and when your flowers are fully blown, if you cut them off, put on a freſh collar of ſtiff paper, which ſhould be cut exactly to the ſize of the flower, that it may ſupport the petals to their full width, but not to be ſeen wider than the flower in any part: when this is put on, draw out the wideſt leaves to form the outſide of the flower, which although they ſhould be in the middle, yet by removing the other leaves they may be drawn

down, and ſo the next longeſt leaves upon them again, that the whole flower may appear equally globular without any hollow parts. In the doing of this, ſome floriſts are ſo curious as to render an indifferent flower very handſome; and on this depends, in a great meaſure, the ſkill of the artiſt to produce large fine flowers.

During the flower ſeaſon, particular care ſhould be taken not to let them ſuffer for want of water, which ſhould by no means be raw ſpring water; nor do I approve of compound waters, ſuch as are enriched with various ſorts of dung; but the beſt and moſt natural water is that of a fine ſoft river; next to that is pond water, or ſtanding water; but if you have no other than ſpring water, it ſhould be expoſed to the ſun and air two days before it is uſed, otherwiſe it will give the flowers the canker and ſpoil them.

The directions here given are chiefly for the management of thoſe large Carnations, which require the greateſt ſkill of the floriſts, to have them in perfection; but of late years theſe have not been ſo much in eſteem as formerly, and thoſe flowers which do not break their pods, and are termed whole Blowers, have now the preference. Theſe are generally planted in pots, and treated in the ſame way as the large flowers, but do not require ſo much trouble to blow them: all that is neceſſary to be done for theſe, is to faſten their ſtems up to flower-ſticks to prevent their being broken, and to take off the pods which proceed from the ſide of the ſtalks, leaving only the top bud to flower, if they are intended to be large and fair; and when the flowers begin to open, if they are ſcreened from the ſun in the heat of the day, and alſo from wet, they will continue much longer in beauty.

But although the moſt valuable of theſe flowers are uſually planted in pots, and thus carefully treated, yet many of theſe whole blowing flowers may be planted in beds, or borders of the flower-garden, where they are ſome of the principal ornaments during their continuance in flower, which is from the beginning of july till the middle of auguſt, eſpecially if the ſeveral colours are properly intermixed; for the Flakes and Bizarrs ſhould be intermixed with the Picquettes, and not planted ſeparate, unleſs where they are deſigned for ſaving the ſeeds; in which caſe, thoſe which are the fineſt of each ſort, ſhould be planted in beds at a diſtance from each other, eſpecially where perſons are deſirous to keep them diſtinct; for where the ſorts are blended together, there will be an admixture of their farina, ſo that the ſeeds will vary, and not produce the particular kinds; though I do not remember ever to have ſeen any Flake flowers ariſe from ſeeds of the Picquettes, nor vice verſâ.

The flowers which are planted in the full ground, generally produce ſeeds better than thoſe in pots; but whoever propoſes to raiſe a ſupply of new flowers from ſeeds, muſt always obſerve to ſave the beſt of their ſeedling flowers for this purpoſe; for it is well known, that after any of theſe flowers have been a few years propagated by layers, they become barren, and do not ſeed; which is alſo the caſe with moſt other plants which are propagated by ſlips, layers, or cuttings; ſo that the young plants which have been newly obtained from ſeeds, are always the moſt productive of ſeeds: the plants which are propagated by layers or ſlips, will always continue to produce the ſame flowers, ſo that when a fine variety is obtained, it is this way propagated and maintained; but all the new varieties come from ſeeds, ſo that all thoſe who are curious in theſe flowers, annually ſow their ſeeds.

[Carnations may alſo be increaſed by cuttings and pipings as Pinks are, but not ſo ſucceſsfully in general as by layers, unleſs the operation is performed on a hot-bed under glaſſes. The cuttings for piping ſhould have two joints, ſhould be thrown into water a few minutes, and planted not more than half an inch deep. They are to be gently watered, and to continue open till their leaves are dry before they are covered. After this, they are to be kept moiſt till they have rooted, to have only the morning ſun, and air is to be given them occaſionally. But with all this care, ſucceſs will at leaſt be uncertain; or at beſt, many of the cuttings will frequently periſh.]

Pinks.

The common Pinks are propagated either by ſeeds, which is the way to obtain new varieties; or by layers, as is practiſed for Carnations; or by ſlips, or pipings as they are commonly called, which, if carefully managed, will take root very well.

If they are propagated by ſeeds, care ſhould be taken in the choice of them, and only the ſeeds of the beſt ſorts ſaved, where perſons are curious to have the fineſt flowers. Theſe ſeeds may be ſown in the ſpring, and the plants afterwards treated in the ſame manner as has been directed for the Carnation; with this difference only, that as the Pinks are leſs tender, they may be more hardily treated. Thoſe which are propagated by layers, muſt be alſo managed as the Carnation. The old Man's Head and painted Lady Pinks are commonly propagated this way, but moſt of the other ſorts are increaſed from cuttings, or pipings.

The beſt time for this is about the end of july, when, if there ſhould happen any rain, it will be of great ſervice; but if the weather ſhould prove dry, the cuttings or pipings will require to be watered every other day, until they have taken root. They ſhould be planted in a ſhady border, and the ground ſhould be dug well, and all the clods broken, and if no rain falls, it ſhould be well ſoaked with water a few hours before they are planted; then they ſhould be taken from the plants, and all their lower leaves ſtripped off, and planted as ſoon as poſſible after, for if they are ſuffered to lie long after they are taken from the plants, they will wither and ſpoil; theſe need not be planted at a greater diſtance than three inches ſquare, and the ground muſt be cloſed very hard about them; then they muſt be well watered, and this muſt be repeated as often as is found neceſſary, till they have taken root; after which they will require no other care but to keep them clean from weeds till autumn, when they ſhould be tranſplanted to the borders of the flower-garden where they are to remain. There are ſome who perform this operation later in the ſeaſon than is here directed; but thoſe plants are never ſo ſtrong nor flower ſo well, as thoſe which are early planted.

[The time moſt proper for piping will vary with the ſeaſon, but it ſhould always be done immediately before or during the bloom, or indeed as ſoon as the young ſhoots are of a ſufficient length for the purpoſe; that is, to form pipings from two to three inches in length. The ſtriking will be much facilitated by covering the beds or pots with glaſſes, after having given them a good watering; not taking off the glaſſes till the cuttings or pipings begin to grow, but applying the water, when neceſſary, round the outſide of the glaſſes. In a month or ſix weeks they will be rooted and grow, when they may be fully expoſed. The only difference between cuttings and pipings is, that the former are cut through a joint horizontally, and the latter are drawn out at the joint from their ſockets, ſo that they leave a hollow like a pipe, and thence derive their name.

Pinks may alſo be increaſed, by ſlipping off the young ſhoots from the ſides of the main ones, any time in the ſpring from february to april. The ſlips ſhould be from three or four to ſix or eight inches in length.]

15. D. chinenſis. China or Indian Pink.—The China Pink is generally ſuppoſed an annual plant, becauſe the plants which are raiſed from ſeeds flower and produce ripe ſeeds the ſame ſeaſon, ſo their roots are not often preſerved; but where they are planted on a dry ſoil, they will continue two years, and the ſecond year will produce a greater number of flowers than the firſt. There are a great

variety of very rich colours in theſe flowers, which annually vary when raiſed from ſeeds. The double flowers of this ſort are moſt eſteemed, though the colours of the ſingle are more diſtinct and beautiful; for the multiplicity of petals in the double flowers, in a great meaſure, hides the deep ſhades, which are toward the lower part of the petals.

Theſe plants are propagated by ſeeds, which ſhould be ſown upon a gentle hot-bed about the beginning of april; this moderate heat is only intended to forward the vegetation of the ſeeds, therefore when the plants come up, they muſt have a large ſhare of air admitted to them, to prevent their drawing up weak; and as ſoon as the weather will permit, they muſt be expoſed to the open air; in about three weeks or a month after, the plants will be fit to remove; then they ſhould be carefully taken up with good roots, and planted in a bed of rich earth, at about three inches aſunder, being careful to ſhade them from the ſun till they have taken new root, and in dry weather they muſt have water three or four times a week. The farther care is to keep them clean from weeds till the end of may, at which time they may be tranſplanted to the places where they are deſigned to remain for flowering, when they may be taken up with large balls of earth to their roots, ſo as ſcarcely to feel their removal, eſpecially if it happens to rain at that time.

As theſe plants do not grow large, ſo when they are planted ſingly in the borders of the flower-garden, they do not make ſo fine an appearance, as where they are planted by themſelves in beds; or if they are planted in ſmall clumps, of ſix or eight roots in each, where the flowers being of different colours, ſet off each other to advantage.

Thoſe who are curious in theſe flowers, take particular care in ſaving their ſeeds, for they never permit any ſingle flowers to ſtand among their double, but pull them up as ſoon as they ſhew their flowers, and alſo draw out all thoſe which are not of lively good colours; where this is obſerved, the flowers may be kept in great perfection; but where perſons have truſty friends, who live at ſome diſtance, with whom they can exchange ſeeds once in two or three years, it is much better ſo to do, than to continue ſowing ſeeds in the ſame place many years in ſucceſſion, and this holds true in moſt ſorts of ſeeds: but the great difficulty is to meet with an honeſt perſon of equal ſkill, who will be as careful in the choice of his plants for ſeed, as if he was to ſow them himſelf.

19. D. ſuperbus deſerves a place in every curious garden, on account of the elegance and delicious fragrance of the flowers. It grows naturally in a calcareous ſoil, and will thrive luxuriantly in a garden if chalk be mixed with the common mould, but not otherwiſe[t].

The other European ſorts are hardy, eaſily raiſed from ſeeds, and cultivated with little trouble; but the flowers being ſmall, and in general not having much ſcent, they are little noticed, except in botanic gardens; their beauty however, though loſt in the ſuperior blaze of Pinks and Carnations, is not inconſiderable; and they are peculiarly ornamental on walls and rock-work, and in dry, barren ſpots, where few plants will flouriſh.

The Cape Pink (n. 14.) is the only ſort which will not bear the open air in our climate.

24, 25, 26. The woody or ſhrubby Pinks are noble ornamental plants, and it is to be lamented that they are loſt to our gardens.

DIANTHUS ſaxifragus. See *Gypſophila*.

2. Dicera ſerrata.

Forſt. gen. 80. *flor. auſtral. n.* 227.

Elæocarpus Dicera. *Lin. ſuppl.* 266.

Styles four, leaves oppoſite cordate-ovate unequally ſerrate, racemes lateral compound.

DESCRIPTIONS, *&c.*

1. This is an elegant tree, bearing at the extremities of the branches abundance of leaves, which are alternate, oval or oval-oblong, bluntiſh, ſmooth, veined, bluntly ſerrate, petioled, with a double gland at

[t] Smith ſpicil.

[s] Linn. ſupp.

their base. Racemes axillary, simple, loose, solitary, the length of the leaves[b]. Flowers on very minute pedicels, nodding. Stamens sixteen when there are four, and twenty when there are five petals[c]. Linnæus remarked twenty stamens in the Ceylonese plant, and only eight in that from Java[d]. Pistil single. Fruit an oval berry? with a hard stone in it. It is preserved whilst unripe after the manner of Olives[e]. See *Elæocarpus ferratus*.

Native of New Zealand.

2. This agrees in the structure of the flower with the preceding, but it differs in the fruit.—Native of New Zealand[f]. See *Elæocarpus Dicera*.

DICHONDRA. (*From δις twice, and χονδρος, a grain, because two little grains succeed to each flower.*) *Forst. gen.* 40. *t.* 20. *Smith ic. ined.* 1. 8. *Juss.* 129. *Schreb. n.* 451.

Class. 5. 2. Pentandria Digynia.

Nat. order of *Asperifoliæ*. *Borragineæ*. Juss.

GENERIC CHARACTER.

Cal. five-leaved: *leaflets* obovate, netted-nerved, hairy without, smooth within, permanent.

Cor. monopetalous, inferior, rotate, subcampanulate, five-cleft, the length of the calyx.

Stam. *Filaments* five; subulate, spreading, placed alternately between the divisions of the corolla, and only half the length. *Anthers* roundish.

Pist. *Germ* two hairy. *Styles* two divaricate, setaceous, the length of the stamens, arising on the inside from the base of the germs. *Stigmas* capitate.

Per. *Capsules* two globular subhirsute, one-celled.

Seeds one in each cell, globular.

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* rotate, inferior. *Capsi.* dicoccous.

SPECIES.

1. Dichondra repens.

Forst. gen. 20. *fl. austral. n.* 134. *Smith ic. ined.* 1. 8. Sibthorpia evolvulacea. *Linn. suppl.* 288.

DESCRIPTION, *&c.*

Stem prostrate creeping branched round. *Leaves* alternate, petioled, erect, kidney-shaped, sometimes emarginate, above almost naked, below silky, radiate-veined: petioles round silky. *Flowers* small, rather nodding, on axillary filiform simple silky peduncles, scarcely the length of the petioles, and usually solitary. This was at first taken by Linnæus for a species of *Sibthorpia*, from which it differs both in class and order, and in having two capsules with a single seed in each, instead of a two-celled many-seeded capsule, which the *Sibthorpia* has. It is also very distinct from *Falkia*, which it resembles somewhat in the leaves.—The specimens from different countries differ in having the leaves naked above, or silky on both sides; also in the length of the petioles and peduncles; but these seem only to be varieties.

Mutis sent it to Linnæus from New Granada. Commerson found it at Buenos Ayres, and in the island of Mauritius. It is also known to be a native of Peru, Jamaica and New Zealand[g].

Dichotophyllum. See *Ceratophyllum*.

DICKSONIA. (*So named by Mons. L'Heritier, from Mr. James Dickson; who from his accurate knowledge in the Cryptogamia class, well deserves such an honour.*)

L'Herit. sert. angl. 30. *t.* 13.

Class. 24. 1. Cryptogamia Filices.

Nat. order of *Filices*, or *Ferns*.

GENERIC CHARACTER.

Fructifications kidney-shaped lying under the edge of the frond at the lower surface: outer valve formed of the substance of the leaf itself, inner membranaceous.

SPECIES.

1. Dicksonia arborescens. *Tree Dicksonia.*

L'Herit. sert. angl. 31. *t.* 13. *Ait. hort. kew.* 3. 469.

Fronds superdecompound villose, leaflets almost entire; stem arborous.

2. Dicksonia Culcita. *Shining-leaved Dicksonia.*

L'Herit. sert. angl. 31. *n.* 2. *Ait. hort. kew.* 3. 469.

Polypodium Barometz. *Lin. spec.* 1553?

Fronds superdecompound smooth: leaflets serrate.

DESCRIPTION, *&c.*

1. Found by Sir Joseph Banks and Dr. Solander in the island of St. Helena[h].—Introduced 1786, by Mr. Anthony Hove. It flowers most part of the winter[i].

2. Found in the island of Madeira, where it is called *Feila Brom*; and in the island of S. Miguel, one of the Azores, by Masson.—The inhabitants make pillows and cushions of the roots.

There is little doubt but that this plant and the *Barometz* or *Scythian Lamb* are one and the same, though they come from countries so remote. See *Philos. Transact. for* 1698. *n.* 247. *p.* 461.—and for 1725. *n.* 390. *p.* 353. It is figured in both places. Also *Dorthoug. diss.* 596. *Kempf. amœn.* 505, &c.[k]—Introduced 1779[l].

Diconangia. See *Itea*.

Dicranum. A genus in Cryptogamia Musci, *Schreb. n.* 1644. *Hedw. fund.* 2. *p.* 91. Comprehending also his Fissideus. It embraces several species of Mnium, Bryum and Hypnum, of Linnæus.

Dictamnus. See *Origanum*.]

DICTAMNUS. (*From δικτυον, deducere, Lin.* Δικταμος, Δικταμνος, *&c* Δικταμνον, *Theophr. Dioscor.* Fraxinella, *dimin. of Fraxinus, an Ash; from the form of the leaves.*)

Leaves ſimple, ſtem branching.]

DESCRIPTION, *&c.*

1. Root perennial, ſtriking deep into the ground, and the head annually increaſing in ſize. Stalks many, two or three feet high, [round, here and there ſlightly grooved, ſometimes ſubancipital, not branched, at bottom green and beſet with white hairs, ferruginous red towards the top, with reſinous glands. Leaves alternate, the larger above a foot in length, ſpreading out horizontally, aſcending towards the end; the midrib flat at top and edged on both ſides, convex beneath and hairy; leaflets from two to five pairs, with an odd one at the end, moſt of them alternate, except the top pair or two, ſeſſile or ſubſeſſile, except the end one, which is on a long winged petiole, ſmooth, ſtiff, oblique except the end one, ovate, acute, ſerrate, ſhining on both ſides, about two inches long and an inch wide. The whole ſomewhat reſembling an Aſh leaf.] Flowers in a long pyramidal looſe ſpike or raceme, nine or ten inches long: [the branches of the raceme alternate, with a bracte at the foot of each, one or two-flowered: there is alſo a ſhort, lanceolate, hairy bracte to each pedicel. The red glands are ovate, pedicelled, acuminate, and have white hairs interſperſed. Calyx deeply five-cleft; ſegments lanceolate, obtuſe, the three upper red, the two lower green. Corolla large and handſome, the common natural colour pale purple with dark purple veins, but varying to white, the four upper petals ſtand erect, and the genitals ſtretch out horizontally on the fifth, on and about the middle nerve at the back it has the ſame red glands as are on the pedicel. Filaments pale purple, concealing the germ and ſtyle, aſcending or turning up at the end, glandular eſpecially at top: anthers green. Germ covered with pedicelled glands; ſtyle with white hairs; ſtigma blunt, dark purple. To each flower ſucceeds a fruit conſiſting of five compreſſed capſules, ſpreading out like the points of a ſtar, rough with hairs and glandular tubercles, ending at top in a ſtraight line, with a ſhort upright tooth or proceſs at the inner end, and a long red one ſtretching out at the other. Within this ſkin is a cartilaginous ovate-oblong ſhell, obliquely truncate at top, deeply emarginate and cut out on the inner ſide for the reception of the receptacle, two-valved, one-celled, opening claſtically within. Seeds two according to Linnæus; Scopoli ſays, only one. Gærtner affirms that there are ſix or eight in a capſule, but that only one or two come to maturity. I have generally found two ripe ſeeds, without any veſtiges of more: ſometimes one has been abortive. They are pear-ſhaped, very ſmooth, black and ſhining.]

The whole plant, eſpecially when gently rubbed, emits an odour like that of lemon-peel, but when bruiſed it has ſomething of a balſamic ſcent. [This fine ſcent is ſtrongeſt in the pedicels of the flowers, which are covered with glands of a ruſty red colour, exſuding a viſcid juice or reſin, which exhales in vapour, and in a dark place may be ſeen to take fire.

Fraxinella is a native of Germany, France, Spain, Auſtria, and Italy.] It flowers with us at the end of may, and in june, and the ſeeds ripen in ſeptember. For its beauty and fine ſcent it deſerves a place in every good garden. [It was cultivated by Gerarde in 1596*, and is named by him *Baſtard* or *Falſe Dittany*. Parkinſon calls it *Falſe White Dittany*.

2. This reſembles the firſt ſpecies very nearly. The ſimple leaves are alternate, and like the leaflets of the preceding. The raceme is the ſame in both. It is a native of the Cape of Good Hope†.—The ſame with Calodendrum capenſe‡; which ſee.]

PROPAGATION AND CULTURE.

Fraxinella is propagated by ſeeds, which if ſown in the autumn ſoon after they are ripe, the plants will appear the following april: but when they are kept out of the ground till the ſpring, the ſeeds ſeldom ſucceed; or if they do grow, it is the following ſpring before the plants appear, ſo that a whole year is loſt. When the plants come up, they muſt be conſtantly kept clean from weeds; and in the autumn when their leaves decay, the roots ſhould be carefully taken up, and planted in beds at ſix inches diſtance every way; theſe beds may be four feet broad, and the paths between them two, that there may be room enough to paſs between the beds to weed them. In theſe beds the plants may ſtand two years, during which time they muſt be conſtantly kept clean from weeds: and if they thrive well, they will be ſtrong enough to flower: in the autumn they ſhould be carefully taken up, and planted in the middle of the borders of the flower-garden; where they will continue thirty or forty years, producing more ſtems of flowers in proportion to the ſize of the roots. All the culture theſe require, is to be kept clean from weeds, and the ground about them dug every winter.

DICTAMNUS CRETICUS. See *Origanum*.

DIDELTA. (*From δις, twice, and the capital Greek letter Δ; the receptacle having the form of a double delta, or double equilateral triangle.*)
L'Herit. ſtirp. nov. t. 28. Juſſ. gen. 182. Schreb. 1351.
Claſſ. 19. 3. Syngeneſia Polygamia Fruſtranea.
Nat. order of Compound flowers.—*Corymbifera*. Juſſ.

GENERIC CHARACTER.

CAL. *common* double, permanent: *outer* three-leaved or three-parted, umbilicated at the back; *leaflets* cordate, acuminate, much expanded, tomentoſe-hoary above: *inner* placed on the diſk of the outer, ſhorter, compoſed of eleven or twelve *leaflets*, which are linear-lanceolate, very acute, ſerrate-prickly, one-nerved, ſpreading, five or ſix alternately ſhorter by half than the others; the twelfth often wanting.

COR. *compound* radiated. *Corollets hermaphrodite* numerous, ſhorter than the calyx; barren in a deltoid diſk, *fertile* in the outer triangles of the receptacle. *Females* eleven or twelve in the ray, each oppoſite to one of the calycine leaflets, and double the length of the calyx. *Proper* in both hermaphrodites funnel-ſhaped, half-five-cleft; *border* five-parted, linear, acute, patulous, revolute, brown at the tip: *female* ligulate, four or three-toothed, three-furrowed, tubular at the baſe, ſpreading.

STAM. in both hermaphrodites; *filaments* five, capillary, very ſhort, inſerted into the tube; *anthers* cylindric, tubular, five-toothed, brown at the tip, the length of the corollet. In the *females* the rudiment of one ſtamen inſerted at the top of the tube.

PIST. in the perfect hermaphrodites *germ* inferior, immerſed in the receptacle, oblong, compreſſed, crowned with a thin, ſhort *pappus* or *down*, like the eye-laſhes. *Style* ſlender, finally ſtanding out. *Stigma* two-parted, ſubulate, revolute. In the barren hermaphrodites, *germ* roundiſh, very ſmall, immerſed; in other reſpects as in the fertile. *Females*, ſcarcely any rudiment of a germ.

RECEPT. deltoid, flat, honey-combed with labyrinthed membranes, *diſtinct* and finally reſolvable into four partial deltas or triangles; the central naked, barren; the ſide ones producing ſeeds, roughened with ſtiff brown briſtles, becoming hard and in ſeparating from each other becoming a

PERIC. *Nuts* three, bony, three-cornered, flatted, ſtiff-briſtly, from the outer triangles of the receptacle gaped and hardened, each retaining an outer leaf and the oppoſite inner calycine leaflets or one third part of the calyx, and many-celled.

SEEDS.

* Hort. kew.

† Linn. ſuppl. ‡ Swartz obſ.

SEEDS. Small kernels (*nucleoli*) as many as there were germs, but some abortive, oblong. *Down* simple, thin, short, stiffer than in the flower.

ESSENTIAL CHARACTER.

Cal. expanding; outer leafy. *Recept.* honey-combed, dividing into parts which retain the seeds. *Down* chaffy, many-leaved.

SPECIES.

1. Didelta carnosa. *Succulent-leaved Didelta.*
Ait. hort. kew. 3. 256.
D. tetragoniæfolia. *L'Herit. ſtirp. nov.* 55. *t.* 28.
Polymnia carnosa. *Lin. ſyſt.* 790. *ſuppl.* 384.
Leaves alternate lanceolate-oblong fleſhy.

2. Didelta ſpinoſa. *Oppoſite-leaved Didelta.*
Ait. hort. kew. 3. 256.
Polymnia ſpinoſa. *Lin. ſyſt.* 790. *ſuppl.* 384.
Leaves oppoſite ſomewhat ſtem-claſping ovate.

DESCRIPTIONS, *&c.*

1. This plant is ſomewhat fleſhy, and has the air of *Tetragonia*. Seed-leaves two, claſping, obovate, fleſhy, ſmooth. Stem herbaceous, very much branched, erect, round, eighteen inches in height: branches alternate, diffuſed, fleſhy, ſmooth, green, the thickneſs of a quill; the extreme branchlets woolly. Leaves alternate, ſeſſile, ſpreading, acute, attenuated at the baſe, quite entire, revolute, woolly above, beneath one-nerved, ſmooth, veinleſs, two or three inches long, ſix or eight lines broad, in the ſtove permanent. Flowers ſolitary, terminating, on long peduncles, ſcarcely nodding, yellow. Annual, but in the ſtove enduring ſome years, and becoming ſomewhat ſhrubby, which is frequently the caſe with ſome annual plants[a].

It is a native of the Cape, and was found there by Mr. Fr. Maſſon. It flowers in July, and was introduced in 1774[b].

2. This is very ſmooth; the leaves are broad, and the outer calyx is five-leaved.—This alſo is a native of the Cape, whence it was brought by Thunberg[c], and Fr. Maſſon. It flowers in June and July, and was introduced the ſame year with the former[d].

PROPAGATION AND CULTURE.

Theſe plants may be propagated both from ſeeds and cuttings, muſt have the protection of a dry ſtove or glaſs-caſe, and may be managed as other Cape plants.

Leaves ovate, hairy on both ſides, flowers ſolitary axillary, ſegments of the calyx awl-ſhaped, corollas obtuſe entire at top.

DESCRIPTIONS, *&c.*

Theſe are large plants, with alternate leaves, and flowers in ſpikes at the ends of the ſtem and branches. The firſt, and probably the ſecond and third ſpecies are biennial; the reſt are commonly ſaid to be perennial, though Miller affirms that they are all biennial except his *orientalis*. The eighth and ninth ſorts are certainly ſomewhat ſhrubby, and therefore perennial.

1. *Root* biennial. *Stem* three to ſix feet high, ſimple, upright, leafy, round, pubeſcent. *Leaves* alternate, ovate-acute, ſerrate, veiny, wrinkled, underneath whitiſh with pubeſcence, gradually leſſening to both ends; petioles ſhort, winged. *Flowers* in a long ſpike, nodding, imbricate, all directed the ſame way: peduncles one-flowered, pubeſcent, thickeſt at top. Calyx alſo pubeſcent. Corolla purple, the bellying part ſprinkled on the inſide with ſpots like little eyes, or elegantly mottled; upper ſegment entire and truncate; lower bent in: obtuſely lobed above and four-cleft, the lower ſegment ſomewhat longer. Filaments a little broader at top, crooked at bottom; anthers at firſt large, turgid, ovate, cloven almoſt to the baſe, yellowiſh and often ſpotted, afterwards changing both their form and ſituation in a ſingular manner: germ rather conical, very hairy; ſtigma bifid: nectary, a gland ſurrounding the baſe of the germ: the lowermoſt valve of the capſule ſplits in two. Seeds dark brown, truncate at both ends[a].

Leaves on footſtalks that half claſp the ſtem, ſcalloped with deep ſmall notches, and curiouſly reticulated with fleſhy veins on their under ſurface. The peduncles ariſe each from a lanceolate entire bractle half embracing the ſtem, and purpliſh towards the point[b].

Capſule ovate-pyramidal, ſubpubeſcent: valves, when it is ripe often gaping with a chink on the ſides. Receptacle fungous, convex on one ſide, ſlightly concave on the other, by means of an entire lamina united to the axis of the fruit, but not to the diſſepiment. Seeds nearly of a parallelopiped form, marked with a longitudinal groove on one ſide, ſprinkled on all ſides with hollow dots in rows, and of a ferruginous colour[c].

Native of Denmark, Germany, Switzerland, Britain, in ſandy and gravelly ſoils: near London it grows plentifully about Charlton wood, Norwood, &c. It flowers from june to auguſt.

The corolla is in general of a fine purple; but it varies into different ſhades of that colour, and is frequently white or cream colour. Parkinſon (parad. 381, 382. n. 2, 3.) mentions varieties with bluſh-coloured and orange-tawny flowers, as well as white, both large and ſmall, n. 4, 5. Some thinking Foxglove to be a fooliſh name, ſays Parkinſon, do call them *Finger-flowers*, becauſe they are like unto the fingers of a glove, the ends cut off.

The Digitalis purpurea or common purple Foxglove has long been conſidered as a plant poſſeſſed of very powerful virtues. A dram taken inwardly excites violent vomitings. It is certainly a very active medicine, and merits great attention; and it is ſingular that a plant ſo powerful in its operations ſhould not ſooner have been introduced into the modern materia medica. The country people in Somerſetſhire are ſaid to have long been in the habit of uſing it, in decoction, in fevers, to purge and vomit, which ſometimes ariſes to a ſuperpurgation. The Italians have a proverb concerning this plant, (by them called Aralda,) *Aralda tutte piaghe ſalda*, Foxgloves cures all ſores. Parkinſon ſays that it is effectual in the falling ſickneſs, if two handfuls of it be boiled in ale with four ounces of polypody of the oak, and the decoction drank by the patient: and that they who had laboured under that diſeaſe twenty-ſix years, ſo that they fell down twice or thrice every month, were perfectly reſtored by the uſe of this decoction; and did not fall into a fit for the ſpace of fourteen or fifteen months after. The dried leaves applied, or the juice made into an ointment, has been highly commended in ulcers, king's evil, *&c. &c.* as well as the bruiſed flowers alſo made into an ointment with freſh butter.

The diuretic effects of Foxglove, for which it is now ſo deſervedly celebrated, and on which account, as well as for its other powers, it is ſo much uſed in dropſical caſes, ſeems to have been firſt aſcertained by *Dr.* Withering. Yet he obſerves that it ſeldom ſucceeds in men of great natural ſtrength, tenſe fibre, warm ſkin, and florid complexion; or in a tight cordy pulſe. If the belly in aſcites be tenſe, hard, and circumſcribed, or the limbs in anaſarca be ſolid and reſiſting, we have but little hope. On the contrary, if the pulſe be feeble, or intermitting, the countenance pale, the lips livid, the ſkin cold, the ſwollen belly ſoft and fluctuating, the anaſarcous limbs readily pitting under preſſure of the finger, we may expect the diuretic effects to follow in a kindly manner.

In hydrothorax or water in the cheſt, ſtriking proofs are ſaid to have been afforded of the efficacy of Foxglove. The doſe of the dried leaves in powder is from one to three grains a day: but if a liquid medicine be preferred, a dram of the dried leaves is to be infuſed for four hours in half a pint of boiling water, adding to the ſtrained liquor an ounce of any ſpirituous water. It is to be continued in theſe doſes till it either acts upon the kidneys, the ſtomach, the pulſe, or the bowels.

2. Stem even, ſhorter by half than the foregoing. Peduncles villoſe. Leaves ſeſſile, lanceolate, not wrinkled but even, and almoſt entire. The flowers are very like thoſe of *D. purpurea* in form, ſize and colour, but the dots of the palate are more copious and without the pale iris: the upper lip is more deeply two-lobed, the lower very obtuſe, and the lateral ſegments reflex: the anthers have ferruginous dots. It is a native of Spain, and is perennial[d].

3. This has the appearance of the firſt ſort. The leaves are tomentoſe, veined, ſerrate; the lower lanceolate-ovate, the upper broad-lanceolate, all decurrent and having the decurrent ſides reflex. The bunch or ſpike of flowers the ſame as in *D. purpurea*. The corolla purple with a pale throat over which are ſprinkled blood-red dots; border four-cleft, the upper lobe undivided, the lower longer and ciliate. It ſeems to be a daughter of the firſt ſpecies by Verbaſcum Thapſus[e].]

It ſeldom riſes much more than a foot and half high; the lower leaves are ten inches long, and three broad in the middle. The flowers are ſmaller than

[a] Curtis. [b] Woodv. Mſ. [c] Gartner. [d] Linn. mant. [e] Linn. ſpec.

thoſe of the common ſort, and the ſegments are acute. It grows naturally in Spain, whence Mr. Miller received the ſeeds. [It was cultivated by him in 1759 : flowers from june to auguſt, and is perennial[f].]

4. This has very long obtuſe leaves near the root : the ſtalk is ſmall, and riſes from two to three feet high : the lower part of it has ſmooth leaves growing cloſe together, about three inches long and one inch broad, ending in obtuſe points : the upper part of the ſtalk for ten inches in length, has ſmall yellow flowers, cloſely ranged on one ſide of it, having a few very ſmall acute leaves placed between them, ſituated on the oppoſite ſide of the ſtalk.

[Diſtinct from the next ſpecies, in having the leaves ſmooth, harder and narrower ; the flowers ſmaller, thicker in the ſpike, pale not ſpotted, the ſegments of the calyx and corolla acute, triangular, thoſe of the latter five almoſt equal, the upper one manifeſtly biſid[g].

The ſpike nods at top from the beginning[h]. Leaves lanceolate, half a foot in length, nerved, ſeſſile ; the nerves villoſe underneath. The upper calycine leaf ſhorter. Calyx, ſtyle, germ pubeſcent with capitate hairs[i]. Perennial.

Native of France ; Switzerland in the government of Aigle, about Geneva ; Sileſia ; Carniola ; Piedmont ; about Salerno and Naples.—Cultivated in 1629[k]. It flowers in july and auguſt.]

5. This has long ſmooth-veined leaves at bottom ; the ſtalk is ſtrong, two feet and a half high. Leaves five inches long, one inch and a half broad, ending in acute points, having many longitudinal veins, and being ſlightly ferrate ; the upper part of the ſtalk is adorned with large yellow flowers, nearly of the ſame ſize with thoſe of the firſt ſort ; the brim having acute points, and the upper lip being entire.

[It differs from the foregoing in having the flowers much larger ; though ſcarcely different in ſpecies, yet all writers chooſe to diſtinguiſh it principally on this account[l].

It is diſtinguiſhed from the foregoing by the leaflets of the calyx being more acuminate ; the corollas larger, ſwelling at bottom, ochroleucous, dotted on the inſide with brown[m].

It is more tender than the firſt ſpecies, and ſomewhat viſcid. The ſtem is two feet high and ſubpubeſcent. The leaves ſmooth on their upper ſurface, ſubpubeſcent on their lower, without any of the anaſtomoſing veins, the edge very ſlightly and ſharply ferrate. The raceme nodding at top ; bractes narrower and more obtuſe ; corolla a little ſmaller, very ſoftly pubeſcent, pale yellow, hairy within, and ſpotted with brown, the upper lip very ſhort, very obtuſe, cloven, the lateral and lower diviſions acute ; ſtyle ſtraight ; ſtigma biſid, convergent. Capſules all on one ſide, remote, ovate-oblong, acuminate, twice the length of the calyx[n].

Native of Germany, Switzerland, Geneva, Auſtria, Piedmont ; flowering with the former.—Cultivated in 1596, by Gerarde[o].

6. *Stem* ſtrict, even, ſix feet high. Leaves ſeſſile, lanceolate, even, marked with lines, quite entire. *Flowers* in an upright raceme from each of the upper axils : bractes linear-lanceolate, reflex : pedicels very ſhort, ſolitary : the three upper leaves of the calyx approximating : corolla a little longer than the calyx, pubeſcent, yellowiſh within, the two upper diviſions obſcure, the ſide ones ſharp, the loweſt longer : ſtamens flexuoſe, without any rudiment of a fifth : ſtyle the length of the flower. Perennial[p].

Leaves beneath hairy and hirſute, whitiſh, the rib ſharp and nerved, above ſmooth and dark green, on the edge having a few ſmall teeth. The whole corolla ſubhirſute. Style the length of the ſtamens, but as the flower decays extended beyond the calyx. Height of the plant three feet[q].]

Stem near ſix feet high, putting out ſome ſlender branches towards the bottom, where it has narrow ſmall leaves, three inches long and one third of an inch broad. The flowers terminate the ſtem in a very long ſpike or raceme, having a few very ſmall leaves between them : the corolla has the colour of ruſty iron, and expands in june, [or july.

Native of Italy and about Conſtantinople. Cultivated in 1597[r].

7. *Stem* underſhrubby, with a few oppoſite branches. *Leaves*, when it does not flower, crowded, but on the flowering ſtem alternate. *Flowers* on terminating racemes : bractes lanceolate : calycine leaflets ovate, acutiſh, patulous : corollas drooping, obtuſe, yellowiſh within, reticulated and ruſous at bottom ; pale ruſous on the outſide, eſpecially at the back ; upper lip half cloven and recurved, lower three-parted the middle part a little longer than the others.

Native of Spain[s]. Introduced about 1778. It flowers in july and auguſt[t].]

8. This plant has a ſhrubby ſtalk, four and ſometimes five or ſix feet high, dividing into ſeveral branches. Leaves lanceolate, rough, near five inches long, and two broad in the middle, gradually decreaſing to both ends, having a few ſhort ſerratures on their edges, placed alternately on the branches, each of which is terminated by a looſe ſpike of flowers, near a foot in length : they are of an orange-colour intermixed with yellow, and are ſhaped ſomewhat like the flowers of Acanthus.

It grows naturally in the Canary iſlands, whence the ſeeds were firſt brought to England, and many of the plants were raiſed, in the Biſhop of London's garden at Fulham, part of which were ſent to the royal gardens at Hampton Court, and into Holland.

[It was alſo cultivated in 1698, by the Dutcheſs of Beaufort[u].

9. This is a very handſome plant. The branches are rough with hairs. Leaves approximating, near a foot in length, ſeſſile, gradually dilated from the baſe into an oblong form, ſerrate in the middle, acuminate, ſmooth on the upper ſurface, rough with hairs and whitiſh on the lower. Pedunele terminating the branch, ſolitary, round, upright, a hand or more in length, porous on the inſide, ending in an ovate ſpike with the flowers hanging down. Bractes before the flowers open form a coma. Calycine leaflets hirſute. The corolla is nearly of the ſame ſize as in *D. ferruginea*, gibbous below, the border four-cleft, the lip obtuſe.

Native of Madeira, in woods, where it was found by Maſſon[x].—Introduced in 1777. It flowers in july and auguſt[y].]

10. Root-leaves many, ſmooth ; among theſe ariſes the ſtalk about a foot high ; the leaves on it are ſmooth, from four to five inches long, and one inch and a half broad in the middle, half-ſtem-claſping. Spike of flowers terminating, ſhort, looſe. Corollas yellow, almoſt as large as thoſe of n. 5., but ſhorter. It flowers in may, and the ſeeds ripen in autumn.

It grows naturally in Tartary, whence the ſeeds were ſent to the imperial garden at Peterſburgh, and thence to Mr. Miller, who cultivated them in 1759.

[11. Stem herbaceous, a foot and half high, almoſt upright. Leaves quite entire, oppoſite. Flowers ſeſſile : calyx five-cleft : corolla pale violet, bell-ſhaped, ventricoſe at bottom, five-cleft, the ſegments obtuſe, the uppermoſt emarginate. Capſule ovate, acute, two-celled.

Native of Cochinchina.

12. Stem ceſpitoſe, erect, a foot high, round, ſmooth. Leaves acute, ferrate, oppoſite, on ſhort petioles. Segments of the calyx five, erect, the uppermoſt larger, ſometimes biſid. Corolla duſky purple, bell-ſhaped, ventricoſe, four-cleft, the upper ſegment larger than the reſt. Stigma ſcrew-ſhaped. Capſule ovate-conic, two-grooved, two-celled.

Native of China[z].]

PROPAGATION AND CULTURE.

If the ſeeds of the firſt ſort are permitted to ſcatter, the plants will come up in the ſpring, and require only to be weeded out where they are too numerous. The ſeeds of this and of the other ſorts ſhould be ſown in autumn, for thoſe which are ſown in the ſpring ſeldom ſucceed, or at leaſt lie a year in the ground before they grow.

8. This plant begins to flower in may, and there is generally a ſucceſſion of flowers on the ſame plant, till the winter puts a ſtop to them, which renders the plant more valuable. It is propagated by ſeeds, which ſhould be ſown in pots filled with light earth, in the autumn, ſoon after the ſeeds are ripe; theſe pots ſhould be plunged into an old bed of tanners bark, whoſe heat is gone, and in mild weather the glaſſes ſhould be drawn off to admit the air; but in hard rains and froſt they muſt be kept on, to protect the ſeeds from both, which frequently deſtroy them here when they are expoſed: in the ſpring the plants will come up, when they ſhould enjoy the free air in mild weather, but muſt be protected from the cold. When theſe are large enough to tranſplant, they ſhould be each planted into a ſeparate ſmall pot filled with light earth, and placed under the frame till they have taken new root, then they ſhould be gradually inured to the open air. During the ſummer ſeaſon the plants ſhould remain abroad in a ſheltered ſituation, but in the winter they muſt be placed in a green-houſe, for they will not live abroad in England; they muſt not be kept too warm and cloſe in the houſe, for they only want protection from the froſt; therefore in mild weather, they ſhould have free air conſtantly admitted to them, and they require frequent waterings, but they ſhould not have it in too great plenty in winter.

9. The ninth muſt have the ſame treatment.

[a] Linn. [b] Linn. ſuppl.

DESCRIPTIONS, &c.

These are beautiful trees, natives of the East Indies: the leaves are large and of a leathery substance: the flowers are axillary or terminating, sometimes very large; the fruit approaches to that of Clusia. Jussieu doubts whether this genus may not be allied more nearly to the natural order of Guttiferæ than of Magnoliæ, in which he has placed it, although the leaves be alternate[a].

1. Branches alternate, wrinkled, dusky, smooth. Leaves serrulate from the middle to the end; the serrulations however are scarcely visible; they are smooth on both sides, paler underneath, nerves alternate, parallel, curved up, with a very fine net of veins between, spreading, about a span in length, and a hand in breadth. Petioles semicylindric, channelled, villose, an inch long. Flowers terminating on the extreme branchlets, subsolitary, pedunculed.

Native of the island of Ceylon, named there *Gudapara* and *Rumunidale*.—A decoction of the leaves is used by the inhabitants for cleansing foul ulcers[b].

2. This is a lofty tree, with thick wrinkled ash-coloured smooth branches. Leaves obtuse with a point, waved and toothletted, with parallel nerves almost opposite, the upper surface smooth, the lower obscure, brownish, about a foot in length, and a hand in breadth. Petioles thick, scarcely an inch in length. Flowers on the branchlets terminating.

Found, according to Rheede, in Malabar, by Thunberg in Java[c].

3. Leaves petioled, acuminate, with opposite parallel nerves. Flowers terminating.

Native of Amboina, Celebes and Macassar, according to Rumphius[d].

4. Branches alternate, wrinkled, dusky, smooth. Leaves approximating, drawn to a point at bottom, entire, remotely serrate at top with obsolete serratures, truncate and subretuse at the end, smooth on both sides, nerves parallel, alternate, curved up, with a fine net of veins between them, spreading, almost a hand wide and twice that length. Petioles semicylindric, channelled, hirsute at the base, scarcely an inch long. Flowers terminating.

Native of Ceylon, in woods[e].

5. Leaves petioled, finely serrate, nerves almost opposite or alternate, parallel. Flowers on lateral peduncles, by threes, pedicelled.

Native of Celebes, Macassar and Java, according to Rumphius[f].

6. Branches alternate, wrinkled, ash-coloured, smooth. Leaves very obtuse or emarginate-retuse, entire at bottom, toothed towards the upper part and at the end, nerves almost opposite, parallel, directed upwards, smooth on both sides, darker-coloured underneath, a hand in length. Petioles angular, smooth, a little shorter than the leaf. Flowers on the branches, terminating, racemed, three or thereabouts together. Pedicels alternate, smooth, half an inch long[g]. According to Vahl, the peduncles are frequently from four to eight-flowered, branching at the base.

Native of Ceylon, where it is known by the name of *Diapara*[h].

7. This is a large tree, with numerous ascending branches. Leaves alternate, petioled, about the extremities of the branchlets, oblong, pointed, sharp-sawed, having large elevated parallel veins, smooth, shining, except when very young, then downy, from twelve to twenty inches long, and from four to six broad. Peduncles collected in bundles from tuberosities over the naked wood of the two or three year old branchlets, erect, round, smooth, two inches long, undivided, one-flowered. Flowers middle-sized, yellow. Petals oblong. Filamenta many; anthers sword-shaped. *Germs* five, short. Stigmas lanced, spreading. Pericarp pendulous, size of a small nutmeg. Seeds reniform.

[a] Juss. gen. [b] Thunb. in Linn. trans. [c] Ibid. [d] Ibid. [e] Ibid. [f] Ibid. [g] Ibid. [h] Ibid.

It is a native of the mountainous parts of Coromandel, where it flowers in march and april[i].

DIMORPHA. (*From δις twice, and μορφη form.*)
Lin. gen. Schreb. n. 1179. Parivoa. *Aubl.* 303. *Juss.* 350. Eperua. *Aubl.* 142. *Juss.* 349.
Class. 17. 4. Diadelphia Decandria.
Nat. order of *Papilionaceæ* or *Leguminosæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, rounded at the base, deeply three or four-cleft, obtuse.
COR. *Petal* very wide, ventricose, convolute at the sides, crenulate, inserted into the calyx below the stamens, placed at the lower side.
STAM. *Filaments* diadelphous, (single at the opening of the petal, and nine-cleft incumbent on the middle of the petal,) ascending, longer than the corolla. *Anthers* parallelopiped, incumbent.
PIST. *Germ* pedicelled, compressed, short. *Style* longer than the stamens. *Stigma* simple.
PER. *Legume* large, oblique, compressed, one-celled.
SEED single or few.

OBS. *Petal single, as in* Amorpha, *but occupying the place of the keel; the wings and standard are wanting.*
Parivoa, *Aubl. has an obovate one-seeded legume.*
Eperua, *Aubl. has the filaments thickened at the base and villose, (in the figure, five only have anthers;) legume sabre-shaped, with three or four seeds in it.*

ESSENTIAL CHARACTER.

Petal one large convolute, in place of the keel. Standard and wings none.

SPECIES.

1. Dimorpha falcata.
Eperua. *Aubl. pl. gui.* 1. *p.* 369. *t.* 142.
Leaves pinnate, pods falciform.
2. Dimorpha grandiflora.
Parivoa grandiflora. *Aubl. pl. gui.* 2. *p.* 757. *t.* 303.
Flowers larger than in the other species.
3. Dimorpha tomentosa.
Parivoa tomentosa. *Aubl. pl. gui.* 2. *p.* 759. *t.* 304.
Legume tomentose.

DESCRIPTIONS, &c.

1. A tall tree, upwards of sixty feet high, very much branched at top, and branches much scattered. Leaves alternate, pinnate, commonly three on a side; ovate-oblong, sharp-pointed. Flowers numerous, spiked. Spikes alternate, extremely long, pendulous, axillary, and terminal.

Native of woods in Guiana; flowering in september.

2. A large tree, with a trunk more than two feet in diameter. Leaves winged and alternate, leaflets opposite, each pair at a distance from the other, entire, ovate-lanceolate, sharp-pointed. Flowers purplish, large, borne in clusters. The wood of this tree is reddish, solid and compact, and is used for various important purposes.

It is found in Guiana, and flowers in september.

3. A tree upwards of twenty feet high, very much branched at top; and branches much scattered. Leaves alternate, pinnated, with two or three alternate leaflets. Flowers scattered, terminal, axillary.

Flowers in september, and grows near the banks of rivers in Guiana[k].

DIMORPHOTHECA. See *Calendula*.

DIODIA. (*Διοδια, subvectio; from its growing by way sides.*)
Lin. gen. n. 122. *Reich.* 129. *Schreb.* 158. *Gronov. Gærtn. t.* 25. *Juss.* 197.
Class. 4. 1. Tetrandria Monogynia.
Nat. order of *Stellatæ*.—*Rubiaceæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* two-leaved: (two or four-leaved, *G.*) *leaflets* subovate, superior equal, permanent: (two larger, the length of half the fruit. *G.*)
COR. one-petalled, funnel-form. *Tube* slender, long. *Border* small, spreading, four-partod: *divisions* lanceolate.

[i] Roxb. corom. [k] Aublet.

STAM. *Filaments* four, briſtle-ſhaped, upright. *Anthers* verſatile.
PIST. *Germ* roundiſh, four-ſided, inferior. *Style* filiform, length of the ſtamens. *Stigma* two-cleft.
PER. *Capſule* ovate, four-cornered, crowned, larger than the calyx, two-celled, two-valved: (valvelets, bipartile, eight-furrowed, *G.*)
SEED ſolitary, ovate-oblong, even, convex on one ſide, flat on the other; ſhining: (with two furrows and a ridge between them, *G.*)

ESSENTIAL CHARACTER.

Cor. one-petalled, funnel-form. *Capſ.* two-celled, two-ſeeded.

SPECIES.

1. Diodia virginica.
Lin. ſpec. 151. *ſyſt.* 149. *Reich.* 298. *hort. cliff.* 493. *Gron. virg.* 71. *Gærtn. fruct.* 121. *Swartz prodr.* 151.

2. Diodia ſimplex.
Swartz prodr. 29.
Stem herbaceous ſimple almoſt erect ſmooth and even, leaves ovate-lanceolate.
3. Diodia proſtrata.
Swartz prodr. 30.
Diodioides. *Loeſ. itin.* 201.
Stem ſuffruticoſe ſubdivided, branches proſtrate filiform, leaves linear ſomewhat birſute revolute.
4. Diodia ſcandens.
Swartz prodr. 30.
Stem ſcandent ſuffruticoſe, leaves ovate-lanceolate rigid rugged.
5. Diodia ſarmentoſa.
Swartz prodr. 30.
Stem flaccid ſtrubby, branches oppoſite ſpreading, leaves oblong acute ſomewhat ragged.
6. Diodia verticillata.
Vahl ſymb. 2. 28.
Smooth, leaves lanceolate in whorls rugged at the edge, ſtem herbaceous erect.

DESCRIPTIONS, *&c.*

1. Stems procumbent, red; branches alternate. Leaves oppoſite. Flowers white [a]. The calyx in ſome is two-leaved only, in others unequally four-leaved, that is with two very minute leaves placed in the interſtices of the larger, and this even ſeems to be the more natural number. Capſule ſmall, of a pale bay colour, the ſurface often chagreened with very minute linear acuminate chaffy white ſquamules, eſpecially towards the end; but which, when the fruit is ripe, are eaſily wiped off, ſo that it is uſually ſmooth. Receptacle none; the ſeeds being fixed to the middle of the partition; theſe are blackiſh [b].—Native of Virginia.

2, 3, 4, 5. Natives of the Weſt Indies. The ſecond, third and fifth of Jamaica, and the fourth of Hiſpaniola [c].

6. Stem ſimple, a foot high, ſmooth, as is alſo the whole plant, even. Leaves ſeſſile, from five to eight in each whorl, unequal, without any viſible veins or nerves, not marked with lines, very rugged about the edge, connected by a ſtipulaceous ciliate membrane. Flowers ſeveral together in whorls, incloſed by the ſtipule; the terminating whorl larger than the others. Capſule two-celled, linear, ſomewhat compreſſed, ciliate on both ſides at top, crowned with two teeth. Seed ſingle in each cell, linear.
Native of the iſland of Santa Cruz; ſent by Pflug [d].

DIONÆA. (*One of the names of Venus; from her mother Dione. A genus conſtituted by Ellis.*)
Lin. gen. Reich. n. 584. *Schreb.* 729. *Ellis monogr. Jaſſ.* 431.
Claſs. 10. 1. Decandria Monogynia.
Nat. order of *Gruinales*.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved, upright; *leaflets* oblong, acute, permanent.
COR. *Petals* five, ſeſſile, oblong, obtuſe, concave.
STAM. *Filaments* ten, ſubulate, ſhorter. *Anthers* roundiſh, pollen tricoccous.
PIST. *Germ* roundiſh, depreſſed, crenate. *Style* filiform, ſhorter than the filaments. *Stigma* ſpreading, fringed on the edge.
PER. *Capſule* one-celled, gibbous.
SEEDS very many, ſubovate, very ſmall, affixed to the baſe of the capſule.
OBS. *The number of ſtamens is not always conſtant.*

ESSENTIAL CHARACTER.

Cal. five-leaved. *Pet.* five. *Capſ.* one-celled, gibbous, containing many ſeeds.

SPECIES.

1. Dionæa Muſcipula. *Venus's fly-trap.*
Lin. ſyſt. 403. *Reich.* 281. *mant.* 238. *act. upſ. nov.* 1. 98. *t.* 8. *Ellis monogr. fig. & deſcr. Shaw nat. miſcel.* t. 40.

DESCRIPTION, *&c.*

Root ſquamous, ſending forth but few fibres, like thoſe of ſome bulbs, and perennial. *Stalk* about ſix inches high, round, ſmooth, without leaves, ending in a ſpike of flowers. *Leaves* many, inclining to bend downwards, and placed in a circular order, jointed, ſucculent; the lower joint, which is a kind of ſtalk, is flat, longiſh, two-edged, and inclining to heart-ſhaped. In ſome varieties they are ſerrate on the edges near the top: the upper joint conſiſts of two lobes, each ſemi-oval, the margins furniſhed with ſtiff hairs like the eye-laſhes, embracing or locking into each other when they cloſe: this they do when they are irritated within: the upper ſurface of theſe lobes is covered with ſmall red glands, appearing, when highly magnified, like the fruit of the Arbutus compreſſed: among the glands, about the middle of each lobe, are three very ſmall erect ſpines; when the lobes incloſe any ſubſtance, they never open again while it continues there; if it can be ſhoved out ſo as not to ſtrain the lobes, they expand again, but if force be uſed to open them, ſo ſtrong has nature formed the ſpring of their fibres, that one of the lobes generally ſnaps off rather than yield. *Flowers* milk-white, on peduncles, with a little pointed bracte at the bottom of each [e].

What Ellis calls the lower joint of the leaf, Linneus looks upon as the petiole winged in the ſame manner as in the Orange. The ſtem is a ſcape. The flowers grow in a corymb reſembling an umbel: the petals are marked with ſeven ſtreaks and bend in at the end. Linneus affirms that when the entrapped inſect ceaſes to ſtruggle, and is quiet, the leaf opens and permits it to eſcape. This does not agree with Ellis's account: for he affirms that the lobes never open again, ſo long as the animal continues there. He thinks it probable that a ſweet liquor diſcharged by the red glands tempts the inſect to its deſtruction. He adds, that if a ſtraw or a pin be introduced between the lobes, they will graſp it as faſt as if it were an inſect.

A ſpecimen of this ſingular plant was firſt ſent to Mr. Ellis in the year 1765, by Mr. Peter Collinſon; and he received it from Mr. John Bartram of Philadelphia, botaniſt to the King. But we are indebted to Mr. William Young, a native of Philadelphia, for the introduction of it alive, and in conſiderable quantities [f]. This, according to the Kew catalogue, was in 1768.

It is a native of the ſwamps of North Carolina, near the confines of South Carolina, about the latitude of 33°. N., where the winters are ſhort, and the ſummers very hot; it flowers there in july and auguſt.

The plants introduced by Mr. Young were all loſt: and this ſingular plant was again brought into our gardens in 1789; but it will be difficult long to preſerve a ſwamp plant from Carolina.

PROPAGATION AND CULTURE.

Being a ſwamp plant, a north-eaſt aſpect will be the propereſt to plant it in, to keep it from the direct rays of the meridian ſun; and in winter, it will be neceſſary to ſhelter it with a bell-glaſs; which

[a] Linn. ſyſt. [b] Gærtner. [c] Swartz. [d] Vahl.
[e] Ellis [f] Ibid.

ſhould

should be covered with straw or a mat in hard frosts. Its sensitive quality will be in proportion to the heat of the weather, as well as the vigour of the plant.

It may also be planted in pots of light moorish earth, for in such the plants come over mixed with white sand, and placed in pans of water, in an airy stove; where the heat of such a situation, being like that of its native country, will make it surprizingly active.

Our summers are not warm enough to ripen the seed [a].]

DIOSCOREA. *(So named in honour of Pedacius Dioscorides, of Anazarbæa, who is supposed to have lived in the time of Nero. He is author of a large treatise on the Materia Medica in Greek.)*

   Leaves cordate five-lobed nine-nerved.

12. Dioscorea japonica.
   Lin. syst. 889. *Thunb. jap.* 151.
   Leaves cordate acuminate nine-nerved.]

13. Dioscorea hastata.
   Mill. dict. n. 2.
   D. scandens, fol. hast. fructu racemoso. *Houst. Mss.*
   Leaves hastate, stem even, racemes very long.

[14. Dioscorea eburina.
   Lour. cochinch. 625. *Burm. ind.* 215? (Cylindrica), *Rheed. mal.* 7. 95. *t.* 50. (Kappa Kelengu).
   Leaves heart-shaped seven-nerved alternate, flowers hermaphrodite in simple long racemes.

15. Dioscorea cirrhosa.
   Lour. cochinch. 625.
   Leaves ovate-lanceolate three-nerved, flowers hermaphrodite three-stamened, stem cirrhose.

DESCRIPTIONS, &c.

Roots usually tuberous. Stem twining from right to left. Flowers axillary, in spikes or racemes. Perennial.

1. Root very large and thick. Stalks spiny, slender. Leaves quinate, flat, smooth, thin, on petioles striated within: the midrib puts out several transverse nerves, and these others covering the back as it were with a net. Flowers first yellow, then turning blackish [a].

Native of the East Indies and the Society Isles.

2. This is very nearly allied to the foregoing, and it may be doubted whether it be a distinct species [b].

The stalks are round, slender, smooth, spiny. Leaves above dusky green, beneath smooth and shining, with whitish prominent nerves, on long petioles [c].

Capsule two inches long, from an emarginate and a kind of cordate base prolonged into an elliptic form, and contracted at top into a short dagger point; otherwise it resembles that of *D. sativa*, except that it is much stiffer. Seeds in pairs, semi-elliptic, about an inch long, of a cinnamon colour [d].

Native of Malabar.

3. Stem winged bearing tubers. Leaves nerved, semitrifid or palmate, the side lobes next the petiole much emarginated and produced behind into sinuous lobes.

Native of Surinam [e].

4. Stem suffruticose, twining, round, slender, very much branched: with many straight, short, scattered prickles. Leaves ovate, five-nerved, smooth, alternate, on long slender petioles. Flowers in long, spiked, lateral racemes. The calyx has from three to six acute, very short, unequal, spreading leaflets. The corolla has six ovate, concave petals, almost closed, and of a dusky purple colour. Filaments awl-shaped, equal to the corolla, with roundish

Stem ſtaccid ſhrubby, branches oppoſite ſpreading, leaves oblong acute ſomewhat rugged.
6. Diodia verticillata.
Vahl ſymb. 2. 28.
Smooth, leaves lanceolate in whorls rugged at the edge, ſtem herbaceous erect.

DESCRIPTIONS, *&c.*

1. Stems procumbent, red; branches alternate. Leaves oppoſite. Flowers white[a]. The calyx in ſome is two-leaved only, in others unequally four-leaved, that is with two very minute leaves placed in the interſtices of the larger, and this even ſeems to be the more natural number. Capſule ſmall, of a pale bay colour, the ſurface often chagreened with very minute linear acuminate chaffy white ſquamules, eſpecially towards the end; but which, when the fruit is ripe, are eaſily wiped off, ſo that it is uſually ſmooth. Receptacle none; the ſeeds being fixed to the middle of the partition; theſe are blackiſh[b].—Native of Virginia.

2. 3. 4. 5. Natives of the Weſt Indies. The ſecond, third and fifth of Jamaica, and the fourth of Hiſpaniola[c].

6. Stem ſimple, a foot high, ſmooth, as is alſo the whole plant, even. Leaves ſeſſile, from five to eight in each whorl, unequal, without any viſible veins or nerves, not marked with lines, very rugged about the edge, connected by a ſtipulaceous ciliate membrane. Flowers ſeveral together in whorls, incloſed by the ſtipule; the terminating whorl larger than the others. Capſule two-celled, linear, ſomewhat compreſſed, ciliate on both ſides at top, crowned with two teeth. Seed ſingle in each cell, linear.
Native of the iſland of Santa Cruz; ſent by Pflug[d].

DESCRIPTION, *&c.*

Root ſquamous, ſending forth but few fibres, like thoſe of ſome bulbs, and perennial. *Stalk* about ſix inches high, round, ſmooth, without leaves, ending in a ſpike of flowers. *Leaves* many, inclining to bend downwards, and placed in a circular order, jointed, ſucculent; the lower joint, which is a kind of ſtalk, is flat, longiſh, two-edged, and inclining to heart-ſhaped. In ſome varieties they are ſerrate on the edges near the top: the upper joint conſiſts of two lobes, each ſemi-oval, the margins furniſhed with ſtiff hairs like the eye-laſhes, embracing or locking into each other when they cloſe: this they do when they are irritated within; the upper ſurface of theſe lobes is covered with ſmall red glands, appearing, when highly magnified, like the fruit of the Arbutus compreſſed: among the glands, about the middle of each lobe, are three very ſmall erect ſpines; when the lobes incloſe any ſubſtance, they never open again while it continues there; if it can be ſhoved out ſo as not to ſtrain the lobes, they expand again, but if force be uſed to open them, ſo ſtrong has nature formed the ſpring of their fibres, that one of the lobes generally ſnaps off rather than yield. *Flowers* milk-white, on pedunckes, with a little pointed bracte at the bottom of each[a].

What Ellis calls the lower joint of the leaf, Linnæus looks upon as the petiole winged in the ſame manner as in the Orange. The ſtem is a ſcape. The flowers grow in a corymb reſembling an umbel: the petals are marked with ſeven ſtreaks and bend in at the end. Linnæus affirms that when the entrapped inſect ceaſes to ſtruggle, and is quiet, the leaf opens and permits it to eſcape. This does not agree with Ellis's account: for he affirms that the lobes never open again, ſo long as the animal continues there. He thinks it probable that a ſweet liquor diſcharged by the red glands tempts the inſect to its deſtruction. He adds, that if a ſtraw or a pin be introduced between the lobes, they will graſp it as faſt as if it were an inſect.

A ſpecimen of this ſingular plant was firſt ſent to Mr. Ellis in the year 1765, by Mr. Peter Collinſon; and he received it from Mr. John Bartram of Philadelphia, botaniſt to the King. But we are indebted to Mr. William Young, a native of Philadelphia, for the introduction of it alive, and in conſiderable quantities[b]. This, according to the Kew catalogue, was in 1768.

It is a native of the ſwamps of North Carolina, near the confines of South Carolina, about the latitude of 33°. N., where the winters are ſhort, and the ſummers very hot; it flowers there in July and auguſt.

The plants introduced by Mr. Young were all loſt: and this ſingular plant was again brought into our gardens in 1789; but it will be difficult long to preſerve a ſwamp plant from Carolina.

PROPAGATION AND CULTURE.

Being a ſwamp plant, a north-eaſt aſpect will be the propereſt to plant it in, to keep it from the direct rays of the meridian ſun; and in winter, it will be neceſſary to ſhelter it with a bell-glaſs; which

[a] Ellis. [b] Ibid.

ſhould be covered with ſtraw or a mat in hard froſts. Its ſenſitive quality will be in proportion to the heat of the weather, as well as the vigour of the plant.

It may alſo be planted in pots of light moiſtiſh earth, for in ſuch the plants come over mixed with white ſand, and placed in pans of water, in an airy ſtove; where the heat of ſuch a ſituation, being like that of its native country, will make it ſurprizingly active.

Our ſummers are not warm enough to ripen the ſeed [a].

DIOSCOREA. *(So named in honour of Pedacius Dioſcorides, of Anazarbæa, who is ſuppoſed to have lived in the time of Nero. He is author of a large treatiſe on the Materia Medica in Greek.)*

Leaves haſtate, ſtem even, racemes very long.

[14. Dioſcorea eburina.
Lour. cochinch. 625. *Burm. ind.* 215? (Cylindrica). *Rheed. mal.* 7. 95. *t.* 50. (Kappa Kelengu).
Leaves heart-ſhaped ſeven-nerved alternate, flowers hermaphrodite in ſimple long racemes.

15. Dioſcorea cirrhoſa.
Lour. cochinch. 625.
Leaves ovate-lanceolate three-nerved, flowers hermaphrodite three-ſtamened, ſtem cirrhoſe.

DESCRIPTIONS, *&c.*

Roots uſually tuberous. Stem twining from right to left. Flowers axillary, in ſpikes or racemes. Perennial.

1. Root very large and thick. Stalks ſpiny, ſlender. Leaves quinate, flat, ſmooth, thin, on petioles ſtriated within: the midrib puts out ſeveral tranſverſe nerves, and theſe others covering the back as it were with a net. Flowers firſt yellow, then turning blackiſh [a].

Native of the Eaſt Indies and the Society Iſles.

2. This is very nearly allied to the foregoing, and it may be doubted whether it be a diſtinct ſpecies [b].

The ſtalks are round, ſlender, ſmooth, ſpiny. Leaves above duſky green, beneath ſmooth and ſhining, with whitiſh prominent nerves, on long petioles [c].

Capſule two inches long, from an emarginate and a kind of cordate baſe prolonged into an elliptic form, and contracted at top into a ſhort dagger point; otherwiſe it reſembles that of *D. ſativa*, except that it is much ſtiffer. Seeds in pairs, ſemi-elliptic, about an inch long, of a cinnamon colour [d].

Native of Malabar.

3. Stem winged bearing tubers. Leaves nerved, ſemitrifid or palmate, the ſide lobes next the petiole much emarginated and produced behind into ſinuous lobes.

Native of Surinam [e].

4. Stem ſuffruticoſe, twining, round, ſlender, very much branched: with many ſtraight, ſhort, ſcattered prickles. Leaves ovate, five-nerved, ſmooth, alternate, on long ſlender petioles. Flowers in long, ſpiked, lateral racemes. The calyx has from three to ſix acute, very ſhort, unequal, ſpreading leaflets. The corolla has ſix ovate, concave petals, almoſt cloſed, and of a duſky purple colour. Filaments awl-ſhaped, equal to the corolla, with roundiſh

[a] Hort. malab. [b] Linn. ſpec. [c] Hort. malab. [d] Gærtner. [e] Linn. ſuppl.

anthers.

anthers. Germ inferior. The root is an oblong, efculent tuber, white within, pale yellow without, furrounded with fhort fibres[f].

Native of Malabar and Cochinchina.

5. Stem furnifhed with longitudinal membranes, like *Convolvulus Turbith*. Leaves very deeply cordate, fmooth, three-nerved, almoft twice as long as they are broad, acuminate[g].

Root a foot or more long, as big as a man's leg or thigh, brown on the outfide; within white or reddifh purple, vifcid, but when boiled very mealy. Stalk the bignefs of a goofe-quill, fquare, with a thin reddifh membrane at each corner, winding itfelf round poles nine or ten feet high, and putting out leaves at every three inches diftance, oppofite, on fquare winged footftalks two inches long. Leaves two inches and a half long, an inch and three quarters broad at the bafe, almoft heart-fhaped, pointed, yellowifh green, having many ribs arifing from the end of the footftalk with tranfverfe ones between. Peduncles axillary an inch or more in length, with fmall flowers of a yellowifh green colour[h].

Native both of the Eaft and Weft Indies, and cultivated there for food as well as the fixth and feventh fpecies.

5. This fpecies indeed has a better claim, as Forfter obferves, to the name of *fativa* than the feventh; for it is univerfally cultivated in the Eaft and Weft Indies, in Africa, and in all the iflands of the Southern ocean, within the torrid Zone, and even as far as New Zealand. The roots are frequently three feet long, and weigh thirty pounds. In all the iflands of the South Sea, this Yam is known by the Malay name *Uffi* or *Ubi*. The Portugueſe call this root *Inhame*, hence the French *Igname*, and our *Yam*.

Cultivated here in 1739, by Mr. Miller[i].

6. Stalks ſlender, ſomewhat woody, twining round each other. Leaves on long petioles, which are angular, grooved within, ſomewhat protuberant at the baſe; they are oblong, ſoft, ſmooth, thin, ſtretched out longer on one ſide than the other; the midrib ſends out four annular nerves, prominent on the lower ſurface[k].

The leaves have many nerves and are acuminate. From the axils grow tubers which take root[l].

Native of both Eaſt and Weſt Indies, and the iſlands of the South Seas.—Mr. Miller calls this the Yam, and quotes the ſynonym of Sloane, with winged ſtalks, whereas the ſtalks of this ſpecies are even.]

7. This has ſlender ſtalks, climbing to the height of eighteen or twenty feet. The leaves have five longitudinal veins, which ariſe from the footſtalks, and diverge towards the ſides, but meet again at the point; they ſtand upon pretty long footſtalks, and from the baſe of theſe ariſe the branching ſpikes of flowers, which are ſmall and have no beauty.

[Leaves ſmooth, acute, nerved, ſoft, equal in length and breadth[m].

Root a foot broad and flatter than in n. 5. almoſt palmated like ſome Orchiſes, dirty brown on the outſide. Stalks not winged but round[n].—If it be Sloane's plant, it is the Negro Country Yam, which he ſays is much planted in Jamaica.

Browne calls it the Wild Yam (if it be his third ſpecies and not rather his firſt), and ſays that it is not put to any uſe in Jamaica. He refers to Fagopyrum ſcandens, *&c.* of Sloane 138.—There is much confuſion in the ſynonyms.

Capſule obovate-rounded, leathery, three-ſided, compreſſed into three wings, valves opening along the edge of the wings, accompanied in the middle with a very narrow partition, to the inner edge of which the ſeeds are fixed; theſe are irregularly triangular or roundiſh, and of a browniſh red colour[o].

Native of the Eaſt and Weſt Indies, and Japan. Mr. Miller received the ſeeds from Jamaica by Dr. Houſtoun, before the year 1733.

[f] Loureiro. [g] Linn. ſyſt. [h] Sloane. [i] Hort. kew. [k] Hort. malab. [l] Linn. ſyſt. [m] Ibid. [n] Sloane. [o] Gaertner.

The Yam is largely cultivated for food in Africa and the Eaſt and Weſt Indies, eſpecially in the latter for the negroes. The roots grow to a great ſize, are mealy, and eſteemed to be eaſy of digeſtion; they are palatable, and not inferior to any roots now in uſe, either for delicacy of flavour or nutriment. They are eaten inſtead of bread, either roaſted on the embers or boiled; the flower is alſo made into bread and puddings.

In Otaheite they make a diſh which they eſteem very delicious, from the roots of the Yam, with the kernel of the Coco nut ſcraped, and the pulp of the Muſa or Banana. The juice of Yam roots freſh is acrid, and excites an itching on the ſkin. There are many varieties of theſe roots, ſome ſpreading out like the fingers (Rumph. t. 121.), others twiſted like a ſerpent (Rumph. t. 122.), others again very ſmall, ſcarcely weighing more than a pound, with a whitiſh aſh-coloured bark, whereas the bark is commonly black. The fleſh of the Yam is white or purpliſh, and viſcid, but becomes farinaceous or mealy when dreſſed. The varieties above-mentioned occurred to our circumnavigators in the iſland of Otaheite, and belong rather to the fifth ſpecies[p]: there are doubtleſs many varieties of a plant ſo generally cultivated.]

8. This has broad, round, heart-ſhaped leaves, which end in acute points; they have many longitudinal veins, which ariſe from the footſtalk, and diverge to the ſide, but afterwards join at the point. The flowers come out on long looſe ſtrings, on ſhort pedicels.

[Native of Florida and Maryland. Cultivated 1759, by Mr. Miller[q].

9. This has the appearance of a *Smilax*. Stem round, woody, twining, unarmed. Leaves three-nerved, quite entire, ſmooth, petioled, pendulous. Racemes of male flowers axillary, oppoſite, ſolitary, ſubvilloſe, compoſed of three cylindric aments; the flowers are almoſt ſeſſile[r].—Mr. Miller ſeems to confound this with the foregoing.

Native of the Eaſt Indies, Japan, and Cochinchina, where the roots are preferred to all others. Loureiro doubts whether this be different from the twelfth.

10. The whole plant ſmooth. Stem round, climbing. Leaves alternate, entire, even, a hand long and broad, the upper ones gradually ſmaller; petioles a finger's length. Flowers axillary, in racemes, very ſmall. Capſule ovate-triangular with the corners winged, emarginate with the ſtyle permanent.

Native of Japan[s].

11. Stem filiform, twining, very long, with the reſt of the plant ſmooth. Leaves alternate, petioled, turned all the ſame way; the loweſt ſeven-lobed and very large; the higher ones five-lobed; the uppermoſt three-lobed and ſmaller; entire, acuminate, ſpreading. Petioles ſwelling at top and bottom, reflex, a finger's length. Racemes axillary two or three, looſe, near a ſpan in length. Flowers on patulous pedicels, a line in length, three or four together. Bracteas ovate, acute. Calyx ſaffron-coloured. Germ inferior, ſmooth. Capſule oblong-three-ſided, crowned with the permanent calyx, the corners ſharp, produced and compreſſed: it is often barren. Seeds minute, a pair in each wing.

Native of Japan[t].

12. The whole plant ſmooth. Stem filiform, angular, twining, branched. Branches ſcattered, few, reſembling the ſtem. Leaves oppoſite, petioled, oblong, entire, netted, an inch or an inch and half in length. Petiole ſomewhat angular, reflex-ſpreading, nearly the length of the leaf. Spikes axillary, one or two together, ſpreading, longer than the leaves, the rachis angular. It very much reſembles *Raſanca cordata*, were it not for the nine nerves on the leaves. The root of this is eaten boiled and cut into ſlices.—Native of Japan[u].]

[p] Forſter eſſent. p. 67. [q] Hort. kew. [r] Linn. ſyſt. [s] Thunberg. [t] Ibid. [u] Ibid.

13. This

13. This differs from the feventh in the ſhape of the leaves; theſe having two round ears at their baſe, but the middle extends to an acute point, like that of an halbert. The bunches of flowers are longer, and looſer than thoſe of the feventh ſort.

[14. Stem ſhrubby, unarmed, long, twining; the branches and petioles four-cornered. Leaves acuminate, ſmooth. Calyx three-leaved, with ovate, erect leaflets. Corolla three-petalled, ovate, fleſhy, yellow, concave, nearly equal to the calyx. Filaments hardly any: anthers roundiſh, two-celled, very ſmall. Germ inferior, oblong, three-ſided, without any ſtyle, but three oblong, reflex ſtigmas. Capſule oblong-oval, the angles entering deep. Seeds ovate, few. Root vertical, conſiſting of one or two tubers, three feet long, round, regular, ſharpiſh, curved a little, in ſhape and whiteneſs reſembling elephant's teeth, whence the vernacular name *Khoai nga*, and the trivial *eburina*.

15. Stem ſhrubby, long, ſlender, climbing. Leaves quite entire, ſmooth, oppoſite, petioled. Flowers very ſmall, axillary, on three-flowered peduncles. Calyx ſix-leaved, ſuperior: leaflets ovate, thick, curved, almoſt cloſed, permanent, in a double row, of which the inner is ſmaller. Corolla and filaments none. Anthers three oblong, erect. Germ oblong, three-cornered, without any ſtyle, but three acute, reflex ſtigmas. Capſule three-cornered-ovate. Seeds orbiculate, covered with a thin membranous aril. The root is a middle-ſized irregular tuber. The capſule is that of Dioſcorea, but it differs in ſeveral other characters.

Theſe are both natives of Cochinchina *.]

PROPAGATION AND CULTURE.

Theſe plants may be propagated by laying their branches into the ground, where in about three months they will put out roots, and may then be taken from the old plants, and put into ſeparate pots, which ſhould be plunged into the tan-bed in the ſtove. During winter they ſhould have little water; but in ſummer, when they are growing vigorouſly, they ſhould be watered three or four times a week; and in warm weather the glaſſes ſhould be opened to admit a large ſhare of free air. When ſeeds are received, they ſhould be immediately ſown in pots, and plunged into a hot-bed; where, if it be early in the ſpring, the plants will come up the ſame ſeaſon: but when they are ſown late, the ſeeds often remain in the ground till the following ſpring before they vegetate: in this caſe, the pots muſt be ſcreened from froſt during the winter, and put into a new hot-bed in the ſpring.

They may alſo be increaſed by cutting the roots in pieces, as practiſed for Potatoes; putting each piece in a pot filled with freſh earth, and plunged into the bark-pit; giving them little water until they ſhoot, leſt they ſhould rot. The roots do not grow to any great ſize here; and the plants having little beauty, ſeldom flowering, and requiring much care and room, they are ſeldom allowed a place in our ſtoves, except in very curious collections.

[Browne affirms that the roots of the Yams muſt be cut ſo as to have a little of the ſkin to each piece, for by that alone they germinate; the roots having no apparent buds or eyes, but caſting out their weakly ſtems from every part of the ſurface alike. Two or three plants are put into a hole: the holes are dug pretty regular, a foot and a half or two feet ſquare; theſe are afterwards filled from the adjoining banks, and the whole piece is covered with cane-traſh, which ſerves to keep the ground cool and freſh, and to prevent the growth of weeds, from which theſe plants muſt be carefully preſerved, until they grow ſufficiently to cover the mould. They are planted commonly in auguſt, and are ripe about november or december following.

When the roots are dug up, care ſhould be taken to wound them as little as poſſible, for ſuch as are cut throw out their ſprouts very early, and are ſeldom fit for any thing but planting. They ſhould be rubbed over with aſhes, and piled regularly on beds or hurdles, raiſed above the floor, that the air may come eaſily between them; or if they be piled in heaps, ſome aſhes ſhould be ſtrewed between the layers.]

* Loureiro.

DIOSMA. (Διος οσμη, *Jovis ſ. divinus odor*; *ſo called from its divine ſmell.*)

Lin. gen. n. 272. *Reich.* 292. *Schreb.* 374. *Juſſ.* 298. *Gærtn. t.* 94. *Hartogia Edit.* 6.

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Aggregatæ*.—*Rulaceæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved: *leaflets* ovate, acute, permanent.

COR. *Petals* five, ovate, obtuſe, ſeſſile, erect-ſpreading. *Nectaries* five, placed on the germ.

STAM. *Filaments* five, ſubulate. *Anthers* ſubovate, erect.

PIST. *Germ* crowned with the nectary. *Style* ſimple, length of the ſtamens. *Stigma* obſcure.

PER. *Capſules* five, ovate-acuminate, compreſſed, conjoined inwardly at the margin, diſtant at the tips, gaping at the upper future.

SEEDS ſolitary, oblong, ovate-depreſſed, acuminate at the point: an elaſtic *aril*, gaping on one ſide involving each ſeed.

OBS. *This is a multiform genus as to ſex, figure of nectaries, number of capſules; hence it was divided into* Hartogia *and* Dioſma; *but farther obſervations have brought them back into one genus.* Syſt. Veget. p. 199.

There are ſpecies with monoecous flowers, others with hermaphrodite; others with ten ſtamens, of which five are ſterile; and others differ otherwiſe from their congeners. R.

ESSENTIAL CHARACTER.

Cor. five-petalled. *Nect.* five on the germ. *Capſ.* three or five conjoined. *Seeds* veiled.

SPECIES.

1. Dioſma oppoſitifolia. *Oppoſite-leaved Dioſma.*

Leaves lanceolate ciliate wrinkled.
16. Diosma crenata. *Crenated Diosma.*
Lin. spec. 287. *syst.* 239. *Reich.* 558. *amœn* 4. 308.
Hartogia betulina. *Berg. cap.* 67.
Leaves lanceolate-oval opposite glandular-crenate, flowers solitary.
17. Diosma uniflora. *One-flowered Diosma.*
Lin. spec. 287. *syst.* 239. *Reich.* 558. *Pluk. mant. t.* 342. *f.* 5. (Cistus.) *Curt. magaz. t.* 273.
Hartogia uniflora. *Berg. cap.* 71.
Leaves ovate-oblong, flowers solitary terminating.
18. Diosma pulchella. *Oval-leaved Diosma.*
Lin. spec. 288. *syst.* 239. *Reich.* 559.
Hartogia pulchella. *Lin. syst.* 625. *edit.* 12. *Berg. cap.* 69.
Leaves ovate obtuse glandular-crenate, flowers twin axillary.
19. Diosma asiatica.
Lour. cochinch. 161.
Leaves lanceolate alternate, racemes subterminating.

DESCRIPTIONS, &c.

The species are all shrubs bearing the resemblance of heaths. The leaves are either opposite or scattered, frequently crowded and linear, sometimes having the edge underneath dotted. The flowers are in corymbs, or heads at the ends of the branches. The calyxes of some are glandulous, and dotted[a]. They are natives of the Cape of Good Hope.]

1. This rises to the height of three feet; the branches are very long and slender, and are produced from the stem very irregularly. The leaves are placed cross-wise in pairs, and are pointed; every evening they close up to the branches. The flowers are produced along the branches from between the leaves; and in the evening, when they are expanded, and the leaves closely embrace the branches, the whole plant appears as if covered with spikes of white flowers; and as it continues a long time in flower, it makes a fine appearance when intermixed with other exotics in the open air.

[Introduced 1774, by Mr. Francis Masson[b], into the Kew garden, but it had been cultivated before by Miller.]

2. This sort makes a very handsome shrub, growing to the height of five or six feet. Stalks woody, sending out many slender branches. The leaves come out alternately on every side. Flowers in small clusters at the ends of the shoots; they are white, and are succeeded by starry seed-vessels, having five corners, like those of the starry anise; each of these corners is a cell, (cocculus) containing one smooth, shining, oblong, black seed: these seed-vessels abound with a resin, which affords a grateful scent, as does also the whole plant.

[Cultivated by Mr. Miller in 1731[c].]

3. This is of humbler growth, seldom above three feet high, and spreads out into many branches. Leaves resembling those of heath. Flowers in clusters at the ends of the branches, like those of the second sort, but smaller, and the bunches not so large.

[According to Linneus, it has the habit and leaves of Juniper; these are smooth, and subtriquetrous.

The species which is figured in Mr. Miller's plates approaches, as he says, near to this, but the leaves are longer, more pointed and smooth. He describes it as growing three or four feet high, and sending out many lateral branches, which extend pretty wide every way, so as to form a large bushy head. The leaves are pretty long and narrow, ending in a sharp point; they are of a light green colour and smooth, and when bruised emit a strong balsamic odour. The flowers grow in small clusters towards the extremity of the branches, and are white. Probably therefore not this species.

4. This is a low bushy shrub, which seldom rises above two feet high, but spreads out its branches far on every side. The leaves are narrow and smooth, of a light green colour, and being ranged on each side the branches, appear flat on the upper and under side; when they are bruised, they emit a very strong penetrating odour. The flowers are produced singly from between the leaves; they are white and tinged on their upper surface. The nectary is less visible, and the seed-vessels are much smaller[d]. The Hottentots use this and other species to scent their ointments.

Cultivated in 1756, by Mr. Miller[e].

5. Leaves opposite. Flowers white, in a corymb. The barren stamens have almost the appearance of petals[f]. Introduced in 1786, by Mr. Fr. Masson[g].

6. Stem proliferous, two feet high, erect, brown, having the appearance of a large Heath or *Brunia nodiflora*. Leaves crowded, scattered, in eight rows, on the outside convex, roughish, edged and ciliate a little. Flowers purple, sessile and forming a head. Calyx imbricate, leaflets (the inmost and true ones only five) ovate, pubescent at the edge. Petals roundish, with the claws the length of the calyx. Nectaries very small, awnless[h].

7. Branches wand-like, even. Leaves alternate, subpetioled, linear-lanceolate, even above, longitudinally wrinkled underneath, smooth, quite entire at the edge, but as it were serrate with pellucid dots. Peduncles lateral, few-flowered, much shorter than the leaves. Flowers minute. Capsules usually solitary, bent in, and having a beak of the same length[i].

8. The branches are somewhat pubescent. The leaves petioled, crenulate about the edge with pellucid dots, even, not dotted on the disk, bluntish, scarcely acute[k].

9. Erect, with the branches scarcely pubescent. Leaves remote. Flowers from the upper axils of the leaves, solitary or in pairs, the peduncles longer than the leaf. Stamens five, real. Nectaries five, from alternate filaments, having at the tip a black larger antherine gland bifid at the base, with a small yellow head[l].

10. Branching. Leaves sessile, opposite, mucronate, even, dotted underneath. Corymbs terminating, subsessile. Calyx five-cornered. Petals bearded with white, small[m].

11. This species is singular, and distinguished from the rest by the leaves being so close together, that the whole stem is covered with them, by the branches being quadrangular and thicker towards the top, and by the large, solitary, terminating flower[n].

12. Branches filiform, erect, alternate, covered with alternate, minute leaves, like those of Heath,

[a] Jussieu. [b] Hort. kew. [c] Ibid. [d] Mill. fig. [e] Hort. kew. [f] Linn. [g] Hort. kew. [h] Linn. mant. [i] Linn. suppl. [k] Ibid. [l] Ibid. [m] Ibid. [n] Ibid.

subscrat-ous,

subscabrous, sessile, erect, terminating in a coloured callosity. Calyx membranaceous, lanceolate, erect. Petals often four, obovate, twice as long as the calyx, attenuated gradually into the claws. Stamens erect, the length of the calyx[a].

13. This resembles *D. ciliata* (n. 15.) but the petals are purple and roundish, with the claws three times the length of the calyx. Leaves subimbricate, keeled[b].

14. The leaves have a few hairs on both sides[c].

15. Leaves acute, ciliate about the edge and along the keel. Petals oblong, with the claws scarcely longer than the calyx[d].

16. Leaves of the calyx subulate and crenate[e].

17. Leaflets of the calyx ovate, large and almost broader than the leaves[f].

18. Though this was placed among the *Hartogias*, yet the flowers are hermaphrodite, but the fruit is three-celled. The horns of the germ are each of them terminated by two glands[g].

The Hottentots use the leaves of this species dried and powdered, under the name of Bucku, to mix with the grease with which they anoint themselves. It gives them so rank an odour, that Thunberg says, he sometimes could not bear the smell of the men who drove his waggon[h].

19. This is a small tree, six feet high, spreading and very much branched. Leaves quite entire, smooth. Flowers yellow, in compound racemes, anthers sessile, linear, at the side of the nectary, converging at top, capsules somewhat kidney-form, each on its proper peduncle. Seeds without any aril. Native of Cochinchina'.]

PROPAGATION AND CULTURE.

All these plants are propagated by cuttings, which may be planted during any of the summer months, in pots filled with light fresh earth, and plunged into a very moderate hot-bed, where they should be shaded in the day time from the sun, and frequently refreshed with water. In about two months the cuttings will have taken root, when they should be each transplanted into a small pot, and placed in a shady situation until the plants have taken fresh root, when they may be placed among other exotic plants, in a sheltered situation: these plants may remain abroad until the beginning of October or later, if the season continues favourable; for they only require to be sheltered from frost, so that in a dry airy green-house they may be preserved very well in winter, and in summer they may be exposed to the open air with other green-house plants.

The second sort frequently ripens its seed in England; but if the seeds are not sown soon after they are ripe, they rarely grow, or at least lie a whole year in the ground.

   Flowers twelve-stamened axillary, berries lenticular.
9. Diospyros tetrasperma.
   Swartz prodr. 62.
   Leaves membranaceous shining wedge-form, berries four-seeded.

DESCRIPTIONS, &c.

1. The smaller branches spread a little, and are yellowish. Leaves oval-lanceolate, large, quite entire, paler underneath, somewhat hoary, with the veins somewhat hairy. Flowers small, reddish-white, rotate. Fruit the size of a cherry, yellow when

[a] Linn. mant. [b] Linn. syst. & mant. [c] Linn. syst.
[d] Ibid. [e] Ibid. [f] Ibid. [g] Ibid.
[h] Travels, vol. 2. p. 187. engl. edit. [i] Loureiro.

when ripe, ſweet with aſtringency, ſeſſile in the boſom of the leaves, within the calyx which is increaſed, ſomewhat cartilaginous, flatted, uſually five-cleft, ſeldom four-cleft. Theſe berries are recommended as a cure for the diarrhœa[a].

Loureiro deſcribes it, as a ſmall tree, ſix feet high, with ſpreading branches. Leaves ovate-lanceolate, quite entire, large, alternate, ſmooth, with oblique prominent ribs. Flowers pale, terminating, ſolitary, with a very large leafy calyx, four or five-parted, flat, permanent. Berry round, half an inch in diameter, yellow, lanuginoſe, one-celled, containing eight oblong-compreſſed bony ſeeds, with very little pulp.

The broad-leaved variety grows up into very large trees in the ſouthern parts of Caucaſus. It is alſo abundantly native of the woods of Hyrcania and the whole coaſt of the Caſpian[b].

Geſner was informed that it grows on the mountains about Verona; and Mr. Ray is pretty confident that he ſaw it in his way from Lerici to Lucca, not far from the latter. In the woods on the hills about Turin, plentifully about Lyons, and on the eaſtern coaſt of Africa, whence it is ſuppoſed to have firſt come to Europe.

Mr. Miller has given the figure of the American ſort, which he has confounded with this[c]. He ſays it is a tree of middling growth in the ſouth of Europe, upwards of thirty feet high; particularly that there is a very old tree in the botanic garden at Padua, which produces plenty of fruit every year, and that many trees have been raiſed from the ſeeds of it; but that there are none of theſe trees in England, except what had been raiſed by him, from ſeeds which were ſent to him by the Chevalier Rathgeb, his imperial majeſty's miniſter at Venice. [He does not ſeem to have known that Gerarde had planted two trees of this ſort in the Earl of Eſſex's garden at Barne Elmes, that it was alſo growing in Gerarde's own garden, and in that of Maſter Graie an apothecary of London. Gerarde ſays, that in Engliſh it is called *Baſtard Meuynwood:* this name is now quite loſt. Parkinſon calls it Indian Date-Plum.

2. The wood of the American Date-Plum is very hard, but brittle and ſomewhat white; the branches are many, and grow ſlender to the end, covered with a very thin greeniſh bark. Leaves many, broad, green, without dent or notch on the edges, ſo like the former, that it ſeems to be the ſame[d]. Our European Lotus however, has a lighter coloured bark, on the branches inclining to yellow, on the twigs yellow and ſhining: the American has a dark brown bark on the branches, and on the twigs it is grayiſh from pubeſcence, ſo that they are ſoft to the touch, whereas the others are ſmooth. The leaves of the firſt are in general much narrower, leſs pointed, more ſhining on their upper ſurface, not pubeſcent on the under, but rather glaucous: thoſe of the ſecond are gray on the back, and pubeſcent, particularly the midrib and petiole. Fruit in form and bigneſs like a date, very firm like that fruit, and almoſt as ſweet, with a great flat thick kernel within, very like thoſe of the former, but larger[e].]

It riſes (in England) to the height of fourteen or ſixteen feet, but generally divides into many irregular trunks near the ground, ſo that it is very rare to ſee a handſome tree of this ſort. It produces plenty of fruit in England, but it never comes to perfection. [If it be eaten while it is green (as Captain Smith relates, in the diſcovery of Virginia) it draws the mouth awry by its harſh and binding taſte, but when ripe it is pleaſant[f]. This is not the caſe till it has been mellowed by the froſt; it is then very ſweet and glutinous, with a little aſtringency; and a conſiderable quantity may be eaten without inconvenience. In North America they make a palatable liquor with this fruit and malt; they alſo draw a ſpirit from it. The time of ripening is from the end of ſeptember to december. The wood of this tree is very good for joiner's tools, ſuch as planes, handles to chiſels, &c. but it ſoon rots if expoſed to the weather. It ſpreads very much, and is not eaſy to extirpate; but in the northern provinces of the American ſtates, it is often killed by froſt in hard winters[g].

In Virginia and Carolina there is great plenty of theſe trees in the woods: alſo in Penſylvania, Philadelphia, New Jerſey, &c. for the moſt part in wet places, round the water-pits. It is known there by the name of *Piſhamin* or *Perſimon*.

3. A middling ſized tree very branching. Branches and twigs alternate, round, dotted, ſmooth, tomentoſe at the ends ſpreading. Leaves alternate, petioled, ovate, acuminate, quite entire, paler underneath, ſcarce apparently villoſe, netted-nerved, ſmooth above, an inch or more in breadth, from an inch to three inches in length, ſpreading. Petioles ſemicylindric, ſubtomentoſe, half an inch long. Flowers axillary, peduncles tomentoſe, half an inch in length. Pedicels one-flowered like the peduncles. Perianth villoſe, diviſions ovate, acute, ſhorter than the corolla, which is ſubcampanulate; tube equal, diviſions ovate, obtuſe, reflex. Filaments very ſhort, inſerted into the baſe of the corolla. Anthers twin, as it were doubled, lanceolate, pale, erect, ſhorter than the corolla, approximating in a double row, villoſe, the inner ones a little ſhorter. Germ ſuperior, conic. Style ſubulate, erect, ſhorter than the calyx. Stigma briſtle-form and bifid. Fruit a ſubglobоſe pome, obſcurely four-cornered, ſmooth, when unripe green, when ripe yellow, truncate at the baſe, where the calyx remains, obtuſe with the ſtigma alſo permanent, eight-valved, eight-celled, the ſize of a middling apple, having nearly the taſte of a ſweet white plum, fleſhy. Seeds half-mooned, compreſſed at one edge, ſmooth. Some of the cells are ſometimes barren.

The fruit eaten plentifully occaſions a diarrhœa in the autumnal months. It is preſerved in the ſame manner as the fig, by ſprinkling meal or ſugar over it.

This genus ought certainly to be reduced to the claſs Octandria, for there is a ſtyle in all the flowers, though it is not always fertile; and all the flowers are hermaphrodite. Loureiro ſays, that trees of this ſpecies are ſometimes found, though ſeldom, with male flowers only.

β. There is a variety of this, in which the leaves are oblong-ovate, acute, nerved, a finger's length; the petioles channelled. Flowers alternate on the twigs, approximating, on ſuch ſhort peduncles as to be almoſt ſeſſile. Perianth green, ſpreading, permanent; diviſions bluntiſh, ſmooth. Germ marked with four or five ſtreaks: ſtyle very ſhort, four-cornered, whitiſh. Pome ovate, very obtuſe, yellow, with a ſoft aſtringent pulp like that of the orange; uſually eight-celled, ſometimes ten-celled, but very ſeldom nine-celled, the ſize of a pigeon's egg, always barren.

Native of Japan, and cultivated there[h]. Alſo in China, Cochinchina, and ſome parts of the Eaſt Indies[i]. It differs from the American ſort in its branches, and the pubeſcence on the lower ſurface of the leaves[k].

4. It differs from the foregoing in having the flowers ſeſſile and many together, and the leaves obtuſe at both ends, not acuminate. Found in Ceylon, by Thunberg[l].

5. This is a very large tree, very ſmooth in all its parts, the timber very hard. The ſmall branches have an aſh-coloured bark; thoſe which bear the leaves are blackiſh. Leaves alternate, on very ſhort petioles, quite entire, obtuſe, ſhining, often ſpotted, beneath wrinkled with ſmall veins, and as it were a little hoary. Berry ſeſſile, ovate, on the four-cleft, reflex calyx, ſeeds ſix to eight, ovate, black, ſomewhat compreſſed. It is very like the firſt ſpecies, but the leaves are more ovate, and more hoary underneath.—The wood is heavy, compact, and hard, whitiſh next the bark, but towards the middle very black;

[a] Pallas. [b] Ibid. [c] Parkinſon. [d] Ibid. [e] Ibid. [f] Kalm. [g] Thunberg. [h] Loureiro. [i] Linn. ſuppl. [k] Ibid. [l] Ibid.

black; this blackneſs gradually tinges the whole body, in the ſame manner as the reſinous part of the fir pervades the body by the decaying branches. This is the true Ebony, detected by Koenig, and confirmed by Thunberg.—Native of the vaſt woods of Ceylon[1], Amboina, Cochinchina, and the Eaſt Indies.

According to Retzius, this ſpecies is confounded with the next in the Supplement.

Loureiro deſcribes his D. decandra as a large tree, with the boughs ſomewhat ſpreading. Leaves ovate-lanceolate, quite entire, lanuginoſe, ſcattered, on ſhort petioles. Flowers white, axillary, in threes, on ſhort peduncles. Calyx four-parted, ſpreading, ſmall, permanent; with acute, thick, hairy ſegments. Corolla bell-ſhaped, with a pitcher-ſhaped tube drawn tight at the neck; border ſmall, four-cleft, obtuſe, reflex. Filaments conſtantly ten, fixed to the bottom of the corolla; with oblong ſtanding anthers. Germ roundiſh, ſuperior, with ſcarce any ſtyle, and three trifid, ſpreading ſtigmas. Berry large, ſubglobular, umbilicate, yellowiſh, pulpy, one-celled, with from ſix to eight ſeeds, which are bony, and of a compreſſed ovate form. According to Juſſieu, the fruit has from eight to twelve cells. Gærtner deſcribes the ſeeds as ſemi-ovate, wedge-form-compreſſed, ſlightly convex on one ſide, flat on the other, ſurrounded by a depreſſed line, of a ruſous ferruginous colour.

The fruit has an auſterity mixed with its ſweetneſs, and a ſtrong unpleaſant ſmell; it is however eaten, and ſold in the markets in the northern provinces of Cochinchina. The wood of this tree, when of a ſufficient age, is excellent for cabinets and all elegant works, being of a compact, fine, regular grain, heavy, very white veined with black, and ſometimes black at the heart[2]. It is not however the true Ebony; which is deſcribed by Loureiro (p. 613.) under the name of *Ebenoxylum*.

6. Leaves about three inches in length, thin, flexible, dark green.—Native of Ceylon. The foregoing was obſerved in the woods near Calcutta, by Koenig[3].

7. This is a ſmall tree, eight feet high, with ſpreading branches. Leaves ſmall, quite entire, pale green, petioled, alternate. Filaments always eight, with double anthers on each. Flowers white, hermaphrodite; tube four-cornered, ventricoſe; border ſmall, four-cleft. Style ſcarcely any; ſtigma oblong, deeply four-cleft. Berry pale yellow, an inch in diameter, compreſſed, eight-celled, one-ſeeded; with a ſweetiſh-auſtere pulp, without any ſmell.

8. This is a large tree. Leaves broad lanceolate, quite entire, alternate. Flowers white; tube ſubglobular, large; with a ſhort, four-cleft border. Stamens eighteen, placed on the bottom of the tube. Berry pale, compreſſed, ſhaped like a lens, one-celled, with eight compreſſed-ovate, bony, large ſeeds; the pulp is ſweetiſh, aſtringent, eatable but not pleaſant. The wood is like that of the falſe Ebony (n. 5.), but has not the black veins. This tree is much uſed for ſupporting the Black Pepper ſhrubs. Theſe are both natives of Cochinchina[4].

9. Native of Jamaica[5].]

PROPAGATION AND CULTURE.

1. 2. Theſe are both propagated by ſeeds, which will come up very well in the open ground; but if they are ſown upon a moderate hot-bed, the plants will come up much ſooner, and make a greater progreſs; but in this caſe the ſeeds ſhould be ſown in pots or boxes of earth, and plunged into the hot-bed, becauſe the plants will not bear tranſplanting till autumn, when the leaves fall off; ſo that when the plants are up, and have made ſome progreſs, they may be inured by degrees to the open air; and in June they may be wholly expoſed, and may remain abroad until november, when it will be proper to ſet the pots under a hot-bed frame to protect them from hard froſt, which, while they are very young, may kill the tops of the plants; but they muſt have as much free air as poſſible in mild weather. The following ſpring, before the plants begin to ſhoot, they ſhould be tranſplanted into a nurſery, in a warm ſituation, where they may be trained up for two years, and then removed to the places where they are deſigned to remain. Theſe are both hardy enough to reſiſt the greateſt cold of this country, after the plants have acquired ſtrength.

[The other ſpecies are natives of the Eaſt Indies and other hot climates; they require therefore the protection of the bark-ſtove. They have not however yet been introduced into cultivation here.

DIOTOTHECA. See *Morina*.

DIPHYSA (Απο του δις και τας φυσαις. *Jacqu. So called on account of the two bladders* (φυσα) *of the legume.*)

Lin. gen. Schreb. n. 1104. *Jacqu. amer.* 208. *Juſſ.* 362.

Claſſ. 17. 4. Diadelphia Decandria.

Nat. Order of *Papilionaceæ* or *Leguminoſæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, bell-ſhaped, ſlightly compreſſed, half-five-cleft: the two upper ſegments roundiſh, obtuſe, plane, ſpreading very much; the two lateral ones ovate, acute, erect, flattiſh; the loweſt lanceolate, acuminate, concave, erect, a little longer than the reſt.

COR. papilionaceous. *Standard* obovate-oblong, emarginate, plane, broad, reflex, on a claw the length of the calyx. *Wings* ſhorter than the ſtandard, oblong, obtuſe, aſcending, converging behind, diverging in front. *Keel* ſickle-ſhaped, acuminate, compreſſed, aſcending, ſhorter than the wings.

STAM. *Filaments* ten, diadelphous (ſimple and nine-cleft,) aſcending. *Anthers* ovate, ſmall.

PIST. *Germ* ſubcylindrical, pedicelled. *Style* capillary, riſing. *Stigma* ſimple, acute.

PER. *Legume* linear, compreſſed-flat, obtuſe, augmented longitudinally on each ſide by a membranaceous, very large, inflated bladder, cloſed all round; one-celled.

SEEDS ſeveral, oblong, obtuſe, compreſſed, furniſhed with a little hook.

OBS. *The future is common both to valve and bladder. The legume divides into joints between the ſeed.*

ESSENTIAL CHARACTER.

Cal. half-five-cleft. *Legume* with a bladder on each ſide. *Seeds* hooked.

SPECIES.

1. Diphyſa carthaginenſis.

Jacqu. amer. t. 208. *pict. t.* 261. *f.* 59.

DESCRIPTIONS, *&c.*

This is a ſmall unarmed inelegant erect branching tree, ten feet in height, and approaching to the arboreſcent Mimoſas. Leaves pinnate, ſmooth, two inches long, on the younger branches: there are uſually five leaflets on each ſide, with an odd one, though not unfrequently more or leſs; they are oblong, emarginate, ſmall, ſome alternate, others oppoſite. Common peduncles two-flowered or three-flowered, axillary, filiform, the length of the leaves. Flowers yellow, with ſcarcely any ſmell. Legumes have thin, dry, whitiſh bladders to them, whence the name. They continue long upon the tree without opening, till at length they fall in tranſverſe pieces at the joints. Seeds five or ſix, yellowiſh.

It grows every where about Carthagena in New Spain; and flowers in auguſt and ſeptember[6].]

DIPSACUS. (*Of Pliny.* Διψακες *of Dioſcorides. From* Διψαω, *ſitio*; διψακες, *is alſo the greek name for the diſeaſe which we call diabetes, and which is accompanied with great thirſt.*)

DESCRIPTIONS, &c.

Biennial, tall, herbaceous plants, prickly or rough, terminated by rough heads of flowers. The leaves ſometimes connate at the baſe, and forming a baſin containing rain.]

1. This is cultivated in great quantities in the weſt of England, for raiſing the nap upon woollen cloths, [by means of the crooked awns or chaffs upon the heads; which in the wild ſort are ſtraight, or at leaſt not hooked. For this purpoſe they are fixed round the circumference of a large broad wheel, which is made to turn round, and the cloth is held againſt them. Theſe heads are collected in auguſt[a]. Parkinſon calls it Fullers Thiſtle; and Gerarde, Tame or Garden Teaſel. In German it is named *Kardendiſtel*, *Weberdiſtel*, *Weberkrgrten*, *Karten*, *Kartetſchendiſtel*, *Wollerdiſtel*, *Tuchmacherdiſtel*, &c. In Dutch, *Vollers Kaarden*, *Kaarden* or *Kaardenkruid*. In Daniſh, *Kardethiſtel*, *Kradſetidſel*. In Swediſh, *Kardor*, *Kardtiſtel*. In French, *Chardon à foullon*, *à carder*, *à honnetier*; *Carderre à foullon*, *Cardiere*, *Cuve de Venus*, *bain de notre Dame*. In Italian, *Diſſaco*, *Cardo da cardare*, *Labbro di Venere*. In Spaniſh, *Cardenetha*, *Cardo peinador*. In Portugueze, *Cardo penteador*. In Ruſſian, *Sukonnaja*, *Tſchotka*.

2. *Root* biennial, ſimple, with large fibres. *Stem* from three to ſix feet high, branched, round, ſtriated, hollow, ſpinous, but the ſpines few near the baſe, very numerous near the heads, long and ſharp. *Root-leaves* of the firſt year's plant ſpread on the ground in a circular form, ovate-oblong, bluntiſh, notched, wrinkled, and rough with ſpines thinly ſcattered over the leaf: *ſtem leaves*, at leaſt the lowermoſt, leſs wrinkled, united at the baſe ſo as to form a large cavity containing water after rain, (hence the names of Dipſacus and Labrum Veneris); they are ovate-acute, notched, thinly beſet with ſpines on the edge and midrib: *uppermoſt* ſlightly united at the baſe, narrower, entire, and almoſt free from ſpines. *Heads* numerous, ſolitary, upright, ovate-oblong, ſomewhat pointed at top. *Flowers* blue-purple, firſt breaking forth about the middle of the head. Common perianth or involucre, compoſed of linear rigid leaves, beſet with ſmall ſpines, bending upwards, the length of the head, or longer, unequal. Calyx very minute, green, and edged with hairs. Corolla, tube whitiſh, and appearing ſlightly villoſe if magnified. Filaments ſtraight, inſerted into the tube of the corolla: anthers oblong, violet-coloured. Germ four-cornered, whitiſh, grooved: ſtyle a little longer than the corolla: ſtigma channelled and bent a little in. Chaffs of the receptacle the length of the ſtamens, rigid, bearded, the uppermoſt longeſt, at bottom hollow and ſomewhat triangular; the beard or awn running out to a long, ſtraight and ſomewhat hiſpid point[b]. Some of the lower chaffs are greatly bowed downwards, but not hooked at the point[c]. Native of moſt parts of Europe, on the edges of paſtures, in uncultivated places and by road ſides; flowering from june or july to ſeptember.

The water contained in the baſin formed by the leaves is ſaid to cure warts on the hands, and to ſerve as a beauty waſh for the face; hence Ray conjectures that this plant might have received its name of *Labrum Veneris*. It is alſo ſuppoſed to be good for the eyes.

Cattle in general, even the aſs, appear to avoid it. A ſmall moth, earwigs and other inſects, take refuge in the head[d].

Mr. Woodward ſays that he has not found it north of Nottinghamſhire and Derbyſhire. A friend however aſſures me that he remembers to have ſeen it about Newcaſtle, and Mr. Lightfoot mentions its being wild in Scotland.

According to Linnæus, the cultivated Teaſel is only a variety of the wild one. They certainly differ ſo little, that it was not neceſſary to deſcribe both. Haller, Jacquin and moſt modern authors are diſpoſed to conſider them as diſtinct. Mr. Miller, having cultivated both forty years, heſitates not to be of this opinion.

3. *Root* biennial, long, branching. *Stem* three feet high, upright, angular, prickly, branched. Leaves pinnatifid, laciniate or ſinuate, bright green, ſmooth above, pubeſcent beneath, having ſhort prickles along the nerve, and being ciliate on the edge. Heads ovate, obtuſe, terminating the ſtem and branches; with an involucre at the baſe conſiſting of ſtiff prickly leaves ſpreading out like a ſtar. Chaffs lanceolate, ſtraight, ending in a ſtiff prickle

[a] Withering. [b] Curtis. [c] Stokes in Withering. [d] Curtis.

Flowers

Flowers whitiſh. Anthers reddiſh[a]. It differs from the common Teaſel, not only in the leaves being cut ſo deeply, but in the prickles being weaker, and having lateral flowers, riſing higher than thoſe in the middle[b]. The Goldfinch is fond of the ſeeds; as it is alſo of our common ſort.—Native of Germany, France, Alſace, Auſtria, Carniola.—Cultivated 1683, by Mr. James Sutherland[c].

4. It differs from its congeners in having a fragile ſtem, from two feet high to ſix. Sharp with ſhort prickles pointing upwards, angular and grooved. Leaves with little appendages at the baſe; but theſe are ſometimes wanting; and the upper leaves are nearly entire, ſlightly hairy on both ſides, and with ſhort prickles along the midrib underneath.—Scales of the receptacle longer than the corollas, ending in hemiſpherical heads. Leaves of the common calyx or involucre linear-lanceolate, ending in a ſharp point, ſhorter than the head: theſe and the ſcales edged with long ſoft hairs. Corollas white, ſometimes with a purple tinge; anthers dark purple: ſeeds ovate-quadrangular, crowned with the calyx. Stigma ſometimes ſimple, but moſt frequently bifid, with the lower lobe ſhorter than the upper; as it is likewiſe in the common ſort: ſometimes it is ſlightly cloven into three parts. The heads of flowers hang down during the time of flowering, but afterwards become upright[d].

This plant is called *Shepherd's-rod* and *Shepherd's-ſtaff*. It flowers in july, and the ſeeds are ripe in ſeptember. They are eaten by ſmall birds; and the flowers are frequented by moths in great numbers, after ſun-ſet. It is the handſomeſt ſpecies of the genus, and very diſtinct from the three others, which are nearly allied. It is native of France, Germany, Switzerland, and Auſtria. With us, but not common in moiſt and watery places, by brooks and damp hedges and ditches: near London Mr. Curtis has found it only between Deptford and Lewiſham; Johnſon found it in great plenty at Edgecombe (Adſcombe) by Croydon in Surry; it occurs near Guildford, Godalmin, &c. in the ſame county.—It alſo grows in Beckenham church-yard, &c. in Kent, and in ſeveral other places in that county, as about Chiſlehurſt, Foot's-Cray, Farnborough, &c. about Finchley in Middleſex; Fulham between the Biſhop's palace and the field; More-hall, &c. near Harefield; it occurs in ſeveral places near Cambridge; near Thame park in Oxfordſhire; alſo at Lilleſhall Abbey in Shropſhire; Eveſham in Worceſterſhire. Gerarde remarked it in the way from Braintree to Hedingham, and from Dunmow to London.—Garanton Park and Hollinghall wood in Leiceſterſhire. Pleaſly forges, in Nottinghamſhire, and in Scotland.]

PROPAGATION AND CULTURE.

1. This plant is propagated by ſowing the ſeeds in march, upon a ſoil that has been well ploughed: about one peck of this ſeed will ſow an acre; for the plants ſhould have room to grow, otherwiſe the heads will not be ſo large, nor in ſo great quantity. When the plants are come up, hoe them in the ſame manner as is practiſed for Turneps, cutting down all the weeds, and ſingling out the plants to about ſix or eight inches diſtance; and as the plants advance, and the weeds begin to grow again, hoe them a ſecond time, cutting out the plants to a wider diſtance, for they ſhould be, at laſt, left at leaſt a foot aſunder: and you ſhould be particularly careful to clear them from weeds, eſpecially the firſt ſummer; for when the plants have ſpread ſo as to cover the ſurface of the ground, the weeds will not ſo readily grow between them. The ſecond year after ſowing, the plants will ſhoot up ſtalks with heads, which will be fit to cut about the beginning of auguſt; at which time they ſhould be cut, and tied up in bunches, ſetting them in the ſun if the weather be fair; but if not, they muſt be ſet in rooms to dry. The common produce is about an hundred and ſixty bundles or ſlaves upon an acre, which they ſell for about one ſhilling a ſlave. Some people ſow Caraway and other ſeeds among their Teaſels, but this is not a good method, for the one ſpoils the other; nor can you ſo eaſily clear them from weeds as when alone[e].

[This however is ſtill the common practice in Eſſex, where the Teaſel is chiefly cultivated, on account of the neighbouring manufactures of ordinary cloth and baize, in which it is uſed for raiſing the nap.

Old paſture land, the ſoil of which is a ſtrong claycy loom, is beſt adopted to the culture of Teaſel. The method of managing the land for their compound crop, has been already given under the article Carum or Cataway. We have only to add therefore, for the inſtruction of the hoers, that the firſt appearance of Teaſel is much like that of a lettuce; that the heads being ready about the middle of ſeptember the ſecond year, are to be cut as ſoon as they begin to turn brown, with a ſtalk a foot long, and tied up in bundles or bunches, twenty-five in each; twenty-four of theſe bunches are fixed on a ſmall ſtick, and called a row, two hundred and forty of which make a load in bulk, equal to a ton of hay from the meadow.

The work of cutting and bunching the Teaſel can only be done by thoſe, who are well acquainted with it. The crop muſt be looked over, and the heads cut at ſeveral times as they ripen. The produce is ſometimes a load on an acre, the average price of which is twelve pounds. But often there is not more than one fourth of a load[f].

2. Dipteryx oppoſitifolia. *Taralea. Aubl. pl. gui. p.* 745. *t.* 298. *Leaves oppoſite.*

DESCRIPTIONS, &c.

1. This is a large tree, ſixty feet high, very much branched at top. The leaves are large, alternate, and pinnate: the leaflets perfectly entire, two or three on each ſide, affixed alternately on the midrib. The flowers are borne in racemes, which are axillary and terminal. Their colour is purple, daſhed with violet. The almonds or fruits are fragrant, and are put by the Creoles into cheſts, in order to drive away inſects, as well as for the ſake of their ſmell. It grows in the large foreſts of Guiana.

2. This, like the former, is a tall tree, and very branchy at top. The leaves are oppoſite, and pinnate: the leaflets large, ovate, ſharp, ſtrong, and perfectly entire. The flowers are panicled, ax-

DESCRIPTION, &c.

Height five or ſix feet, but in Europe rarely more than half ſo high. It ſends out many jointed branches near the root. Leaves oval, pale yelloviſh, and ſmooth. The flowers come out from the ſide of the branches, two or three upon each peduncle; they are of a greeniſh white colour, and appear early in the ſpring, when the leaves begin to ſhoot.

[It is a little ſhrub growing on hills towards ſwamps and marſhes in North America. The bark is very tough, as is alſo the ſhrub itſelf, inſomuch that the branches cannot eaſily be ſeparated without cutting. The twigs are uſed for rods, and the bark for ropes, baſkets, &c. for which it is very fit, being equal in ſtrength and toughneſs to the bark of the lime tree. The French in Canada call it *Bois de Plomb* or Leaden-wood[a].

Introduced in 1750, by Archibald Duke of Argyle. It flowers in march and april[b].]

PROPAGATION AND CULTURE.

This ſhrub is very difficult to propagate in Europe, for as it does not produce ſeeds here, it can only be increaſed by layers or cuttings, and theſe are generally two years before they put out roots: and as it grows naturally in very moiſt places, it is with difficulty preſerved in gardens, unleſs it be planted in wet ground: it is ſeldom injured by cold.

DESCRIPTIONS, &c.

1. Stems from a foot to two feet in height, proſtrate, round, pubeſcent. Leaves alternate, petioled, with about thirty notches, pubeſcent. Peduncles axillary, uſually two together, but ſometimes one or three, erect, filiform, one-flowered, higher than the petioles. Corollas yellow[a]. The foliage greatly reſembles that of ground-ivy, and the branches trail

[a] Kalm. [b] Hort. kew.

[a] Lin. ſuppl. [a] Lin. ſyſt.

on the ground somewhat in the same manner to the length of several feet.—It varies extremely in the number of stamens, and in the divisions of the calyx and corolla[a]. Seven is thought to be the most prevalent number of stamens, and five the most natural[b]. Native of Madeira, and introduced about 1731[c]. It flowers most part of the summer[d].

2. It is doubtful whether this be a distinct species. The parts of the flower are very inconstant in their number: seven is the most frequent; five the most natural, but most seldom seen, especially in the cultivated plant. Native of Africa[e].

PROPAGATION AND CULTURE.

1. It grows readily from cuttings. In the winter it must be kept in the greenhouse, in the summer it will bear the open air. It should be planted in rich earth, and plentifully watered in dry weather. It appears best in a pot placed on a pedestal, or in some elevated situation, where its branches may hang carelessly down[f].

[2. Dodartia indica.

Lin. spec. 883. *Reich.* 3. 186.

Leaves ovate serrate villose.]

DESCRIPTIONS, &c.

1. It has a perennial root, which creeps far under the surface, and sends out new stalks at a great distance from the parent plant; these stalks are firm, a little compressed, and grow a foot and half high, sending out several side branches. Leaves long, narrow, fleshy, opposite, of a deep green colour; those on the lower part of the stalk are shorter and broader than those above; those on the upper part of the stalk are entire; at these joints the flowers come out singly on each side the stalk, sitting close to it; they are near an inch long. The flower is of a deep purple colour, and appears in July, but rarely produces seeds in England.

[a] Curtis. [b] Murray. [c] Hort. kew. [d] Linn. syst. [e] Curtis.

[The elegant Tournefort first discovered this plant near Corvirap in Armenia, not far from the foot of mount Ararat, on the 9th of august, 1700; and named it after Mons. Dodart, Physician to the Princess Dowager of Conti, one of the most learned men of that time, as he says, and no less esteemed for his modesty, than the purity of his manners. He thus describes it. Stem a foot and half high, straight, firm, smooth, woody, bright green, branched from the bottom and forming a round bush. Leaves an inch or fifteen lines in length, two or three lines wide, a little fleshy, toothed on the edge, especially the lower ones, for they are smaller towards the top of the plant and less toothed. Flowers axillary, towards the end of the branches, of a deep violet colour, eight or nine lines in length, tube a line in diameter, ending in two lips, the upper shaped like the bowl of a spoon, a line and half in length, cut into two pointed segments, the lower three lines long, rather rounded, but cut into three parts, of which the middle one is the smallest and most pointed: this lip is downy and towards the middle has some white hairs.

Linneus observes, that the flowers are alternate, racemed, and subsessile[a]. Capsule membranaceous, thin, scored on each side, seldom opening spontaneously. Seeds angular, smooth, cinereous-brown[b]. Cultivated 1739, by Mr. Miller[c].

2. Stems roundish, villose, somewhat branching. Leaves petioled, obtusely serrate. Raceme terminating with small leaves. Flowers opposite, pointing one way, subsessile. Calyx obtuse, villose. Corolla yellow, with the outer lip straight and short.—Native of India[d].]

PROPAGATION AND CULTURE.

1. It propagates very fast by its creeping roots, so that when it is once established in a garden, it will multiply fast enough; it loves a light dry soil, and may be transplanted either in autumn when the stalks decay, or in the spring before the new stalks arise.

   Auricula ursi virginiana, &c. *Pluk. alm. t.* 79. *f.* 6.

DESCRIPTION, *&c.*

Meadia has a yellow perennial root, from which come out in the spring several long smooth leaves, near six inches long, and two and a half broad; at first standing erect, but afterwards spreading on the ground, especially if it be much exposed to the sun: from among these leaves arise two, three, or four flower-stalks, in proportion to the strength of the roots, which rise eight or nine inches high; they are smooth, naked, and terminated by an umbel of flowers, which are purple, inclining to a peach-blossom colour. These appear at the end of april or the beginning of may; and the seeds ripen in july; soon after which the stalks and leaves decay, and the roots remain inactive till the following spring. [Each flower has a long slender peduncle, which is recurved, so that the flowers hang down[b]. The capsule is of the substance of paper, rufescent. Receptacle columnar, pedicelled, from round acuminate, with excavations on it. Seeds ovate-rounded, turgidly lenticular, somewhat wrinkled, yellow-rufescent. Umbilicus in the middle of the belly, obscure[c].]

It is a native of Virginia, and other parts of North America, whence it was sent by Banister, to Bishop Compton, in whose curious garden at Fulham Mr. Miller first saw it growing in the year 1709; after which this plant was lost for several years in England, till it was again obtained from America [by Mr. Catesby, and cultivated in 1744, by Peter Collinson, Esq.[d]] since which it has been propagated in great plenty. Mr. Mark Catesby named it Meadia, in honour of Dr. Richard Mead, who was a generous encourager of every branch of science, though no great botanist himself. [If we look over the list of those who have had plants named from them, we shall find many of very inferior note; and several who could produce no title to that honour, except their patronage of learning and learned men. Would not Linnæus therefore have done better to leave the name of this illustrious physician, and elegant scholar, as a generic term to this elegant plant; than to select a whimsical name from Pliny, and to affix it to an american plant, which Pliny could not ever have seen? Meadia however remains as the specific name, and the common appellation in England.]

PROPAGATION AND CULTURE.

This plant is propagated by offsets, which the roots put out pretty freely when they are in a loose moist soil and a shady situation; the best time to remove the roots, and take away the offsets, is in august, after the leaves and stalks are decayed, that they may be fixed well in their new situation before the frost comes on. It may also be propagated by seeds, which the plants generally produce in plenty; these should be sown in the autumn soon after they are ripe, either in a shady moist border, or in pots, which should be placed in the shade; in the spring the plants will come up, and must then be kept clean from weeds, and if the season proves dry, they must be frequently refreshed with water; nor should they be exposed to the sun, for while the plants are young, they are very impatient of heat, so that I have known great numbers of them destroyed in two or three days, which were growing to the full sun. These young plants should not be transplanted till their leaves are decayed, then they may be carefully taken up and planted in a shady border, where the soil is loose and moist, at about eight inches distance from each other, which will be room enough for them to grow one year, by which time they will be strong enough to produce flowers, and may then be transplanted into some shady borders in the flower-garden, where they will appear very ornamental during the continuance of their flowers.

At the first many supposed this plant to be tender, and planted it in warm situations and nursed it too much, whereby the plants were often killed; but by experience it is found to be so hardy, as not to be hurt by the severest cold of this country; but it will not thrive in a very dry soil, or where it is greatly exposed to the sun.

DESCRIP-

[a] Linn. suppl. [b] Mill. fig. [c] Gærtner. [d] Hort. kew.

DESCRIPTIONS, &c.

1. This ſends up ſeveral ſtalks from the root, about the ſize of a man's arm, with ſeveral upright branches, covered with a light brown bark, which frequently ſeparates from the wood, and hangs looſe; leaves ſtiff, varying greatly in ſhape and ſize, ſome being four inches long, and an inch and a half broad; others not three inches long, and a quarter of an inch broad; they are ſpear-ſhaped, entire, and of a light green, growing with their points upward, and have very ſhort foot-ſtalks. The flowers are produced at the end of the branches in a ſort of raceme, each ſtanding upon a ſlender foot-ſtalk about an inch long.

[This upright, branched ſhrub, growing about five feet in height, is entirely viſcid and fetid. The younger branches are angular. Leaves oblong, with a bluntiſh point, attenuated at the baſe, quite entire, alternate, with ſcarcely any petiole, on tender plants that come out in the firſt months, uſually repand or ſerrate. Flowers in racemes, frequently varying much on the ſame branches. The natural number of leaflets in the calyx ſeems to be four; it is ſeldom found with five, and when it has only three, which is frequently the caſe, one of the leaflets is always larger than the reſt, and ſcored with a longitudinal groove. The piſtil is frequently deficient in one third part, and then the capſule has only two cells. Sometimes there are only ſeven ſtamens, and even ſix, but that happens very ſeldom. One ſeed in a cell is frequently abortive, and ſometimes both [a].

According to Gærtner, the capſule is membranaceous, thin, netted with veins, two-celled or three-celled, three-valved: the valves boat-ſhaped, the keel widened out into a membranaceous, broad, rounded edge; partitions faſtened to the axis of the fruit, which continues after the valves have fallen off; it is three-ſided, and the ſeeds are fixed to the middle of it by two very ſmall tubercles. Seeds roundiſh, turgidly lenticular, but very ſharp-edged towards the back, hard, ſmooth, black.

Browne ſays that this ſlender ſhrub ſeldom riſes more than ſix or ſeven feet, (ten or twelve, *Sloane*); both the trunk and branches are very flexile and tapering. The taſte of the whole plant is acerb and bitteriſh. In Jamaica it is called the *Switch Sorrel*. Native of the countries between the tropics.

In the Society iſles it is dioecous, in New Zealand hermaphrodite [b].—Introduced in 1690 by Mr. Bentick [c].

2. This reſembles the foregoing, but the leaves are lanceolate-linear. The fructification is polygamous [d]. Native of the Cape of Good Hope. Cultivated 1758, by Mr. Miller. It flowers from may to auguſt [e].]

PROPAGATION AND CULTURE.

1. This plant is propagated by ſeeds, which, if obtained freſh from abroad, will riſe eaſily upon a hot-bed: when the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with light loamy earth, and plunged into a hot-bed of tanners' bark, ſhading them from the ſun till they have taken new root; then they ſhould have free air admitted to them every day in proportion to the warmth of the ſeaſon, for they muſt not be drawn up weak, nor ſhould they have too much water. In the autumn the plants muſt be removed into the ſtove, where they ſhould have a temperate warmth in winter, but during that ſeaſon little water ſhould be given them; nor ſhould they have too much heat, for either of theſe will ſoon deſtroy them: as the plants obtain ſtrength, they will become more hardy, and may be ſet abroad in the open air for two or three months in the heat of ſummer, but it ſhould be in a ſheltered ſituation; in winter they muſt be placed in a ſtove, kept to a moderate temperature of warmth, for the plants will not live in a green-houſe here.

This was formerly ſhewn for the Tea-tree in many of the European gardens, where it many years paſſed for it among thoſe who knew no better.

[2. The ſecond ſort is leſs tender, and requires only the protection of a green-houſe or glaſs caſe.

DOLICHOS. (Δολιχος *of Theophraſtus. From* δολιχος, *long; the pod or legume being generally lengthened out.*)
Lin. gen. n. 867. *Reich.* 941. *Schreb.* 1181. *Gærtn. t.* 150. *Juſſ.* 356.
Claſſ. 17. 4. Diadelphia Decandria.
Nat. order of *Papilionaceæ* or *Leguminoſæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, very ſhort, four-toothed, equal; the *ſuperior tooth* emarginate.

COR. papilionaceous.
Standard roundiſh, large, emarginate, the whole reflex. Two *calluſes* oblong, parallel and longitudinal, growing to the ſtandard beneath towards the baſe, compreſſing the wings, not hollowed on the back.
Wings ovate, obtuſe, length of the keel.
Keel lunulate, compreſſed, beneath converging cloſely, length of the wings, aſcending at the tip.

STAM. *Filaments* diadelphous, (ſimple and nine-cleft,) the *ſimple* one curved at the baſe. *Authers* ſimple.

PIST. *Germ* linear, compreſſed; *Style* aſcending. *Stigma* bearded, running on inwardly from the middle to the tip of the ſtyle, which on the fore part is callous, obtuſe.

PER. *Legume* acuminate, large, oblong, two-valved, two-celled.

SEEDS ſeveral, elliptic, uſually compreſſed.

OBS. *The habit is that of* Phaſeolus; *the Keel, which is not ſpiral, diſtinguiſhes the genus.*

ESSENTIAL CHARACTER.

Two parallel, oblong calluſes at the baſe of the ſtandard, compreſſing the wings underneath.

SPECIES.

* *Twining.*

Stem erect, angular, leaves villoſe, glaucous, legumes ſtiff and ſtraight, ſubquadrangular.

DESCRIPTION, *&c.*

Moſt of the ſpecies are annual, and natives either of the Eaſt or Weſt-Indies.—They are chiefly herbaceous, and furniſhed with twining ſtalks. The leaves are ternate and petioled, with ſtipules diſtinct from the petiole: the end-leaflets are jointed with the terminating petiolule, two-awned below; the ſide ones have only one awn; the awns reſemble ſtipules: the flowers are frequently in ſpikes, and axillary: the legume is often ſmooth, ſometimes but ſeldom villoſe or prurient. The lobes of the corcle are diſtinct from the ſeed-leaves [a]. The ſpecies are numerous. Mr. Miller affirms that he has cultivated more than ſixty, beſides many varieties, and ſuch probably are ſeveral which are reputed to be ſpecies. Some of them, wanting the calluſes, ſhould perhaps be removed to another genus. See *Teramnus*. Gærtner ſays, that the ſpecies may be more accurately determined, by obſerving whether the ſeed has any hilum (eye or umbilical ſcar,) and if it has, whether it is placed on one ſide, or annular.

1. This is a perennial, with a ſtem ſomewhat roughiſh to the touch, and ſcandent, as well as producing ſeveral branches: leaves roundiſh-ovate, ending in a point, furniſhed with a briſtle: ſtipules lanceolate; peduncles racemoſe, four or five inches long; flowers ſeated on very ſhort peduncles, uncertain as to number; ſnow-white, and ſlightly odorous: Legume oblong, pointed, compreſſed, firſt green, afterwards growing pale: ſeeds few, roundiſh-oblong, compreſſed, brown, with deeper-coloured points, and with a long protuberant, ſnow-white hilum [b].

2. Legumes ſcabrous at the back [c], compreſſed, flat, crenulate at both ſutures, conſiſting of ſeveral cells: partitions very thin, compoſed of a cellular ſnowy-white membrane. Seeds three or five, flatted a little, ſmooth, but not ſhining, black or ferruginous, edged on one ſide with a ſungoſe ſnowy-white callus, proceeding from the umbilicus: they have no albumen: the embryo is curved and white: the cotyledons elliptic and plano-convex; the plume two-leaved, the leaflets cordate-acuminate, veined, doubled together; the radicle bent in, and centrifugal [d]. Stems and branches round, ſcabrous backward. Peduncles forming half whorls [e].

Dolichos enſiformis of Thunberg approaches nearer to this, than to the D. enſiformis of Linneus, from which it is certainly different [f].

Alpinus ſays that this grows wild in Egypt. Haſſelquiſt, however, is certain that it does not grow wild in Lower Egypt, but is only cultivated there in gardens. The Egyptians call it *Fuel Frangi* or European Bean: hence we might conjecture that the Europeans firſt brought it into Egypt. The inhabitants make pleaſant arbours of it: they not only ſupport it with treilis work, but faſten it with twine, by which means the leaves form an excellent covering, and an agreeable ſhade.

It was cultivated in 1714, by the Dutcheſs of Beaufort [g].

3. Stem annual, long, round, ſlender, twining, ſomewhat branched. Leaves ternate, broad-lanceolate, ſmooth, with two or three lanceolate ſtipules at the baſe of the common petiole. Flowers pale violet, on few-flowered, ſuberect, axillary peduncles: ſtandard aſcending, very blunt. Legume linear, from one to two feet in length, ſubcylindric, toruloſe, ſmooth, pendulous. Seeds oblong-kidney-form, pale, many [h]. Loureiro is of opinion, that D. ſeſquipedalis, n. 28. is not different from this.

Native of India, Amboina, China and Cochinchina.—Introduced 1776, by M. Thouin.

[a] Juſſieu. [b] Jacqu. hort. [c] Linn. ſpec. [d] Gærtner. [e] Linn. ſpec. [f] Kæmpf. ic. ſelect. [g] Hort. kew. [h] Loureiro.

4. This is removed by Browne and Swartz to a new genus, under the name of Teramnus, becauſe it wants the calluſes at the baſe of the ſtandard in the corolla, and differs in other reſpects. See *Teramnus*. It is a native of Jamaica.

5. Stem rather angular, branches round; a ſcandent plant: branches three or four cubits long: leaves ovate, entire, ſubacute, gloſſy. Stipules ſmall and roundiſh: peduncles axillary, ſupporting from ſix to ten elegantly yellow flowers: the ſtigma is much bearded; the legume ſmooth and obtuſe [i]. Native of the Society iſles [k].

6. An annual ſmooth plant, with climbing ſtem: leaves lanced-ovate, and ſharp; peduncles ſupporting but few flowers, and upright; flowers whitiſh. Stigma long and bearded: legume ſmooth, ending in a recurved ſharp-pointed tip, which is channelled on its upper part. Seed whitiſh, with a ſnow-white hilum [l].

Native of the Weſt-Indies. Introduced 1780, by W. Ph. Perrin, Eſq. [m]. Loureiro ſays, it is a native of China, whence it was brought into Portugal.

7. This is extremely like the Dolichos unguiculatus, but flowers at a different time of the year, and is more climbing. The whole plant is very ſmooth: the vexillum or ſtandard of the flowers is pale yellow behind, and blueiſh-red in front; the wings more blue, and the keel white. The legume differs from that of the unguiculatus merely in being ſlenderer [n].

8. This is a native of Jamaica, and is diſtinguiſhed by its large falcated legume, and white ſeeds, with a ſaffron-coloured hile. The ſtem is three or four feet high: the ſhoots run much farther: the legumes are between ten and fourteen inches in length, and generally contain ten or eleven ſeeds [o].

9. Stem herbaceous, round, ſlender, ſcandent, long, branching. Leaflets broad-lanceolate, ſmooth, pale green: ſtipules lanceolate, minute. Flowers pale blue, on long, lateral, few-flowered peduncles. Legume thick, half a foot long, with a thin, lacerated, connate membrane at each of the four corners. Seeds about eight [p]. Native of the Eaſt-Indies, China and Cochinchina.

10. Appearance of a Phaſeolus. Standard of the flower pale above, reddiſh within. Legume more than a foot and half in length, roundiſh, with a little obtuſe gibbous hook at the end [q].—Native of the Weſt-Indies. Introduced 1781, by Mr. Francis Maſſon [r].

11. This climbs the higheſt trees, whence hang elegant wreaths of flowers in cloſe racemes, on peduncles frequently more than twelve feet in length. The proper pedicels are ſhort, and in threes: the flowers void of ſcent, an inch and half long, with a ferruginous calyx, a violet-blue ſtandard and wings, and a yellowiſh keel; the whole of the ſtamens and piſtil riſe ſurpriſingly, and are incloſed within the convoluted ſtandard. Native of the iſland of Martinico [s].

Loureiro applies Rumphius's ſynonym of Cacara perennis, t. 136, which Linneus gives to D. lignoſus (ſee n. 25.), to his D. altiſſimus; which he ſays agrees better, if the perennial ſtalk be excepted, with the altiſſimus of Linneus than with the lignoſus: he ſuſpects that this and the lignoſus may not be ſpecifically different.

12. Leaflets rough with hairs underneath. Calyx campanulate, five-toothed, the middle tooth ſhorter. Banner very ſhort, three times leſs than the other petals, ovate: keel linear, acute, boat-ſhaped at the end. Four alternate filaments, ſomewhat club-ſhaped, larger. Legume compreſſed, inflex at the baſe, reflex at the tip [t].

Common in all parts of the Weſt-Indies, and riſing to the top of the talleſt trees, or ſpreading

[i] Jacqu. hort. [k] Forſter. [l] Jacqu. hort. [m] Hort. kew. [n] Jacqu. hort. [o] Linn. hort. cliff. and Brown. jam. [p] Loureiro. [q] Linn. ſpec. [r] Hort. kew. [s] Jacqu. amer. [t] Linn. amen.

wide among lower buſhes. Stems round and ſlender. Leaflets oval and villoſe, always three on every foot-ſtalk. Flowers dark purple, in ſpikes at the axils of the ribs. Legumes beſet thickly with ſhort, rigid hairs, occaſioning an itching when handled. A decoction of the roots is reckoned a powerful diuretic, and cleanſer of the kidneys. A vinous infuſion of the pods (twelve to a quart) is ſaid to be a certain remedy for the dropſy: the doſe half a pint, when made in beer. In the Windward iſlands, they make a ſyrup of the pods, which is ſaid to be very effectual againſt worms [a].—Native of both Indies, according to Linneus, and of Cochinchina, according to Loureiro. Introduced in 1781, by Mr. Gilbert Alexander [b].—This may be true of the Kew garden; but had it not been cultivated before by Mr. Miller and others?

13. Stems round. Leaflets ſubovate, quite entire, acuminate, the upper ſurface ſmooth, the lower covered with a ſhining ſilvery down that is hardly perceptible. Racemes ſimple, pendulous, ſcarcely ever longer than the leaves. Proper peduncles one-flowered, in threes, placed cloſely at the end of the raceme, and hence forming a very elegant pendulous wreath of about eighteen flowers; theſe have no ſcent, are about two inches long, have a ferruginous calyx, and a yellow corolla, with the lower edge of the wings red. Legume ſeven inches long, wrinkled. The ſeeds, from their reſemblance to an eye, are called by the French *Yeux bourrique*, or Aſs's eye [c]. In our Weſt-India iſlands, for the ſame reaſon, they have the name of *Ox-eye Bean*.

This alſo climbs to the top of the talleſt trees, throwing down its long ſlender flower-ſtalks to a moderate diſtance from the axils of the upper ribs, from whence they generally riſe: theſe are not above the thickneſs of a common packthread, but ſeldom under four or five feet in length, and bear the flowers in cluſters at their extremities [d]. Jacquin, however, thinks it probable, that by this deſcription Browne may have confounded this ſpecies with the altiſſimus.

Native of the Weſt-Indies. Cultivated 1691, by the Dutcheſs of Beaufort [e]. This and the foregoing are perennial and ſhrubby. The ſurface alſo of the legumes are covered with prurient hairs.

14. This climbs three or four feet in height, and has numerous branches. Leaves glaucous. Racemes ſtiff. Wings of the corolla yellow; ſtandard brownith red, turning blue as it withers. Legumes villoſe and brown, commonly containing only two ſeeds. According to Linneus there are four [f]. Browne calls it ſmall fetid Dolichos. In Curaçoa it has the name of *Vraitekruyt* or Wart-herb, the leaves bruiſed with ſalt, being reputed to cure warts.

Native of Jamaica, and according to Jacquin of all the Caribbee iſlands. Introduced 1776, by Monſ. Thouin [g].

15. Stem ſubangular, ſmooth. Leaflets ſmooth, ovate, obtuſe with a point, marked with lines, equal, an inch and half in length, the ſide ones on ſhort, the middle one on a long petiole. Stipules very ſmall, briſtle-form. Legumes rounded in front, ſtraight at the back, marked with three lines, the ſide ones larger than the middle line, acute, ſmooth, two inches long.—It differs from *D. enſiformis* in the leaves being ovate-oblong, not gibbous; obtuſe, not acute; thick, and marked with lines, not three-nerved: in having the legumes ſtraight at the back and oblong, not ſcymitar-ſhaped and curled. Native of Japan [h]. Thunberg aſcribes the *Reedſa* of Kæmpf. amoen. 5. 836. to this ſpecies. See n. 32.

16. Stem filiform, angular, even. Stipules ovate, acute, ſtriated, very ſmall. Leaves petioled; leaflets ovate-oblong, acuminate, veined. Peduncles long. Legumes acute at both ends, the back future ſtraighteſt, ſmooth, containing uſually two ſeeds [i]. Native of the Cape of Good Hope.

17. Stem ſcabrous. Leaves petioled; leaflets obtuſe, veined underneath, ſoft. Flowers ſingle from the axils. The ſeeds have two proceſſes like the antennæ of a beetle, whence the name [k]. Native of the Eaſt-Indies. Introduced 1773, by Joſ. Nath. de Jacquin, M. D. [l].

18. Stem ſtriated, ſmooth. Leaflets oblong, acute, entire, ſmooth, paler underneath, nerved, two inches broad, a hand in length, equal; the ſide ones on very ſhort petioles, the middle leaflet on a longer. Flowers axillary, ſolitary, peduncled. Peduncle round, bent round at the end, and ſmooth. Legume enſiform, with a point at the end bent in, ſmooth, a ſhort ſpan in length.—It differs from *D. enſiformis* in having the flowers ſolitary from the axils; the leaves oblong, and not gibbous on one ſide; the legumes bent in, not ſcymitar-ſhaped, and bent back; and the peduncle bending round:—from *D. lineatus*, in the leaves being broad at the baſe, gradually acuminate, three-nerved, thinner; the legume inflex, enſiform, acuminate, waved, ſolitary. Native of Japan [m].

19. Stem perennial, ſuffruticoſe, long, round, ſmooth, branched, without any ſtipules. Leaves roundiſh-angular, ternate, acuminate, petioled. Flowers terminating, in long racemes. Calyx cup-ſhaped, four-cleft, the upper ſegment ſhorter, emarginate. Corolla pale violet, with an ovate, entire, converging ſtandard. Legume compreſſed, linear, four inches long, ſlightly bowed, divided acroſs. The root conſiſts of roundiſh, tailed, juicy, white tubers in bundles: theſe are eaten both raw and dreſſed, but not the ſeeds [n].

Native of both Indies. Introduced 1781, by Mr. Francis Maſſon [o].

20. Stem perennial, ſuffruticoſe, round, very long, branched, twining or creeping when it lies on the ground, hirſute. Leaves petioled, with two-horned ſtipules: leaflets three-lobed, acuminate, pubeſcent. Flowers purple, in long terminating and lateral ſpikes; with a large yellow ſpot on the middle of the ſtandard. Legume four inches long, linear, ſtraight, compreſſed, divided acroſs between the ſeeds, which are about eight in number, and of a rufous colour. The root is compoſed of a few long tubers in bundles, they are two feet long, ſubcylindric, fibroſe-fleſhy, of a pale colour, and eatable when boiled; but not the legumes [p]. Loureiro doubts whether this be the plant of Plukenet and Burman, ſince theſe authors make no mention of the remarkable large tubers.

Native of the Eaſt-Indies. Cultivated in China and Cochinchina.

21. Stem round. Leaflets even, ovate-oblong, acuminate. Legumes ſtraight and ſtiff, ending in a filiform, ſtiff, ſharp awn, an inch in length. Native of America [q].

22. This grows among buſhes, but ſeldom ſtretches above three or four feet in length. The pods are long and compreſſed; the ſtigma or top of the ſtyle is almoſt naked. It is uſed as a purgative ingredient in diet-drinks, and is ſaid to anſwer well in hydropic caſes. Native of Jamaica, where it is called Cat's-claws [r].

23. Stem purpliſh. Leaflets ſubcordate, ſmooth, netted underneath with purple veins. Calyxes covered with two bractes. Corolla bright purple: keel violet below the tip. Legume compreſſed [s]. Loureiro adds, that the ſtem is perennial, biſpid, and branched: the leaflets ſharp, ſhort, with purple veins, on hairy petioles: ſtipules in fours, awl-ſhaped: the calyx of the ſame colour with the corolla: the flowers in long, erect, terminating ſpikes: legumes three inches long, broad and flat, ſmooth, purpliſh: ſeeds compreſſed-ovate, ſurrounded with a ſcar. The legumes, when young and freſh, are ſapid and ſalubrious. Native of both Indies. Cultivated in China and Cochinchina.

q Loureiro.
r Linn. ſpec.

Loureiro has another ſort, which he calls *D. albus*, and is not very different from this, only more tender and ſapid. It is *Cacara alba* of Rumphius, 5. t. 137. The ſtem is ſmooth and white: the leaflets three-cornered-rounded, pubeſcent, ſoft, pale, on ſmooth petioles: ſtipules in pairs, acute, ſhort: flowers white, in ſhort ſubterminating racemes, with a very wide, reflex ſtandard: legumes ſmooth, but tubercled on the back, and beaked. This is alſo cultivated in China and Cochinchina.

24. Native of Virginia.

25. Root woody, perennial. Stem woody, ſupple, much branched, roundiſh, ſtriated, ſmooth: branches alternate, very long and ſlender, but little ſubdivided, round, ſtriated, ſomewhat downy, leafy, many-flowered. Leaves alternate, on long foot-ſtalks, ternate or rather binate with an odd leaflet: common foot-ſtalk roundiſh, channelled above, ſwelling and purpliſh at the baſe; partial ones very ſhort, ſwelled, incurved: leaflets rhomboid, elongated, acute, entire, obſoletely three-nerved; bright green and ſhining above, glaucous beneath. Stipules entire, ſharp, ſomewhat triangular, downy on the margin, dark purple at the baſe, two larger at the bottom of the common foot-ſtalk, and two ſmaller, lanceolate at the inſertion of the partial foot-ſtalks. Racemes axillary, ſolitary, erect, having from three to ſix flowers in a little head. Peduncle ſimple, very long, ſtriated, angular in the upper part; pedicels generally two together, ſhort, downy, one-flowered. Bractes lanceolate, acute, hairy. Flowers nodding a little, roſe-coloured with a purpliſh keel. Calyx ſmooth, thickly ciliated on the edge. Legume an inch long, a little recurved, browniſh, ſmooth. Seeds black [b].

Native of the Eaſt Indies. Introduced 1776, by M. Thouin [b].

26. Stem becoming ſhrubby, often round, ſmooth, very long. Leaves alternate, unequally pinnate, ſmooth: leaflets about ſix pairs, oppoſite, on very ſhort petioles, ovate, acuminate, entire, ſmooth, pale underneath, an inch long, the odd lobe on a longer petiole. The flowers from the ſame bud with the leaves, in racemes often a foot in length. Pedicels ſcattered, oppoſite and alternate, ſhort, one-flowered. It varies with white and with purple corollas; with larger hirſute, and with ſmaller ſmooth legumes.

Native of Japan, where it is frequently cultivated for arbours [c]. Alſo of Virginia.

27. Native of New South Wales. Introduced 1781, by Sir Joſeph Banks, Bart.—Shrubby [d].

28. Native of Jamaica [e].

29. Roots ſubtuberous, hard, long, in bundles. Stem long, branched. Leaflets large, tomentoſe, entire. Flowers wholly purple, in long lateral ſpikes. Stamens five longer, with oblong anthers, five alternately ſhorter, with roundiſh anthers. Legume linear, ſtraight, compreſſed, ſeparated between the ſeeds; which are compreſſed and ſuborbiculate.

Native of the mountain woods of Cochinchina.

This ſpecies is very nearly allied to D. bulboſus and trilobus, eſpecially in the tuberous root, linear legumes divided between the ſeeds, ſtyles and ſtigmas not pubeſcent. Had not Linneus ranged theſe under Dolichos, Loureiro would have ſuppoſed that all three belonged to another genus.

30. Stem annual, long, round, branched. Leaves three-nerved, ſmooth. Flowers yellow, axillary, on long, ſtriated peduncles. Legume linear, ſtraight, ſubcylindric. Seeds ovate, pale, eſculent. Cultivated on the eaſtern coaſt of Africa [f].

31. Stem ſmooth, woody, angular at top. Leaflets oval, the end one roundiſh; entire, emarginate, veined: petiole a little longer than the leaflets, ſcarcely hairy; petiolules purple, hairy. Racemes axillary, half a foot long. Peduncles with remote tubercles, almoſt as big as Coriander ſeeds, purple at top. Flowers two or three at each tubercle, on very ſhort pedicels. Bractes two, roundiſh, caducous, at the baſe of the flower. Calyx bell-ſhaped, ſmooth. Corolla large, purple. Legumes three inches long, oblique at both ends, acute, with very minute hairs preſſed cloſe. — D. altiſſimus differs from this in having the calyxes and wings villoſe at the baſe [g].

32. Stem perennial, ſuffruticoſe, ſcandent, long, branched, ſmooth. Leaflets acute, wrinkled, ſmooth. Stipules briſtle-ſhaped, very ſmall. Flowers violet-coloured, on many-flowered, axillary peduncles. Calyx tubular, two-lipped: upper-lip bifid; lower three-toothed, ſhorter. Wings and keel ſickle-ſhaped, equal to the ſtandard. Filaments equal, with ovate, nodding anthers. Legume large, compreſſed, thicker at the back, three-nerved, reflex at the tip, acuminate. Seeds five or ſix, large, compreſſed-ovate.

Native of China and Cochinchina; cultivated for arbours, not for food.—There is a variety, with legumes twice as long, and flatter, with blunter leaves, and other minute differences [h].

Here are two ſpecies, this and n. 8. bearing the ſame name. They are however different; that probably from the Weſt, this from the Eaſt Indies. The plant of Rumphius (t. 135. f. 1.) probably belongs to this; but whether it is Thunberg's enſiformis (p. 279.) I cannot ſay. Kæmpfer's *Kerdir* is referred by him to D. lineatus. See Kæmpf. ic. ſelect. t. 25.

Native of the Eaſt Indies. Introduced 1778, by Mr. William Roxburgh [i].

33. Stem round at bottom and ſmooth; above ſtriated, very hirſute, a foot and more in height. Leaves petioled, hirſute: leaflets petioled, ovate, obtuſe with a point, entire, the middle one on a longer petiole and larger, an inch in length: petiole ſtriated, hirſute, a finger's length. Flowers in ſhort, erect, hirſute racemes: ſubſeſſile, from three to five together. Corollas purple, ſcarcely larger than the calyx [k].

Native of the Eaſt Indies, Ceylon, Japan, &c.

The ſeeds, which are uſually called *Miſo* in Japan, are put into ſoups, and are the moſt common diſh there, inſomuch that the Japoneſe frequently eat them three times a day. The *Soia* of the Japoneſe, which is preferred to the *Kiſiap* of the Chineſe, is prepared from theſe ſeeds, and is uſed in almoſt all their diſhes, inſtead of common ſalt. The Chineſe alſo have a favourite diſh made of theſe ſeeds, called *Tou hu* or *Tau hu*, which looks like curd, and though inſipid in itſelf, yet with proper ſeaſoning is agreeable and wholeſome [l].

34. Stem annual, a foot and half high, roundiſh, rugged, branched. Leaflets broad-lanceolate, ſmooth. Common petiole long. Stipules lanceolate, minute. Flowers ſubterminating, two or three together, on a very long peduncle. Legume linear, four inches long, ſubcylindric, ſlender, ſmooth. Seeds oblong-ovate, ſomewhat compreſſed, with a ſcar of a different colour. There are ſeveral varieties differing in the colour of the flower and ſeed, all which are much cultivated for food [m].

Native of the Eaſt Indies.

35. Stem ſuffruticoſe, a foot and half high, erect, branched, hairy. Root an ovate brown tuber. Leaves linear-lanceolate, quite entire, veined, pubeſcent on both ſides, ſubſeſſile. Flowers yellow, axillary. Peduncles erect. Stipules in pairs, lateral, ſubulate, long. Legume hirſute, cartilaginous, inflated, two-ſeeded [n].

Native of India, (and China.) Introduced 1778, by M. Thouin [o].

36. Common by the ſea-ſide in Jamaica. The root is a ſtrong purgative [p].

37. Native of Jamaica.

[a] Smith ſpicil. [b] Hort. kew. [c] Thunberg. [d] Hort. kew. [e] Swartz. [f] Loureiro. [g] Vahl. [h] Loureiro. [i] Hort. kew. [k] Thunb. and Lam. [l] Thunb. and Loureiro. [m] Loureiro. [n] Ibid. [o] Hort. kew. [p] Browne.

38. Root annual. Stem ſimple, with lines running down from the petiole, villoſe, rugged, herbaceous, a foot high, the thickneſs of a quill. Leaves alternate, ſpreading, four inches long; lateral leaflets oppoſite, ſcarcely petioled, the end one more produced and petioled; they are ovate, acute with a minute point, ſubangular and toothed, nerved, thick, brittle, two inches and a half long. Petioles three-ſided, channelled. Stipules linear, very acute, villoſe, erect, permanent. Spikes axillary, ſolitary, erect, villoſe, ſhorter than the petioles: flowers ſubſeſſile, erect, purple. Bractæ awl-ſhaped, erect, under each flower. Filaments all connate, five ſcarcely ſhorter than the others, with peltate anthers; on the longer ones ovate, acuminate, two-celled. Legumes acuminate, compreſſed, ſilky. Seeds ſeven or eight, orbicular, ſubcompreſſed, brown, ſeparated by tranſparent membranes.

Native of the Eaſt Indies[a].

PROPAGATION AND CULTURE.

Moſt of the ſpecies, coming from the Eaſt and Weſt Indies, are tender, and ſeldom perfect their ſeeds in England. Being moſtly annual plants, they are frequently loſt in our ſtoves, and recovered again as the ſeeds are ſent over. Mr. Miller had probably cultivated moſt of the above, and perhaps many others not known at preſent, in the long courſe of his practice.]

The 12th and 13th are ſometimes preſerved in botanic gardens, eſpecially the latter, whoſe pods are cloſely covered with ſtinging hairs, commonly known by the title of Cow-itch; but theſe are too tender to thrive in the open air in this country, ſo that whoever is deſirous to have the plants, ſhould ſow their ſeeds in a hot-bed in march; and when the plants are come up, they ſhould be each planted in a ſeparate pot, and plunged into the hot-bed again, being careful to ſhade them till they have taken root; after which they muſt have freſh air every day admitted to them, in proportion to the warmth of the ſeaſon; and when the plants are too tall to remain in the hot-bed, they ſhould be removed into the bark-ſtove, where, if they are allowed room to run, they will flower and perfect their ſeeds.

2. 4. Theſe, with ſeveral other ſpecies are cultivated in warm countries for the table, but in England theſe ſeldom perfect their ſeeds; and were they to thrive here as well as in the warm countries, they would be little eſteemed, becauſe we have much better ſorts in our gardens already; for the ſcarlet flowering Kidney Bean is preferable to all of them for eating, and deſerves our care to cultivate it more than any other.

[35. This is eaſily propagated by ſeed, and produces abundance of flowers during ſummer in a ſtove[b].

38. This alſo ripens its ſeed, and may be propagated that way[c]. And ſo doubtleſs may many of the other ſorts, in a good ſtove.

DOLICHOS TRILOBATUS. See *Glycine triloba*.

DOLIOCARPUS.

Rolander in act. holm. 1756. *Lin. gen. Schreb. n.* 874. *Juſſ.* 433.

Calinca. *Aubl. t.* 221. *Juſſ.* 434.

Claſſ. 13. 1. Polyandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved: *leaflets* oblong-rounded, concave, unequal, coloured, permanent.

COR. *Petals* three, roundiſh, concave, plaited.

STAM. *Filaments* very many, inſerted into the receptacle, capillary. *Anthers* compreſſed.

PIST. *Germ* globular. *Style* long, incurved. *Stigma* compreſſed, flat, ſubbifid.

PER. *Berry* globular, one-celled, crowned with the ſtyle.

SEEDS two, arilled, oblong-rounded, flat on one ſide, convex on the other.

OBS. *Aublet aſcribes to his* Calinca *a one-leafed, three-parted calyx, with two ſmaller acceſſory ſegments, which he calls bractes; it ſeems however not to be generically diſtinguiſhed from* Doliocarpus.

Somma *of Aublet* 219. *differs in having the ſegments of the calyx almoſt equal; five petals; a one-celled berry; and a ſingle ſeed; but it may be doubted whether theſe diſtinctions be ſufficient to make it a different genus.*

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* three-petalled, plaited. *Stigma* ſubbifid. *Berry* globular, crowned with the ſtyle, one-celled, two-ſeeded.

SPECIES.

1. Doliocarpus Rolandri.
Gmel. Linn. ſyſt. 2. 805. *Roland. in act. holm.* 1756. *p.* 261.
Stem ſtiff and ſtraight, leaves ovate-lanceolate toothed, flowers terminating.

2. Doliocarpus major.
Gmel. Linn. ſyſt. 2. 805. *Roland. in act. holm.* 1756. *p.* 261.
Stem ſcandent, leaves ovate toothed, peduncles lateral one-flowered.

3. Doliocarpus Calinca.
Gmel. Linn. ſyſt. 2. 805. *Aubl. guian.* 1. 557. *t.* 221.
Stem ſcandent, leaves ovate quite entire, flowers axillary in bundles.

DESCRIPTIONS, *&c.*

1. This grows to a ſhrub: ſtem and branches upright: leaves hanging. They are of an oval-lanceolate ſhape, and dentated.

2. The flowers are aromatic, but rather nauſeous; the berries of this plant are pernicious. Stem ſlender and flexuoſe; branches at right angles: leaves ſpreading[a].

3. A ſhrub, with ſeveral knotty ſpreading twigs, ſcattering over the neighbouring trees: the branches are garniſhed with alternate, oval, ſhining green leaves terminating in a point: the largeſt are four inches long. The flowers ſpring from the boſoms of the leaves on the branches, and are arranged alternately in little heaps. The corolla conſiſts of three white petals, which are large and rounded.

Native of Guiana[b].

DOMBEYA. (*So named in memory of Joſ. Dombey, who travelled into Peru, Chili, &c.*)

Claſſ. 22. 13. Dioecia Monadelphia.

Nat. order of *Coniferæ*.

Lin. gen. Schreb. n. 1551. *Lamarck. encycl.* 2. 301.

Araucaria. *Juſſ.* 413.

GENERIC CHARACTER.

* *Male.*

CAL. *Ament* ovate-cylindric, imbricate with very many woody ſhort *ſcales*, each terminated by a lanceolate, acute coriaceous *leaflet*, concave at bottom, narrower and recurved at top.

Perianth none.

COR. none.

STAM. *Filaments* none, except the amentaceous ſcales. *Anthers* ten or twelve, heaped about each amentaceous ſcale, linear, grooved, the length of the ſcale, faſtened to the top of it, below the leaflet by the upper extremity, approximating and converging round the ſcale, ſeparating by the lower extremity when the ſcale is broken.

* *Female.*

CAL. *Ament* large, roundiſh ovate, cloſely imbricate with very many germs, reſembling ſcales.

Perianth none.

COR. none.

PIST. *Germ* each wedge-form-oblong, ſubcompreſſed, contracted at the baſe into a point, with a broad, thick, callous termination. *Style* none. *Stigma* bivalve, the valves unequal: the inner very ſmall, obtuſe, the outer very large, broad at the baſe, thick, curved inwards above the inner one, terminated by a linear, acute, ſlender, aſcending ſtrap, almoſt the length of the germ, bent in at a right angle above the germ.

[a] L'Heritier. [b] Smith. [c] L'Heritier.

[a] Rolander. [b] Aublet.

PER. none.
SEEDS very many, heaped into a roundiſh ſtrobile, imbricate: each oblong, ſubcylindric, towards the baſe obtuſely four-cornered, with a ſhort broad ſpatulate wing or ſtrap at the top, thickened at the edge, incurved, aſcending: the ſhell coriaceous, coloured, valveleſs; the kernel oblong, ſubangular at the baſe. *Receptacle* naked, villoſe, here and there alveolate.

ESSENTIAL CHARACTER.

MALE. Calyx of the *ament* ſcales, terminated by a leaflet. *Cor.* none. *Anthers* ten or twelve without filaments.
FEM. *Cal.* Ament with many germs. *Cor.* none. *Stigma* bivalve, unequal. *Seeds* many, in a roundiſh ſtrobile.

SPECIES.

1. Dombeya Chilenſis.
Lamarck. encycl. vol. 2. p. 301.
Turbinate imbricate leaves, mucronated on one ſide: the branches quaternate, and cruciate.

DESCRIPTION.

This is a tree as yet very little known; a native of Chili, of a reſinous nature, in ſome reſpects allied to Protea; and alſo to the Pines in ſome particulars of its fructification. The trunk is ſtraight and of conſiderable height: the wood white, ſolid, and clothed with a kind of double bark. The boughs are covered with very numerous leaves, ſeſſile, oval, very pointed, entire, ſmooth and coriaceous: a little concave inwards, and convex outwards; they have a ſharp point, and are ranged on the branches in the manner of ſcales. The flowers are male and female, borne on different individuals, and hang in ſeſſile ſolitary catkins from the tops of the branches.

DOMBEYA L'Herit. See *Fourcroya*.
DONATIA. (*So named by Forſter from Vitaliano Donati of Padua, profeſſor of botany at Turin. He travelled into Egypt and Arabia, and died in his journey.*)

Stem naked very simple one-flowered.

DESCRIPTIONS, *&c.*

1. Great Leopard's Bane has thick fleshy roots, divided into many knots, sending out strong fleshy fibres, which penetrate deep into the ground. Root-leaves heart-shaped, hairy, petioled: among these arise the flower-stalks, which are channelled and hairy, near three feet high, putting out one or two smaller stalks from the side; these grow erect, and have one or two heart-shaped leaves closely embracing the stalk; this and each branch is terminated by one large yellow flower. These appear in may; and the seeds ripen in july.

[The scales of the calyx are about twenty-six. The florets of the ray are streaked with green lines, and are from twenty-two or twenty-four to thirty in number; in the disk are about 178. Seeds of the ray nearly triangular, and streaked with ten lines: those of the disk roundish, hairy and crowned with a down which is slightly plumose. Receptacle convex and hairy. From the bursting of the anthers to the ripening of the seeds takes up the space of one month [a]. The stem-leaves towards the base become narrower, and then again widen into ears clasping about the stem, so as to be in a manner appendicled. In the great smooth variety, they are obscurely serrate, three or four inches broad, and near a span in length; whereas in the smaller one they are scarcely half the length and breadth [b].

Native of France, Switzerland, Germany, Austria, Carniola, Hungary, Savoy, where I gathered it on M. Saleva, Piedmont. This is one of the plants which from the facility with which it propagates itself has lately escaped from the gardens to increase the British Flora. Mr. Lightfoot remarked it in Scotland, but always near houses; and Dr. Stokes near Duplin house.

This plant has been stigmatised as poisonous, seemingly without much reason. It had its name *Pardalianches* (παρδαλις, *a leopard*, and αγχω, *to strangle*) from this supposed noxious quality. The famous Conrad Gesner however took two drams of the root without injury. Others on the contrary would persuade us that it is an antidote to poison, but they are still farther from the truth. It is not used in the present practice. Dr. Stokes informs us that two drams occasioned a sense of inflation in the stomach, and of general weakness, but that these symptoms were of short duration. That it has been recommended in vertigo, epilepsy, and menstrual obstructions, but that these powers want the confirmation of a more accurate experiment [c].

As the Austrian plant differs from the common one chiefly in having a more woody root that spreads but little, it is no more than a variety [d].]

2. The leaves of Plaintain-leaved Leopard's Bane are indented on their edges towards their base, but their upper parts are entire. The stalks rise about two feet high; each is terminated by a large yellow flower, like that of the preceding: they have two or three alternate, embracing leaves, not so hairy as those of the former sort. It flowers about the same time; and grows naturally in Germany, France, Spain, and Portugal.

[These were both cultivated in 1597 by Gerarde.]

3. This has a perennial root, as well as the two preceding. The leaves are like those of the common Daisy, but longer, and not so broad. The flower grows on a naked stalk near a foot long, and the root seldom sends out more than one stalk. The ray of the flower is white, and very like that of Common Daisy; the disk is yellow.

[Root-leaves many, gradually lessening to the petiole, lanceolate or obovate, quite entire or toothed here and there, hirsute, thickish, pale green. Among these arise the scapes, half a foot or a span in height, slender, hirsute, round, purplish, erect, one-flowered. Calyx smoothish, the length of the disk of the flower; leaflets eighteen or twenty. Florets in the ray quite entire or with two teeth, spreading very much. Germ crowned only with a down, not with scales. Down of the seeds sessile, plumose. Receptacle convex [e].—The seeds of the ray are downy in this [f].

On the Swiss, Tyrolese and Italian alps; in Austria, Carniola, Silesia. I gathered it by the Bois de Batie near Geneva, april 22, 1779, in flower. Haller found it in the lower alps with a deep red flower. Cultivated by Mr. Miller, in 1759 [g].] He received it from Verona.

PROPAGATION AND CULTURE.

1. This plant multiplies very fast by its spreading roots, and if the seeds are permitted to scatter, they will produce plants wherever they happen to fall, so that it becomes a weed where it is once established; it loves a moist soil and a shady situation.

2. The second is equally hardy, and multiplies in as great plenty.

3. This is propagated by parting the roots, for the seeds do not ripen well in England. It must have a shady situation and a moist soil. The flowers do not make a much better appearance than those of the common Daisy, only they stand on much taller stalks.

DORONICUM. See *Arnica, Rudbeckia, Senecio, Septas,* and *Tussilago.*

——— helveticum. See *Senecio Doronicum.*

DORSTENIA. (*So named by Plumier, from Theodorus Dorstenius, a German physician, who published a history of plants, or Botanicon,* 1540.)

Lin. gen. n. 158. *Reich.* 166. *Schreb.* 209. *Plum.* 8. *Houst. A. A.* 421. *t.* 12. *Juss.* 401.

Class. 4. 1. Tetrandria Monogynia.

Nat. order of *Scabridæ.*—*Urticæ* Juss.

GENERIC CHARACTER.

CAL. *Receptacle common* one-leafed, flat, cornered, very large, covered by the receptacle, with very numerous floscules inhabiting the disk, very small.

Perianth proper four-cornered, concave, imbedded in the receptacle and united with it.

COR. none.

STAM. *Filaments* four, filiform, very short. *Anthers* roundish.

PIST. *Germ* roundish. *Style* simple. *Stigma* obtuse.

PER. none. *Receptacle common* becoming fleshy.

SEEDS solitary, roundish, acuminate.

OBS. *Those who have opportunity of examining the living plant would do well to observe whether any other female floscules are intermixed with the hermaphrodites, as in* Parietaria; *for* Dorstenia *seems intermediate between* Ficus *and* Parietaria, *and as it were a Fig expanded.*——*Swartz has observed monœcious flowers.*

ESSENTIAL CHARACTER.

Recept. common one-leafed, fleshy, in which solitary seeds nestle.

SPECIES.

1. Dorstenia Houstoni.

Lour. cochinch. 90.

Pedunckes cauline, petioles three or five-leaved.]

DESCRIPTIONS, *&c.*

1. This ſort ſends out ſeveral angular heart-ſhaped leaves from the root, which have foot-ſtalks eight or nine inches in length and very ſlender; the leaves are about three inches and a half long, and almoſt four broad at their baſe, the two ears having two or three angles which are acute, and the middle of the leaves are extended and end in acute points like a halbert; theſe are ſmooth and of a lucid green: the foot-ſtalk which ſuſtains the placenta is nine inches long, and about half an inch ſquare, and the upper ſurface cloſely ſet with ſmall flowers.

Native of Campeachy in South America. Found there on rocky grounds by Dr. Houſtoun, and cultivated by Mr. Miller before 1733.

2. The ſecond ſends out ſeveral leaves from the root, which are about four inches long, and as much in breadth; theſe are deeply laciniated into five or ſeven obtuſe parts, ſtanding upon foot-ſtalks near four inches long; they are ſmooth, and of a deep green. The ſtalk ariſes from the root, and grows near four inches high, upon which the fleſhy placenta is vertically placed; this is of an oval form about one inch long, and three quarters broad. Upon the upper ſurface of this, the ſmall flowers are cloſely ſituated, the fleſhy part becoming an involucre to them; theſe are very ſmall, and ſcarce conſpicuous at a diſtance, being of an herbaceous colour.

[Native of New Spain, Mexico, Peru, the iſlands of Tobago and St. Vincent *.] Mr. Miller ſays that it was diſcovered by his ingenious friend Dr. William Houſtoun, near old Vera Cruz in New Spain.

3. The third ſort ſends out leaves of different forms; ſome of the lower leaves are heart-ſhaped, having a few indentures on their edges, and ending in acute points, but the larger leaves are deeply cut like the fingers on a hand, into ſix or ſeven acute ſegments. Theſe leaves are five inches long, and ſix broad in the middle; they are of a deep green, and ſtand upon long foot-ſtalks. The placenta is very thick and fleſhy, an inch and a half long, and three quarters broad, having four acute corners; theſe have a number of ſmall flowers, placed on the upper ſurface like the other ſpecies.

Linnæus ſays it is a native of Vera Cruz; but Mr. Miller informs us that it was found in great plenty in the iſland of Tobago, by Mr. Robert Millar, ſurgeon. He alſo affirms, that the roots of all the three ſpecies are brought over indifferently, to be uſed in medicine and in dyeing; and that it was not known what the plant was, the roots of which were imported, and had been long uſed in medicine, until Dr. Houſtoun informed us; for although father Plumier had diſcovered one ſpecies, and had given the name of Dorſtenia to it, yet he ſeems not to have known, that the Contrayerva was the root of that plant.

[4. This appears to be a ſmall plant, with leaves proceeding irregularly from the ſtem, which is ſhort; they are ovate-acute and pretty ſtrongly dentated at the edges. The male flowers are collected into little heads, and the females into a kind of ſharply lobed or irregular flattiſh heads. The leaves ſtand on remarkably long foot-ſtalks †.

5, 6. Theſe are natives of the Society Iſles. Forſter, ſuppoſing them to be of a different genus from this, named them Elatoſtema, from ἐλατὸς elaſtic, and στῆμα a ſtamen; becauſe the ſtamens are elaſtic.

7. Receptacle plano-convex, with a crenate dotted margin, and fleſhy. Diſk a little concave. Male flowers in the diſk towards the ray. Calyxes immerſed in the receptacle, or four-toothed holes. Filaments two, three, or four ſhort; with twin anthers. Flowers in the middle of the diſk female: calyxes immerſed, or four-toothed, four-cornered holes. Germ ovate: ſtyle bifid: ſtigmas reflex. When the germ is ripe it is concealed within the receptacle, and opens into two parts, dropping the ſeed, which is roundiſh. It is clearly allied to Urtica and Parietaria.

Native of Jamaica and St. Domingo ‡.

8. Root fuſiform, three inches long, white within and without, fleſhy, aromatic. Stem perennial, ſuberect, round, ſimple, whitiſh. Leaves ternate or quinate, lanceolate, quite entire, ſmooth, on a long common petiole. Receptacle of the flowers lateral, fleſhy, ſuboval, with many florets put forth at the top: the calyx is funnel-form, and three-toothed.

Native of China in the northern provinces; and called there *Pechi* and *Bach-chi*. The root is aromatic, and is uſed in medicine ‖.]

PROPAGATION AND CULTURE.

It will be difficult to obtain theſe plants, becauſe the ſeeds are ſeldom to be found good; nor will they grow, if they are kept long out of the ground; ſo that the only ſure method to obtain them is, to have the roots taken up at the time when their leaves begin to decay, and planted pretty cloſe in boxes of earth, which may be brought very ſafe to England, provided they are preſerved from ſalt water, and are not over-watered with freſh water in their paſſage. When the plants arrive, they ſhould be tranſplanted each into a ſeparate pot filled with freſh earth, and plunged into the bark-ſtove, which ſhould be kept of a moderate heat; and the plants muſt be frequently refreſhed with water during the ſummer ſeaſon; but in winter, when the leaves are decayed, it ſhould be given to them more ſparingly. With this management theſe plants may not only be maintained, but may alſo be increaſed by parting their roots in the ſpring, before the plants put out their leaves.

* Linn. † Plumier. ‡ Swartz. ‖ Loureiro.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, turbinate, half-six-cleft, permanent: *segments* ovate, acute, coloured.

COR. none.

Nectaries six, ovate on the outside with two oblong pits, on the inside convex, anther-bearing: terminated by two glands, convex without, concave within; ending at bottom in a capillary pedicel, shorter than the calyx, inserted at the base of the segments, with a villose gland on each side at the insertion of it.

STAM. *Filaments* none. *Anthers* very many, minute, one-celled, with the valve opening at the base.

PIST. *Germ* ovate, superior. *Style* filiform, the length of the stamens. *Stigma* six-cleft.

PER. *Berry* ovate, acute, one-celled.

SEED single, with a brittle shell.

OBS. *It is allied to* Porostema. *The fructification is extremely singular. The fruit aromatic.*

ESSENTIAL CHARACTER.

Cal. half-six-cleft. *Cor.* none. *Nect.* six. *Filaments* none. *Germ* superior. *Stigma* six-cleft. *Berry* ovate, one-celled. *Seed* one, with a brittle shell.

SPECIES.

1. Douglassia Guianensis. *Guiana Douglassia. With alternate, lanceolate leaves.*

DESCRIPTION, *&c.*

1. This, the only species, is a middling fized shrub, growing in Guiana; it is about five feet high, and branching at top: its diameter five or six inches: the wood white and compact. The branches are subdivided into smaller ones; the flowers grow at their extremities in a kind of straggling clusters, and are small and yellowish.

DOUGLASSIA Houst. See *Volkameria.*

DRABA. (*From* δραβη, *acrid*, Lin. *It is a name of Dioscorides.*)

Engl. *Whitlow-grass.* Fr. *Drave.*

Lin. gen. n. 800. *Reich.* 864. *Schreb.* 1076. *Gærtn. t.* 141. *Dill. gen.* 122. *Juss.* 240.

Class. 15. 1. Tetradynamia Siliculosa.

Nat. order of *Siliquosæ* or *Cruciformes. Cruciferæ* Juss.

GENERIC CHARACTER.

CAL. *Perianth* four-leaved; *leaflets* ovate, concave, from erect spreading; deciduous.

COR. four-petalled, cruciform. *Petals* oblong, somewhat spreading; with very small claws.

STAM. *Filaments* six, length of the calyx: of these the four opposite ones somewhat longer, from erect spreading. *Anthers* simple.

PIST. *Germ* ovate. *Style* scarce any. *Stigma* headed, flat.

PER. *Silicle* elliptic-oblong, compressed, entire, destitute of style, two-celled; *dissepiment* parallel with the valves. *Valves* plano-concave.

SEEDS several, small, roundish.

OBS. *In some species the petals are two-parted to the very claws, in others only emarginate at the tip, in others perfectly entire.*

The essential character consists in the silicle, which is of an oval-oblong compressed form, almost destitute of style: hence it is easily distinguished from Alyssum, Subularia, *and* Lunaria.

ESSENTIAL CHARACTER.

Silicle entire, oval-oblong; valves flattish, parallel to the dissepiment. *Style* none.

Stem-leaves numerous hoary, ſilicles oblong obliquè ſubſeſſile.

DESCRIPTIONS, *&c.*

1. [It very much reſembles *D. alpina*, from which however it differs, in the leaves being even, linear, keeled, ciliate; not oval-oblong, rough-haired, without any keel. It differs from *D. ciliaris* in having the root-leaves forming a cloſe tuft, giving it the air of a Sedum; the keel even; not alternate leaves on the branches ſpreading, and a ciliate keel. The flowers alſo are yellow, as in *D. alpina*, not white [a].

Root perennial. Stem three inches high. Petals entire. Silicle hairy, rough, ovate, ſharp at both ends, ending in a long ſtyle [b]; four lines in length; the cells having ſix to eight ſeeds, which are round and flatted [c].

The leaves are extremely ſmooth, ſhining green, ſet round with ſtiff hairs regularly diſpoſed, ſome only two lines long and half a line broad; others an inch long and a line broad. Scape even, one and two inches high, or more. Flowers in a ſort of corymb, which becomes a raceme when the fruit is ripe. Calyx ſmooth; leaflets fleſhy, green, commonly coloured on the edge, which is membranaceous. Petals yellow, uſually entire. Silicle a line and half wide, five lines long with the point, green, ſometimes pubeſcent with hairs preſſed cloſe, but more frequently ſmooth or netted-veined [d].

It is well adapted to rockwork, and is a pretty plant with a pleaſant ſmell.

Native of the mountains of France, Switzerland, Savoy, Auſtria, Carniola, Sileſia, *&c.* I gathered it on M. Saleve near Geneva, april 13, 1779; where Ray alſo mentions that it grows. In our gardens it flowers ſo early as february.—Cultivated in 1731, by Mr. Miller [e].

2. Root perennial. Root-leaves forming a cloſe tuft, imbricate, crowded, even, keeled, diſtinctly ciliate. Petals obovate, white. Style longer than the ſtamens. It differs from the foregoing, in the leaves being narrower and ſmooth, and the petals not in the leaſt emarginate. In a ſtate of cultivation it branches out with remote leaves [f].

Gerard (in ſl. Gallo-Provinc.) thus deſcribes it. Stem flaccid, ſlender, diffuſed, diaphanous, half a palm in height, branched at bottom, naked at top. Leaves elegantly ciliate, forming roſes next the ground, and gradually becoming more remote higher up, ſeſſile, keeled beneath, ending in a ſharpiſh point. Peduncle naked, the length of the ſtem, filiform, few-flowered. Flowers terminating, ſubſeſſile: leaflets of the calyx erect, almoſt equal, lanceolate, obtuſe, green on the outſide, yellowiſh on the inſide. Petals obovate, twice as long as the calyx, with claws the length of the calyx. Filaments erect, briſtle-ſhaped, almoſt equal, the length of the petals: anthers oblong, pale. Germ ovate: ſtyle longer than the ſtamens.

Native of Provence, in dry rocky places.

3. Perennial. All the root-leaves ſpreading, ſprinkled with hairs on the upper ſurface, diſpoſed as in *Androſace*; by no means imbricate, linear, ciliate, or ſmooth on the upper ſurface. Stem leaſleſs, with a few hairs ſcattered about it; not one-leaſed or ſmooth. Petals ſlightly emarginate, not entire [g].

Gouan thus diſtinguiſhes this from the firſt ſort. It has fewer leaves, ovate, a little longer, very often toothed towards the end, and rough with hairs. Stems often naked, but ſometimes it has a leaf or two on it; this alſo is rough with hairs. Flowers ſubracemed, at firſt corymbed. Calyx hairy; the leaflets membranaceous and coloured at the edge, as in D. aizoides. Petals a little emarginate. The leaves are repreſented quite entire in Oeder's figure, which is otherwiſe a good one.
